call psstebz(*ictxt*, *range*, *order*, *n*, *vl*, *vu*, *il*, *iu*, *abstol*, *d*, *e*, *m*, *nsplit*, *w*, *iblock*, *isplit*, *work*, *iwork*, *liwork*, *info*)

call pdstebz(*ictxt*, *range*, *order*, *n*, *vl*, *vu*, *il*, *iu*, *abstol*, *d*, *e*, *m*, *nsplit*, *w*, *iblock*, *isplit*, *work*, *iwork*, *liwork*, *info*)

Include Files

Description

The p?stebz routine computes the eigenvalues of a symmetric tridiagonal matrix in parallel. These may be all eigenvalues, all eigenvalues in the interval [*vlvu*], or the eigenvalues indexed *il* through *iu*. A static partitioning of work is done at the beginning of p?stebz which results in all processes finding an (almost) equal number of eigenvalues.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.
Notice revision #20201201

Input Parameters

ictxt (global) INTEGER. The BLACS context handle.

range (global) CHARACTER. Must be 'A' or 'V' or 'I'.

If *range* = 'A', the routine computes all eigenvalues.

If *range* = 'V', the routine computes eigenvalues in the interval [*vl*, *vu*].

If *range* ='I', the routine computes eigenvalues with indices *il* through *iu*.

order (global) CHARACTER. Must be 'B' or 'E'.

If *order* = 'B', the eigenvalues are to be ordered from smallest to largest within each split-off block.

If *order* = 'E', the eigenvalues for the entire matrix are to be ordered from smallest to largest.

n (global) INTEGER. The order of the tridiagonal matrix T ($n \geq 0$).

vl, *vu* (global)

REAL for psstebz

DOUBLE PRECISION for pdstebz.

If *range* = 'V', the routine computes the lower and the upper bounds for the eigenvalues on the interval [*1*, *vu*].

If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, *iu* (global)

INTEGER. Constraint: $1 \leq il \leq iu \leq n$.

If *range* = 'I', the index of the smallest eigenvalue is returned for *il* and of the largest eigenvalue for *iu* (assuming that the eigenvalues are in ascending order) must be returned.

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol (global)

REAL for psstebz

DOUBLE PRECISION for pdstebz.

The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width *abstol*. If $abstol \leq 0$, then the tolerance is taken as $ulp||T||$, where *ulp* is the machine precision, and $||T||$ means the 1-norm of T

Eigenvalues will be computed most accurately when *abstol* is set to the underflow threshold slamch('U'), not 0. Note that if eigenvectors are desired later by inverse iteration (p?stein), *abstol* should be set to 2*p?lamch('S').

d (global)

REAL for psstebz

DOUBLE PRECISION for pdstebz.

Array of size *n*.

Contains *n* diagonal elements of the tridiagonal matrix *T*. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than the $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

e (global)

REAL for psstebz

DOUBLE PRECISION for pdstebz.

Array of size *n* - 1.

Contains (*n*-1) off-diagonal elements of the tridiagonal matrix *T*. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

work (local)

REAL for psstebz

DOUBLE PRECISION for pdstebz.

Array of size max(5*n*, 7). This is a workspace array.

lwork (local) INTEGER. The size of the *work* array must be ≥ max(5*n*, 7).

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

iwork (local) INTEGER. Array of size max(4*n*, 14). This is a workspace array.

liwork (local) INTEGER. The size of the *iwork* array must ≥max(4*n*, 14, NPROCS).

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

m (global) INTEGER. The actual number of eigenvalues found. 0≤*m*≤*n*

nsplit (global) INTEGER. The number of diagonal blocks detected in *T*. $1 \le nsplit \le n$

w (global)

REAL for psstebz

DOUBLE PRECISION for pdstebz.

Array of size n. On exit, the first m elements of w contain the eigenvalues on all processes.

iblock (global) INTEGER.

Array of size n. At each row/column j where $e(j)$ is zero or small, the matrix *T* is considered to split into a block diagonal matrix. On exit $iblock(i)$ specifies which block (from 1 to the number of blocks) the eigenvalue $w(i)$ belongs to.

NOTE
In the (theoretically impossible) event that bisection does not converge for some or all eigenvalues, *info* is set to 1 and the ones for which it did not are identified by a negative block number.

isplit (global) INTEGER.

Array of size n.

Contains the splitting points, at which *T* breaks up into submatrices. The first submatrix consists of rows/columns 1 to $isplit(1)$, the second of rows/columns $isplit(1)+1$ through $isplit(2)$, and so on, and the $nsplit$-th submatrix consists of rows/columns $isplit(nsplit-1)+1$ through $isplit(nsplit)=n$. (Only the first $nsplit$ elements are used, but since the $nsplit$ values are not known, n words must be reserved for *isplit*.)

info (global) INTEGER.

If $info = 0$, the execution is successful.

If $info < 0$, if $info = -i$, the i-th argument has an illegal value.

If $info > 0$, some or all of the eigenvalues fail to converge or are not computed.

If $info = 1$, bisection fails to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.

If $info = 2$, mismatch between the number of eigenvalues output and the number desired.

If $info = 3$: $range='I'$, and the Gershgorin interval initially used is incorrect. No eigenvalues are computed. Probable cause: the machine has a sloppy floating-point arithmetic. Increase the *fudge* parameter, recompile, and try again.

p?stedc

Computes all eigenvalues and eigenvectors of a symmetric tridiagonal matrix in parallel.

Syntax

```
call psstedc (compz, n, d, e, q, iq, jq, descq, work, lwork, iwork, liwork, info )
call pdstedc (compz, n, d, e, q, iq, jq, descq, work, lwork, iwork, liwork, info )
```

Description

`p?stedc` computes all eigenvalues and eigenvectors of a symmetric tridiagonal matrix in parallel, using the divide and conquer algorithm.

Input Parameters

compz

CHARACTER*1.

= 'N': Compute eigenvalues only. (NOT IMPLEMENTED YET)

= 'I': Compute eigenvectors of tridiagonal matrix also.

= 'V': Compute eigenvectors of original dense symmetric matrix also. On entry, *Z* contains the orthogonal matrix used to reduce the original matrix to tridiagonal form. (NOT IMPLEMENTED YET)

n

(global)

INTEGER.

The order of the tridiagonal matrix *T*. *n* >= 0.

d

(global)

`REAL` for `psstedc`

`DOUBLE PRECISION` for `pdstedc`

Array, size (*n*)

On entry, the diagonal elements of the tridiagonal matrix.

e

(global)

`REAL` for `psstedc`

`DOUBLE PRECISION` for `pdstedc`

Array, size (*n*-1).

On entry, the subdiagonal elements of the tridiagonal matrix.

iq

(global)

INTEGER.

Q's global row index, which points to the beginning of the submatrix which is to be operated on.

jq

(global)

INTEGER.

Q's global column index, which points to the beginning of the submatrix which is to be operated on.

descq

(global and local)

INTEGER.

Array of size *dlen_*.

The array descriptor for the distributed matrix *Q*.

work

(local)

`REAL` for `psstedc`

`DOUBLE PRECISION` for `pdstedc`

Array, size (*lwork*)

lwork

(local)

INTEGER.

The size of the array *work*.

lwork = 6**n* + 2*NP*NQ

NP = `numroc`(*n*, NB, MYROW, DESCQ(*rsrc_*), NPROW)

NQ = `numroc`(*n*, NB, MYCOL, DESCQ(*csrc_*), NPCOL)

`numroc` is a ScaLAPACK tool function.

If *lwork* = -1, the *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum size for the *work* array. The required workspace is returned as the first element of *work* and no error message is issued by `pxerbla`.

iwork

(local)

INTEGER.

Array, size (*liwork*)

liwork

INTEGER.

The size of the array *iwork*.

liwork = 2 + 7**n* + 8*NPCOL

Output Parameters

d

On exit, if *info* = 0, the eigenvalues in descending order.

q

(local)

`REAL` for `psstedc`

`DOUBLE PRECISION` for `pdstedc`

Array, local size (*lld_q*, LOCc(*jq*+*n*-1))

q contains the orthonormal eigenvectors of the symmetric tridiagonal matrix.

On output, *q* is distributed across the P processes in block cyclic format.

work	On output, *work*(1) returns the workspace needed.
iwork	On exit, if *liwork* > 0, *iwork*(1) returns the optimal *liwork*.
info	(global) INTEGER. = 0: successful exit. < 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*. > 0: The algorithm failed to compute the *info*/(*n*+1)-th eigenvalue while working on the submatrix lying in global rows and columns mod(*info*,*n*+1).

p?stein

Computes the eigenvectors of a tridiagonal matrix using inverse iteration.

Syntax

```
call psstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work, lwork, iwork, liwork, ifail, iclustr, gap, info)
call pdstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work, lwork, iwork, liwork, ifail, iclustr, gap, info)
call pcstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work, lwork, iwork, liwork, ifail, iclustr, gap, info)
call pzstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work, lwork, iwork, liwork, ifail, iclustr, gap, info)
```

Include Files

Description

The p?stein routine computes the eigenvectors of a symmetric tridiagonal matrix *T* corresponding to specified eigenvalues, by inverse iteration. p?stein does not orthogonalize vectors that are on different processes. The extent of orthogonalization is controlled by the input parameter *lwork*. Eigenvectors that are to be orthogonalized are computed by the same process. p?stein decides on the allocation of work among the processes and then calls ?stein2 (modified LAPACK routine) on each individual process. If insufficient workspace is allocated, the expected orthogonalization may not be done.

NOTE
If the eigenvectors obtained are not orthogonal, increase *lwork* and run the code again.

p = NPROW*NPCOL is the total number of processes.

Input Parameters

n	(global) INTEGER. The order of the matrix *T* (*n*≥ 0).
m	(global) INTEGER. The number of eigenvectors to be returned.

d, *e*, *w*

(global)

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Arrays:

d of size *n* contains the diagonal elements of *T*.

e of size *n*–1 contains the off-diagonal elements of *T*.

w of size *m* contains all the eigenvalues grouped by split-off block. The eigenvalues are supplied from smallest to largest within the block. (Here the output array *w* from p?stebz with order = 'B' is expected. The array should be replicated in all processes.)

iblock

(global) INTEGER.

Array of size *n*. The submatrix indices associated with the corresponding eigenvalues in *w*: 1 for eigenvalues belonging to the first submatrix from the top, 2 for those belonging to the second submatrix, etc. (The output array *iblock* from p?stebz is expected here).

isplit

(global) INTEGER.

Array of size *n*. The splitting points at which *T* breaks up into submatrices. The first submatrix consists of rows/columns 1 to *isplit*(1), the second of rows/columns *isplit*(1)+1 through *isplit*(2), and so on, and the *nsplit*-th submatrix consists of rows/columns *isplit*(*nsplit*–1)+1 through *isplit*(*nsplit*)=*n*. (The output array *isplit* from p?stebz is expected here.)

orfac

(global)

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

orfac specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues within *orfac**||T|| of each other are to be orthogonalized. However, if the workspace is insufficient (see *lwork*), this tolerance may be decreased until all eigenvectors can be stored in one process. No orthogonalization is done if *orfac* is equal to zero. A default value of 1000 is used if *orfac* is negative. *orfac* should be identical on all processes

iz, *jz*

(global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*.

work

(local). REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Workspace array of size *lwork*.

lwork

(local) INTEGER.

lwork controls the extent of orthogonalization which can be done. The number of eigenvectors for which storage is allocated on each process is *nvec* = floor((*lwork*-max(5*n*,*np*00*mq*00))/*n*). Eigenvectors corresponding to eigenvalue clusters of size (*nvec* - ceil(*m*/*p*) + 1) are guaranteed to be orthogonal (the orthogonality is similar to that obtained from ?stein2).

NOTE
lwork must be no smaller than max(5*n*,*np*00*mq*00) + ceil(*m*/*p*)**n* and should have the same input value on all processes.

It is the minimum value of *lwork* input on different processes that is significant.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

iwork

(local) INTEGER.

Workspace array of size 3*n*+*p*+1.

liwork

(local) INTEGER. The size of the array *iwork*. It must be greater than 3**n* +*p*+1.

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

z

(local)

REAL for psstein

DOUBLE PRECISION for pdstein

COMPLEX for pcstein

DOUBLE COMPLEX for pzstein.

Array of size *descz*(*dlen_*), *n*/NPCOL + NB). *z* contains the computed eigenvectors associated with the specified eigenvalues. Any vector which fails to converge is set to its current iterate after MAXIT iterations (See ?stein2). On output, *z* is distributed across the *p* processes in block cyclic format.

work(1)[0]

On exit, *work*(1) gives a lower bound on the workspace (*lwork*) that guarantees the user desired orthogonalization (see *orfac*). Note that this may overestimate the minimum workspace needed.

iwork

On exit, *iwork*(1) contains the amount of integer workspace required.

On exit, the *iwork*(2) through *iwork*(*p*+2) indicate the eigenvectors computed by each process. Process *i* computes eigenvectors indexed *iwork*(*i*+2)+1 through *iwork*(*i*+3).

ifail

(global) INTEGER. Array of size *m*. On normal exit, all elements of *ifail* are zero. If one or more eigenvectors fail to converge after MAXIT iterations (as in ?stein), then *info* > 0 is returned. If mod(*info*, *m*+1)>0, then for *i*=1 to mod(*info*,*m*+1), the eigenvector corresponding to the eigenvalue *w*(*ifail*(i)) failed to converge (*w* refers to the array of eigenvalues on output).

NOTE
mod(*x*,*y*) is the integer remainder of *x*/*y*.

iclustr

(global) INTEGER. Array of size 2**p*.

This output array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be orthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2*I-1) to *iclustr*(2*I), *i* = 1 to *info*/(*m*+1), could not be orthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr* is a zero terminated array: *iclustr*(2**k*)≠ 0 and *iclustr*(2**k*+1) = 0 if and only if *k* is the number of clusters.

gap

(global)

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

This output array contains the gap between eigenvalues whose eigenvectors could not be orthogonalized. The *info*/*m* output values in this array correspond to the *info*/(*m*+1) clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i-th* cluster may be as high as (*O*(*n*)**macheps*)/*gap*(*i*).

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*),

If the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* < 0: if *info* = -*i*, the *i*-th argument had an illegal value.

If *info* > 0: if mod(*info*, *m*+1) = *i*, then *i* eigenvectors failed to converge in MAXIT iterations. Their indices are stored in the array *ifail*. If *info*/(*m*+1) = *i*, then eigenvectors corresponding to *i* clusters of eigenvalues could not be orthogonalized due to insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

Nonsymmetric Eigenvalue Problems: ScaLAPACK Computational Routines

This section describes ScaLAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

To solve a nonsymmetric eigenvalue problem with ScaLAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained.

Table "Computational Routines for Solving Nonsymmetric Eigenproblems"lists ScaLAPACK routines for reducing the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation $A = QHQ^H$, as well as routines for solving eigenproblems with Hessenberg matrices, and multiplying the matrix after reduction.

Computational Routines for Solving Nonsymmetric Eigenproblems

Operation performed	General matrix	Orthogonal/Unitary matrix	Hessenberg matrix
Reduce to Hessenberg form $A = QHQ^H$	p?gehrd		
Multiply the matrix after reduction		p?ormhr/ p?unmhr	
Find eigenvalues and Schur factorization			p?lahqr, p?hseqr

p?gehrd

Reduces a general matrix to upper Hessenberg form.

Syntax

```
call psgehrd(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pdgehrd(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pcgehrd(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pzgehrd(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

Description

The p?gehrd routine reduces a real/complex general distributed matrix sub(*A*) to upper Hessenberg form *H* by an orthogonal or unitary similarity transformation

Q'*sub(*A*)**Q* = *H*,

where sub(*A*) = *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1).

Input Parameters

n — (global)INTEGER. The order of the distributed matrix sub(*A*) (*n*≥0).

ilo, *ihi* — (global)INTEGER.

It is assumed that sub(*A*) is already upper triangular in rows *ia*:*ia*+*ilo*-2 and *ia*+*ihi*:*ia*+*n*-1 and columns *ja*:*ja*+*ilo*-2 and *ja*+*ihi*:*ja*+*n*-1. (See *Application Notes* below).

If *n* > 0, 1≤*ilo*≤*ihi*≤*n*; otherwise set *ilo* = 1, *ihi* = *n*.

a — (local) REAL for psgehrd

DOUBLE PRECISION for pdgehrd

COMPLEX for pcgehrd

DOUBLE COMPLEX for pzgehrd.

Pointer into the local memory to an array of size (*lld_a*,*LOCc*(*ja*+*n*-1)). On entry, this array contains the local pieces of the *n*-by-*n* general distributed matrix sub(*A*) to be reduced.

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

work

(local)

REAL for psgehrd

DOUBLE PRECISION for pdgehrd

COMPLEX for pcgehrd

DOUBLE COMPLEX for pzgehrd.

Workspace array of size *lwork*.

lwork

(local or global) INTEGER, size of the array *work*. *lwork* is local input and must be at least

lwork≥NB*NB + NB*max(*ihip*+1, *ihlp*+*inlq*)

where NB = *mb_a* = *nb_a*,

iroffa = mod(*ia*-1, NB),

icoffa = mod(*ja*-1, NB),

ioff = mod(*ia*+*ilo*-2, NB), *iarow* = indxg2p(*ia*, NB, MYROW, *rsrc_a*, NPROW), *ihip* = numroc(*ihi*+*iroffa*, NB, MYROW, *iarow*, NPROW),

ilrow = indxg2p(*ia*+*ilo*-1, NB, MYROW, *rsrc_a*, NPROW),

ihlp = numroc(*ihi*-*ilo*+*ioff*+1, NB, MYROW, *ilrow*, NPROW),

ilcol = indxg2p(*ja*+*ilo*-1, NB, MYCOL, *csrc_a*, NPCOL),

inlq = numroc(*n*-*ilo*+*ioff*+1, NB, MYCOL, *ilcol*, NPCOL),

NOTE
mod(*x*,*y*) is the integer remainder of *x*/*y*.

indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a	On exit, the upper triangle and the first subdiagonal of sub(*A*) are overwritten with the upper Hessenberg matrix *H*, and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors (see *Application Notes* below).
tau	(local). REAL for psgehrd DOUBLE PRECISION for pdgehrd COMPLEX for pcgehrd DOUBLE COMPLEX for pzgehrd. Array of size at least max(*ja*+*n*-2). The scalar factors of the elementary reflectors (see *Application Notes* below). Elements *ja*:*ja*+*ilo*-2 and *ja*+*ihi*:*ja*+*n*-2 of the global vector *tau* are set to zero. *tau* is tied to the distributed matrix *A*.
work(1)	On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.
info	(global) INTEGER. = 0: the execution is successful. < 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrix *Q* is represented as a product of (*ihi*-*ilo*) elementary reflectors

Q = *H*(*ilo*)**H*(*ilo*+1)*...**H*(*ihi*-1).

Each *H*(*i*) has the form

H(*i*)= *i* - *tau***v***v'*

where *tau* is a real/complex scalar, and *v* is a real/complex vector with *v*(1:*i*)= 0, *v*(*i*+1)= 1 and *v*(*ihi*+1:*n*)= 0; *v*(*i*+2:*ihi*) is stored on exit in *a*(*ia*+*ilo*+*i*:*ia*+*ihi*-1,*ja*+*ilo*+*i*-2), and *tau* in *tau*(*ja*+*ilo*+*i*-2). The contents of

a(*ia*:*ia*+*n*-1,*ja*:*ja*+*n*-1) are illustrated by the following example, with *n* = 7, *ilo* = 2 and *ihi* = 6:

on entry

$$\begin{bmatrix} a & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & & & & & & a \end{bmatrix}$$

on exit

$$\begin{bmatrix} a & a & a & h & h & h & a \\ & a & h & h & h & h & a \\ & h & h & h & h & h & h \\ & v2 & h & h & h & h & h \\ & v2 & v3 & h & h & h & h \\ & v2 & v3 & v4 & h & h & h \\ & & & & & & a \end{bmatrix}$$

where *a* denotes an element of the original matrix sub(*A*), *H* denotes a modified element of the upper Hessenberg matrix *H*, and *vi* denotes an element of the vector defining *H*(*ja*+*ilo*+*i*-2).

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?ormhr

Multiplies a general matrix by the orthogonal transformation matrix from a reduction to Hessenberg form determined by `p?gehrd`.

Syntax

`call psormhr(`*side*`, `*trans*`, `*m*`, `*n*`, `*ilo*`, `*ihi*`, `*a*`, `*ia*`, `*ja*`, `*desca*`, `*tau*`, `*c*`, `*ic*`, `*jc*`, `*descc*`, `*work*`, `*lwork*`, `*info*`)`

`call pdormhr(`*side*`, `*trans*`, `*m*`, `*n*`, `*ilo*`, `*ihi*`, `*a*`, `*ia*`, `*ja*`, `*desca*`, `*tau*`, `*c*`, `*ic*`, `*jc*`, `*descc*`, `*work*`, `*lwork*`, `*info*`)`

Include Files

Description

The `p?ormhr` routine overwrites the general real distributed *m*-by-*n* matrix sub(*C*)= *C*(*ic*:*ic*+*m*-1,*jc*:*jc*+*n*-1) with

side = `'L'` *side* = `'R'`

trans = 'N':	Q*sub(C)	sub(C)*Q
trans = 'T':	Q^T*sub(C)	sub(C)*Q^T

where Q is a real orthogonal distributed matrix of order *nq*, with *nq* = *m* if *side* = 'L' and *nq* = *n* if *side* = 'R'.

Q is defined as the product of *ihi*-*ilo* elementary reflectors, as returned by p?gehrd.

Q = H(*ilo*) H(*ilo*+1)... H(*ihi*-1).

Input Parameters

side
(global) CHARACTER
='L': Q or Q^T is applied from the left.
='R': Q or Q^T is applied from the right.

trans
(global) CHARACTER
='N', no transpose, Q is applied.
='T', transpose, Q^T is applied.

m
(global) INTEGER. The number of rows in the distributed matrix sub (C) (*m*≥0).

n
(global) INTEGER. The number of columns in he distributed matrix sub (C) (*n*≥0).

ilo, *ihi*
(global) INTEGER.
ilo and *ihi* must have the same values as in the previous call of p?gehrd. Q is equal to the unit matrix except for the distributed submatrix Q(*ia*+*ilo*:*ia*+*ihi*-1,*ja*+*ilo*:*ja*+*ihi*-1).
If *side* = 'L', 1≤*ilo*≤*ihi*≤max(1,*m*);
If *side* = 'R', 1≤*ilo*≤*ihi*≤max(1,*n*);
ilo and *ihi* are relative indexes.

a
(local)
REAL for psormhr
DOUBLE PRECISION for pdormhr
Pointer into the local memory to an array of size (*lld_a*,*LOCc*(*ja*+*m*-1)) if *side* = 'L', and (*lld_a*,*LOCc*(*ja*+*n*-1)) if *side* = 'R'.
Contains the vectors which define the elementary reflectors, as returned by p?gehrd.

ia, *ja*
(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A, respectively.

desca
(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A.

tau
(local)
REAL for psormhr

DOUBLE PRECISION for pdormhr

Array of size *LOCc*(*ja*+*m*-2) if *side* = 'L', and *LOCc*(*ja*+*n*-2) if *side* = 'R'.

tau(*j*) contains the scalar factor of the elementary reflector *H*(*j*) as returned by p?gehrd. *tau* is tied to the distributed matrix *A*.

c

(local)

REAL for psormhr

DOUBLE PRECISION for pdormhr

Pointer into the local memory to an array of size (*lld_c*,*LOCc*(*jc*+*n*-1)).

Contains the local pieces of the distributed matrix sub(*C*).

ic, *jc*

(global) INTEGER. The row and column indices in the global matrix *C* indicating the first row and the first column of the submatrix *C*, respectively.

descc

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work

(local)

REAL for psormhr

DOUBLE PRECISION for pdormhr

Workspace array with size *lwork*.

lwork

(local or global) INTEGER.

The size of the array *work*.

lwork must be at least *iaa* = *ia* + *ilo*; *jaa* = *ja*+*ilo*-1;

If *side* = 'L',

mi = *ihi*-*ilo*; *ni* = *n*; *icc* = *ic* + *ilo*; *jcc* = *jc*; *lwork* ≥ max((*nb_a**(*nb_a*-1))/2, (*nqc*0+*mpc*0)**nb_a*) + *nb_a***nb_a*

else if *side* = 'R',

mi = *m*; *ni* = *ihi*-*ilo*; *icc* = *ic*; *jcc* = *jc* + *ilo*; *lwork* ≥ max((*nb_a**(*nb_a*-1))/2, (*nqc*0+max(*npa*0+numroc(numroc(*ni* +*icoffc*, *nb_a*, 0, 0, NPCOL), *nb_a*, 0, 0, *lcmq*), *mpc*0))**nb_a*) + *nb_a***nb_a*

end if

where *lcmq* = *lcm*/NPCOL with *lcm* = ilcm(NPROW, NPCOL),

iroffa = mod(*iaa*-1, *mb_a*),

icoffa = mod(*jaa*-1, *nb_a*),

iarow = indxg2p(*iaa*, *mb_a*, MYROW, *rsrc_a*, NPROW),

*npa*0 = numroc(*ni*+*iroffa*, *mb_a*, MYROW, *iarow*, NPROW),

iroffc = mod(*icc*-1, *mb_c*), *icoffc* = mod(*jcc*-1, *nb_c*),

icrow = indxg2p(*icc*, *mb_c*, MYROW, *rsrc_c*, NPROW),

iccol = indxg2p(*jcc*, *nb_c*, MYCOL, *csrc_c*, NPCOL),

*mpc*0 = numroc(*mi*+*iroffc*, *mb_c*, MYROW, *icrow*, NPROW),

*nqc*0 = numroc(*ni*+*icoffc*, *nb_c*, MYCOL, *iccol*, NPCOL),

NOTE
mod(*x*,*y*) is the integer remainder of *x*/*y*.

ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c — sub(*C*) is overwritten by *Q**sub(*C*), or *Q*'*sub(*C*), or sub(*C*)**Q*', or sub(*C*)**Q*.

work(1) — On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

info — (global) INTEGER.

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?unmhr

Multiplies a general matrix by the unitary transformation matrix from a reduction to Hessenberg form determined by p?gehrd.

Syntax

call pcunmhr(*side*, *trans*, *m*, *n*, *ilo*, *ihi*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pzunmhr(*side*, *trans*, *m*, *n*, *ilo*, *ihi*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

Include Files

Description

This routine overwrites the general complex distributed *m*-by-*n* matrix sub(*C*) = *C*(*ic*:*ic*+*m*-1,*jc*:*jc*+*n*-1) with

side ='L' *side* ='R'

trans = 'N':	*Q**sub(*C*)	sub(*C*)**Q*
trans = 'H':	Q^H*sub(*C*)	sub(*C*)*Q^H

where *Q* is a complex unitary distributed matrix of order *nq*, with *nq* = *m* if *side* = 'L' and *nq* = *n* if *side* = 'R'.

Q is defined as the product of *ihi*-*ilo* elementary reflectors, as returned by p?gehrd.

Q = *H*(*ilo*) *H*(*ilo*+1)... *H*(*ihi*-1).

Input Parameters

side

(global) CHARACTER

='L': *Q* or Q^H is applied from the left.

='R': *Q* or Q^H is applied from the right.

trans

(global) CHARACTER

='N', no transpose, *Q* is applied.

='C', conjugate transpose, Q^H is applied.

m

(global) INTEGER. The number of rows in the distributed matrix sub (*C*) (*m*≥0).

n

(global) INTEGER. The number of columns in the distributed matrix sub (*C*) (*n*≥0).

ilo, *ihi*

(global) INTEGER

These must be the same parameters *ilo* and *ihi*, respectively, as supplied to p?gehrd. *Q* is equal to the unit matrix except in the distributed submatrix*Q*(*ia*+*ilo*:*ia*+*ihi*-1,*ja*+*ilo*:*ja*+*ihi*-1).

If *side* ='L', then 1≤*ilo*≤*ihi*≤max(1,*m*).

If *side* = 'R', then 1≤*ilo*≤*ihi*≤max(1,*n*)

ilo and *ihi* are relative indexes.

a

(local)

COMPLEX for pcunmhr

DOUBLE COMPLEX for pzunmhr.

Pointer into the local memory to an array of size (*lld_a*,*LOCc*(*ja*+*m*-1)) if *side* = 'L', and (*lld_a*,*LOCc*(*ja*+*n*-1)) if *side* = 'R'.

Contains the vectors which define the elementary reflectors, as returned by p?gehrd.

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

tau

(local)

COMPLEX for pcunmhr

DOUBLE COMPLEX for pzunmhr.

Array of size *LOCc*(*ja*+*m*-2), if *side* = 'L', and *LOCc*(*ja*+*n*-2) if *side* = 'R'.

tau(*j*) contains the scalar factor of the elementary reflector *H*(*j*) as returned by p?gehrd. *tau* is tied to the distributed matrix *A*.

c (local)

COMPLEX for pcunmhr

DOUBLE COMPLEX for pzunmhr.

Pointer into the local memory to an array of size (*lld_c*,*LOCc*(*jc*+*n*-1)).

Contains the local pieces of the distributed matrix sub(*C*).

ic, *jc* (global) INTEGER. The row and column indices in the global matrix *C* indicating the first row and the first column of the submatrix *C*, respectively.

descc (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work (local)

COMPLEX for pcunmhr

DOUBLE COMPLEX for pzunmhr.

Workspace array with size *lwork*.

lwork (local or global)

The size of the array *work*.

lwork must be at least *iaa* = *ia* + *ilo*;*jaa* = *ja*+*ilo*-1;

If *side* = 'L', *mi* = *ihi*-*ilo*; *ni* = *n*; *icc* = *ic* + *ilo*; *jcc* = *jc*; *lwork* ≥ max((*nb_a**(*nb_a*-1))/2, (*nqc*0+*mpc*0)**nb_a*) + *nb_a***nb_a*

else if *side* = 'R',

mi = *m*; *ni* = *ihi*-*ilo*; *icc* = *ic*; *jcc* = *jc* + *ilo*; *lwork* ≥ max((*nb_a**(*nb_a*-1))/2, (*nqc*0 + max(*npa*0+numroc(numroc(*ni* +*icoffc*, *nb_a*, 0, 0, NPCOL), *nb_a*, 0, 0, *lcmq*), *mpc*0))**nb_a*) + *nb_a***nb_a*

end if

where *lcmq* = *lcm*/NPCOL with *lcm* = ilcm(NPROW, NPCOL),

iroffa = mod(*iaa*-1, *mb_a*),

icoffa = mod(*jaa*-1, *nb_a*),

iarow = indxg2p(*iaa*, *mb_a*, MYROW, *rsrc_a*, NPROW),

*npa*0 = numroc(*ni*+*iroffa*, *mb_a*, MYROW, *iarow*, NPROW),

iroffc = mod(*icc*-1, *mb_c*),

icoffc = mod(*jcc*-1, *nb_c*),

icrow = indxg2p(*icc*, *mb_c*, MYROW, *rsrc_c*, NPROW),

iccol = indxg2p(*jcc*, *nb_c*, MYCOL, *csrc_c*, NPCOL),

*mpc*0 = numroc(*mi*+*iroffc*, *mb_c*, MYROW, *icrow*, NPROW),

*nqc*0 = numroc(*ni*+*icoffc*, *nb_c*, MYCOL, *iccol*, NPCOL),

NOTE
mod(*x*,*y*) is the integer remainder of *x*/*y*.

ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c — *C* is overwritten by *Q** sub(*C*) or *Q*'*sub(*C*) or sub(*C*)**Q*' or sub(*C*)**Q*.

work(1)) — On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

info — (global) INTEGER.

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?lahqr

Computes the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form.

Syntax

call pslahqr(*wantt*, *wantz*, *n*, *ilo*, *ihi*, *a*, *desca*, *wr*, *wi*, *iloz*, *ihiz*, *z*, *descz*, *work*, *lwork*, *iwork*, *ilwork*, *info*)

call pdlahqr(*wantt*, *wantz*, *n*, *ilo*, *ihi*, *a*, *desca*, *wr*, *wi*, *iloz*, *ihiz*, *z*, *descz*, *work*, *lwork*, *iwork*, *ilwork*, *info*)

call pclahqr(*wantt*, *wantz*, *n*, *ilo*, *ihi*, *a*, *desca*, *w*, *iloz*, *ihiz*, *z*, *descz*, *work*, *lwork*, *iwork*, *ilwork*, *info*)

call pzlahqr(*wantt*, *wantz*, *n*, *ilo*, *ihi*, *a*, *desca*, *w*, *iloz*, *ihiz*, *z*, *descz*, *work*, *lwork*, *iwork*, *ilwork*, *info*)

Include Files

Description

This is an auxiliary routine used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns *ilo* and *ihi*.

NOTE
These restrictions apply to the use of p?lahqr:

- The code requires the distributed block size to be square and at least 6.
- The code requires A and Z to be distributed identically and have identical contexts.
- The matrix A must be in upper Hessenberg form. If elements below the subdiagonal are non-zero, the resulting transformations can be nonsimilar.
- All eigenvalues are distributed to all the nodes.

Input Parameters

wantt (global) LOGICAL

If *wantt*= .TRUE., the full Schur form *T* is required;

If *wantt* = .FALSE., only eigenvalues are required.

wantz (global) LOGICAL.

If *wantz*= .TRUE., the matrix of Schur vectors *Z* is required;

If *wantz* = .FALSE., Schur vectors are not required.

n (global) INTEGER. The order of the Hessenberg matrix *A* (and *z* if *wantz*). $n \geq 0$.

ilo, *ihi* (global) INTEGER.

It is assumed that *A* is already upper quasi-triangular in rows and columns *ihi*+1:*n*, and that *A*(*ilo*, *ilo*-1) = 0 (unless *ilo* = 1). p?lahqr works primarily with the Hessenberg submatrix in rows and columns *ilo* to *ihi*, but applies transformations to all of *H* if *wantt* is .TRUE.. $1 \leq ilo \leq \max(1, ihi)$; $ihi \leq n$.

a (global)

REAL for pslahqr

DOUBLE PRECISION for pdlahqr

COMPLEX for pclahqr

COMPLEX*16 for pzlahqr

Array, of size (*lld*_a,*). On entry, the upper Hessenberg matrix *A*.

desca (global and local) INTEGER array of size *dlen*_. The array descriptor for the distributed matrix *A*.

iloz, *ihiz* (global) INTEGER. Specify the rows of the matrix *Z* to which transformations must be applied if *wantz* is .TRUE.. $1 \leq iloz \leq ilo$; $ihi \leq ihiz \leq n$.

z (global)REAL for pslahqr

DOUBLE PRECISION for pdlahqr

COMPLEX for pclahqr

COMPLEX*16 for pzlahqr

Array. If *wantz* is .TRUE., on entry *z* must contain the current matrix *Z* of transformations accumulated by pdhseqr. If *wantz* is .FALSE., *z* is not referenced.

descz (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix Z.

work (local)

REAL for pslahqr

DOUBLE PRECISION for pdlahqr

COMPLEX for pclahqr

COMPLEX*16 for pzlahqr

Workspace array with size *lwork*.

lwork (local) INTEGER. The size of *work*. *lwork* is assumed big enough so that *lwork*≥3*n + max(2*max(*lld_z*,*lld_a*) + 2**LOCq*(*n*), 7*ceil(*n*/*hbl*)/*lcm*(NPROW,NPCOL))).

If *lwork* = −1, then *work*(1) gets set to the above number and the code returns immediately.

iwork (global and local) INTEGER array of size *ilwork*. Not referenced and can be NULL pointer.

ilwork (local) INTEGER This holds some of the *iblk* integer arrays. Not referenced and can be NULL pointer.

Output Parameters

a On exit, if *wantt* is .TRUE., *A* is upper quasi-triangular in rows and columns *ilo*:*ihi*, with any 2-by-2 or larger diagonal blocks not yet in standard form. If *wantt* is .FALSE., the contents of *A* are unspecified on exit.

work(1) On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

wr, *wi* (global replicated output)

REAL for pslahqr

DOUBLE PRECISION for pdlahqr

Arrays of size *n* each. The real and imaginary parts, respectively, of the computed eigenvalues *ilo* to *ihi*are stored in the corresponding elements of *wr* and *wi*. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and (*i* +1)-th, with *wi*(*i*)> 0 and *wi*(*i*+1) < 0. If *wantt* is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *A*. *A* may be returned with larger diagonal blocks until the next release.

w (global replicated output)

COMPLEX for pclahqr

COMPLEX*16 for pzlahqr

	Array of size *n*. The computed eigenvalues *ilo* to *ihi* are stored in the corresponding elements of *w*. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *w*, say the *i*-th and (*i*+1)-th, with *w*(*i*)> 0 and *w*(*i*+1) < 0. If *wantt* is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *A*. *A* may be returned with larger diagonal blocks until the next release.
z	On exit *z* has been updated; transformations are applied only to the submatrix *Z*(*iloz*:*ihiz*, *ilo*:*ihi*).
info	(global) INTEGER. = 0: the execution is successful. < 0: the parameter number - *info* is incorrect or inconsistent > 0: p?lahqr failed to compute all the eigenvalues *ilo* to *ihi* in a total of 30*(*ihi*–*ilo*+1) iterations; if *info* = *i*, elements *i*+1: *ihi* of *wr* and *wi* contain the eigenvalues that have been successfully computed.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?hseqr

Computes eigenvalues and (optionally) the Schur factorization of a matrix reduced to Hessenberg form.

Syntax

```
call pshseqr( job, compz, n, ilo, ihi, h, desch, wr, wi, z, descz, work, lwork, iwork, liwork, info )
```

```
call pdhseqr( job, compz, n, ilo, ihi, h, desch, wr, wi, z, descz, work, lwork, iwork, liwork, info )
```

Include Files

Description

p?hseqr computes the eigenvalues of an upper Hessenberg matrix *H* and, optionally, the matrices *T* and *Z* from the Schur decomposition $H = Z*T*Z^T$, where *T* is an upper quasi-triangular matrix (the Schur form), and *Z* is the orthogonal matrix of Schur vectors.

Optionally *Z* may be postmultiplied into an input orthogonal matrix *Q* so that this routine can give the Schur factorization of a matrix *A* which has been reduced to the Hessenberg form *H* by the orthogonal matrix *Q*: $A = Q*H*Q^T = (QZ)*T*(QZ)^T$.

NOTE

These restrictions apply to the use of p?hseqr:

- The code requires the distributed block size to be square and at least 6.
- The code requires A and Z to be distributed identically and have identical contexts.
- The matrix A must be in upper Hessenberg form. If elements below the subdiagonal are non-zero, the resulting transformations can be nonsimilar.
- All eigenvalues are distributed to all the nodes.

Input Parameters

job

(global) CHARACTER*1

= 'E': compute eigenvalues only;

= 'S': compute eigenvalues and the Schur form T.

compz

(global) CHARACTER*1

= 'N': no Schur vectors are computed;

= 'I': *z* is initialized to the unit matrix and the matrix *Z* of Schur vectors of *H* is returned;

= 'V': *z* must contain an orthogonal matrix *Q* on entry, and the product *Q***Z* is returned.

n

(global) INTEGER

The order of the Hessenberg matrix *H*. $n \geq 0$.

ilo, *ihi*

(global) INTEGER

It is assumed that *H* is already upper triangular in rows and columns 1:*ilo*-1 and *ihi*+1:*n*. *ilo* and *ihi* are normally set by a previous call to p gebal, and then passed to p?gehrd when the matrix output by p?gebal is reduced to Hessenberg form. Otherwise *ilo* and *ihi* should be set to 1 and *n* respectively. If $n>0$, then $1 \leq ilo \leq ihi \leq n$.

If $n = 0$, then *ilo* = 1 and *ihi* = 0.

h

REAL for pshseqr

DOUBLE PRECISION for pdhseqr

(global) array of size (*desch*(*lld_*),$LOC_c(n)$)

The upper Hessenberg matrix *H*.

desch

(global and local) INTEGER array of size *dlen_*

The array descriptor for the distributed matrix *H*.

z

REAL for pshseqr

DOUBLE PRECISION for pdhseqr

(global) array

If *compz* = 'V', on entry *z* must contain the current matrix *Z* of accumulated transformations from, for example, p?gehrd.

If *compz* = 'I', on entry *z* need not be set.

descz

(global and local) INTEGER array of size *dlen_*

The array descriptor for the distributed matrix *z*.

work

REAL for pshseqr

DOUBLE PRECISION for pdhseqr

(local workspace) array of size *lwork*.

lwork

(local) INTEGER

The length of the workspace array *work*.

If *lwork* = -1, then *work*(1) gets set to the above number and the code returns immediately.

iwork (local workspace) INTEGER array of size *liwork*

liwork (local) INTEGER

The length of the workspace array *iwork*.

If *liwork*=-1, then *iwork*(1) is set to -1 and the code returns immediately.

OUTPUT Parameters

h If *job* = 'S', *H* is upper quasi-triangular in rows and columns *ilo*:*ihi*, with 1-by-1 and 2-by-2 blocks on the main diagonal. The 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with *h*(*i*,*i*) = *h*(*i*+1,*i*+1) and *h*(*i*+1,*i*)**h*(*i*,*i*+1)<0. If *info* = 0 and *job* = 'E', the contents of *h* are unspecified on exit.

wr, *wi* REAL for pshseqr

DOUBLE PRECISION for pdhseqr

(global) array of size *n*

The real and imaginary parts, respectively, of the computed eigenvalues *ilo* to *ihi* are stored in the corresponding elements of *wr* and *wi*. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and (*i*+1)th, with *wi*(*i*)> 0 and *wi*(*i*+1) < 0. If *job* = 'S', the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*.

z REAL for pshseqr

DOUBLE PRECISION for pdhseqr

(global) array

z is updated; transformations are applied only to the submatrix *z*(*ilo*:*ihi*,*ilo*:*ihi*).

If *compz* = 'N', *z* is not referenced.

If *compz* = 'I' and *info* = 0, *z* contains the orthogonal matrix *Z* of the Schur vectors of *H*.

info INTEGER

= 0: successful exit

< 0: if *info* = -*i*, the *i*-th argument had an illegal value (see also below for -7777 and -8888).

> 0: if *info* = *i*, p?hseqr failed to compute all of the eigenvalues. Elements 1:*ilo*-1 and *i*+1:*n* of *wr* and *wi* contain those eigenvalues which have been successfully computed. (Failures are rare.)

If *info* > 0 and *job* = 'E', then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns *ilo* through *info* of the final, output value of *H*.

If *info* > 0 and *job* = 'S', then on exit (*) (initial value of *H*)*U = *U*(final value of *H*) where *U* is an orthogonal matrix. The final value of *H* is upper Hessenberg and quasi-triangular in rows and columns *info*+1 through *ihi*.

If *info* > 0 and *compz* = 'V', then on exit (final value of *Z*) = (initial value of *Z*)*U where *U* is the orthogonal matrix in (*) (regardless of the value of *job*.)

If *info* > 0 and *compz* = 'I', then on exit (final value of *Z*) = *U* where *U* is the orthogonal matrix in (*) (regardless of the value of *job*.)

If *info* > 0 and *compz* = 'N', then *z* is not accessed.

= -7777: p laqr0 failed to converge and p laqr1 was called instead.

= -8888: p?laqr1 failed to converge and p?laqr0 was called instead.

p?trevc

Computes right and/or left eigenvectors of a complex upper triangular matrix in parallel.

Syntax

```
call pctrevc (side, howmny, select, n, t, desct, vl, descvl, vr, descvr, mm, m, work, rwork, info )
call pztrevc (side, howmny, select, n, t, desct, vl, descvl, vr, descvr, mm, m, work, rwork, info )
call pdtrevc (side, howmny, select, n, t, desct, vl, descvl, vr, descvr, mm, m, work, info )
call pstrevc (side, howmny, select, n, t, desct, vl, descvl, vr, descvr, mm, m, work, info )
```

Description

p?trevc computes some or all of the right and/or left eigenvectors of a complex upper triangular matrix *T* in parallel.

The right eigenvector x and the left eigenvector y of *T* corresponding to an eigenvalue w are defined by:

*T*x = w*x,

y'**T* = w*y'

where y' denotes the conjugate transpose of the vector y.

If all eigenvectors are requested, the routine may either return the matrices *X* and/or *Y* of right or left eigenvectors of *T*, or the products *Q*X* and/or *Q*Y*, where *Q* is an input unitary matrix. If *T* was obtained from the Schur factorization of an original matrix *A* = *Q*T*Q', then *Q*X* and *Q*Y* are the matrices of right or left eigenvectors of *A*.

Input Parameters

side (global)

CHARACTER*1.

= 'R': compute right eigenvectors only;

= 'L': compute left eigenvectors only;

= 'B': compute both right and left eigenvectors.

howmny (global)

CHARACTER*1.

= 'A': compute all right and/or left eigenvectors;

= 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in *vr* and/or *vl*;

= 'S': compute selected right and/or left eigenvectors, specified by the logical array *select*.

select (global)

LOGICAL.

Array, size (*n*)

If *howmny* = 'S', *select* specifies the eigenvectors to be computed.

If *howmny* = 'A' or 'B', *select* is not referenced. To select the eigenvector corresponding to the *j*-th eigenvalue, *select*(*j*) must be set to .TRUE..

n (global)

INTEGER.

The order of the matrix *T*. *n* >= 0.

t (local)

COMPLEX for pctrevc

DOUBLE COMPLEX for pztrevc

DOUBLE PRECISION for pdtrevc

REAL for pstrevc

Array, size (*lld_t*,*LOCc*(*n*)).

The upper triangular matrix *T*. *T* is modified, but restored on exit.

desct (global and local)

INTEGER.

Array of size *dlen_*.

The array descriptor for the distributed matrix *T*.

vl (local)

COMPLEX for pctrevc

DOUBLE COMPLEX for pztrevc

DOUBLE PRECISION for pdtrevc

REAL for pstrevc

Array, size (*descvl*(*lld_*),*mm*)

On entry, if *side* = 'L' or 'B' and *howmny* = 'B', *vl* must contain an *n*-by-*n* matrix *Q* (usually the unitary matrix *Q* of Schur vectors returned by ?hseqr).

descvl

(global and local)

INTEGER.

Array of size *dlen_*.

The array descriptor for the distributed matrix *VL*.

vr

(local)

COMPLEX for pctrevc

DOUBLE COMPLEX for pztrevc

DOUBLE PRECISION for pdtrevc

REAL for pstrevc

Array, size (*descvr*(*lld_*),*mm*).

On entry, if *side* = 'R' or 'B' and *howmny* = 'B', *vr* must contain an *n*-by-*n* matrix *Q* (usually the unitary matrix *Q* of Schur vectors returned by ?hseqr).

descvr

(global and local)

INTEGER.

Array of size *dlen_*.

The array descriptor for the distributed matrix *VR*.

mm

(global)

INTEGER.

The number of columns in the arrays *vl* and/or *vr*. *mm* >= *m*.

work

(local)

COMPLEX for pctrevc

DOUBLE COMPLEX for pztrevc

DOUBLE PRECISION for pdtrevc

REAL for pstrevc

Array, size (2**desct*(*lld_*))

Additional workspace may be required if p?lattrs is updated to use *work*.

rwork

REAL for pctrevc

DOUBLE PRECISION for pztrevc

Array, size (*desct*(*lld_*))

Output Parameters

t

The upper triangular matrix *T*. *T* is modified, but restored on exit.

vl

On exit, if *side* = 'L' or 'B', *vl* contains:

if *howmny* = 'A', the matrix *Y* of left eigenvectors of *T*;

if *howmny* = 'B', the matrix *Q***Y*;

if *howmny* = 'S', the left eigenvectors of *T* specified by *select*, stored consecutively in the columns of *vl*, in the same order as their eigenvalues. If *side* = 'R', *vl* is not referenced.

vr

On exit, if *side* = 'R' or 'B', *vr* contains:

if *howmny* = 'A', the matrix *X* of right eigenvectors of *T*;

if *howmny* = 'B', the matrix *Q***X*;

if *howmny* = 'S', the right eigenvectors of *T* specified by *select*, stored consecutively in the columns of *vr*, in the same order as their eigenvalues. If *side* = 'L', *vr* is not referenced.

m

(global)

INTEGER.

The number of columns in the arrays *vl* and/or *vr* actually used to store the eigenvectors. If *howmny* = 'A' or 'B', *m* is set to *n*. Each selected eigenvector occupies one column.

info

(global)

INTEGER.

= 0: successful exit

< 0: if *info* = -i, the i-th argument had an illegal value

Application Notes

The algorithm used in this program is basically backward (forward) substitution. Scaling should be used to make the code robust against possible overflow. But scaling has not yet been implemented in p?lattrs which is called by this routine to solve the triangular systems. p?lattrs just calls p?trsv.

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be |x| + |y|.

Singular Value Decomposition: ScaLAPACK Driver Routines

This section describes ScaLAPACK routines for computing the singular value decomposition (SVD) of a general *m*-by-*n* matrix *A* (see LAPACK"Singular Value Decomposition").

To find the SVD of a general matrix *A*, this matrix is first reduced to a bidiagonal matrix *B* by a unitary (orthogonal) transformation, and then SVD of the bidiagonal matrix is computed. Note that the SVD of *B* is computed using the LAPACK routine ?bdsqr .

Table "Computational Routines for Singular Value Decomposition (SVD)" lists ScaLAPACK computational routines for performing this decomposition.

Computational Routines for Singular Value Decomposition (SVD)

Operation	General matrix	Orthogonal/unitary matrix
Reduce *A* to a bidiagonal matrix	p?gebrd	
Multiply matrix after reduction		p?ormbr/p?unmbr

p?gebrd

Reduces a general matrix to bidiagonal form.

Syntax

```
call psgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pdgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pcgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pzgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
```

Include Files

Description

The p?gebrd routine reduces a real/complex general *m*-by-*n* distributed matrix sub(*A*)= *A*(*ia*:*ia*+*m*-1, *ja*:*ja* +*n*-1) to upper or lower bidiagonal form *B* by an orthogonal/unitary transformation:

Q'*sub(*A*)**P* = *B*.

If *m*≥ *n*, *B* is upper bidiagonal; if *m* < *n*, *B* is lower bidiagonal.

Input Parameters

m

(global) INTEGER. The number of rows in the distributed matrix sub(*A*) (*m*≥0).

n

(global) INTEGER. The number of columns in the distributed matrix sub(*A*) (*n*≥0).

a

(local)

REAL for psgebrd

DOUBLE PRECISION for pdgebrd

COMPLEX for pcgebrd

DOUBLE COMPLEX for pzgebrd.

Real pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja* +*n*-1)). On entry, this array contains the distributed matrix sub (*A*).

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

work

(local)

REAL for psgebrd

DOUBLE PRECISION for pdgebrd

COMPLEX for pcgebrd

DOUBLE COMPLEX for pzgebrd.

Workspace array of size *lwork*.

lwork

(local or global) INTEGER, size of *work*, must be at least:

lwork≥*nb**(*mpa*0 + nqa0+1)+ *nqa*0

where *nb* = *mb_a* = *nb_a*,

```
iroffa = mod(ia-1, nb),
icoffa = mod(ja-1, nb),
iarow = indxg2p(ia, nb, MYROW, rsrc_a, NPROW),
iacol = indxg2p (ja, nb, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m +iroffa, nb, MYROW, iarow, NPROW),
nqa0 = numroc(n +icoffa, nb, MYCOL, iacol, NPCOL),
```

NOTE
`mod(x,y)` is the integer remainder of x/y.

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a

On exit, if $m \geq n$, the diagonal and the first superdiagonal of sub(*A*) are overwritten with the upper bidiagonal matrix *B*; the elements below the diagonal, with the array *tauq*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors, and the elements above the first superdiagonal, with the array *taup*, represent the orthogonal matrix *P* as a product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix *B*; the elements below the first subdiagonal, with the array *tauq*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors, and the elements above the diagonal, with the array *taup*, represent the orthogonal matrix *P* as a product of elementary reflectors. See *Application Notes* below.

d

(local)

`REAL` for single-precision flavors

`DOUBLE PRECISION` for double-precision flavors.

Array of size *LOCc*(*ja*+min(*m*,*n*)-1) if $m \geq n$ and *LOCr*(*ia*+min(*m*,*n*)-1) otherwise. The distributed diagonal elements of the bidiagonal matrix *B*: *d*(*i*) = *a*(*i*,*i*).

d is tied to the distributed matrix *A*.

e

(local)

`REAL` for single-precision flavors

`DOUBLE PRECISION` for double-precision flavors.

Array of size *LOCr*(*ia*+min(*m*,*n*)-1) if $m \geq n$; *LOCc*(*ja*+min(*m*,*n*)-2) otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix *B*:

	If `m≥n`, `e(i) = a(i,i+1)` for `i = 1,2,..., n-1`; if `m < n`, `e(i) = a(i+1,i)` for `i = 1,2,..., m-1`. `e` is tied to the distributed matrix *A*.

tauq, *taup*	(local)
	`REAL` for `psgebrd`
	`DOUBLE PRECISION` for `pdgebrd`
	`COMPLEX` for `pcgebrd`
	`DOUBLE COMPLEX` for `pzgebrd`.
	Arrays of size *LOCc*(*ja*+min(*m*,*n*)-1) for *tauq* and *LOCr*(*ia*+min(*m*,*n*)-1) for *taup*. Contain the scalar factors of the elementary reflectors that represent the orthogonal/unitary matrices *Q* and *P*, respectively. *tauq* and *taup* are tied to the distributed matrix *A*. See *Application Notes* below.

work(1)	On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.
info	(global) `INTEGER`. `= 0`: the execution is successful. `< 0`: if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrices *Q* and *P* are represented as products of elementary reflectors:

If `m≥n`,

Q = *H*(1)**H*(2)*...**H*(*n*), and *P* = *G*(1)**G*(2)*...**G*(*n*-1).

Each *H*(*i*) and *G*(*i*) has the form:

H(*i*)= *i* - *tauq* * *v* * *v'* and *G*(*i*) = *i* - *taup***u***u'*

where *tauq* and *taup* are real/complex scalars, and *v* and *u* are real/complex vectors;

v(1:*i*-1) = 0, *v*(*i*) = 1, and *v*(*i*+1:*m*) is stored on exit in *A*(*ia*+*i*:*ia*+*m*-1,*ja*+*i*-1);

u(1:*i*) = 0, *u*(*i*+1) = 1, and *u*(*i*+2:*n*) is stored on exit in *A* (*ia*+*i*-1,*ja*+*i*+1:*ja*+*n*-1);

tauq is stored in *tauq*(*ja*+*i*-1) and *taup* in *taup*(*ia*+*i*-1).

If *m* < *n*,

Q = *H*(1)**H*(2)*...**H*(*m*-1), and *P* = *G*(1)* *G*(2)*...* *G*(*m*)

Each *H* (*i*) and *G*(*i*) has the form:

H(*i*)= *i*-*tauq***v***v'* and *G*(*i*)= *i*-*taup***u***u'*

here *tauq* and *taup* are real/complex scalars, and *v* and *u* are real/complex vectors;

v(1:*i*) = 0, *v*(*i*+1) = 1, and *v*(*i*+2:*m*) is stored on exit in *A* (*ia*+*i*:*ia*+*m*-1,*ja*+*i*-1); *u*(1:*i*-1) = 0, *u*(*i*) = 1, and *u*(*i*+1:*n*) is stored on exit in *A*(*ia*+*i*-1,*ja*+*i*+1:*ja*+*n*-1);

tauq is stored in *tauq*(*ja*+*i*-1) and *taup* in *taup*(*ia*+*i*-1).

The contents of sub(*A*) on exit are illustrated by the following examples:

$m = 6$ and $n = 5$ ($m > n$):

$$\begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}$$

$m = 5$ and $n = 6$ ($m < n$):

$$\begin{bmatrix} d & u1 & u1 & u1 & u1 & u1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}$$

where *d* and *e* denote diagonal and off-diagonal elements of *B*, *vi* denotes an element of the vector defining *H*(*i*), and *ui* an element of the vector defining *G*(*i*).

p?ormbr

Multiplies a general matrix by one of the orthogonal matrices from a reduction to bidiagonal form determined by `p?gebrd`.

Syntax

```
call psormbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work, lwork, info)
```

```
call pdormbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work, lwork, info)
```

Include Files

Description

If *vect* = 'Q', the `p?ormbr` routine overwrites the general real distributed m-by-n matrix sub(*C*) = *C*(ic:ic +m-1,jc:jc+n-1) with

	side ='L'	*side* ='R'
trans = 'N':	*Q* sub(*C*)	sub(*C*) *Q*
trans = 'T':	Q^T sub(*C*)	sub(*C*) Q^T

If $vect$ = 'P', the routine overwrites sub(*C*) with

	side ='L'	*side* ='R'
trans = 'N':	*P* sub(*C*)	sub(*C*) *P*
trans = 'T':	P^T sub(*C*)	sub(*C*) P^T

Here *Q* and P^T are the orthogonal distributed matrices determined by p?gebrd when reducing a real distributed matrix *A*(*ia*:*, *ja*:*) to bidiagonal form: *A*(*ia*:*, *ja*:*) = *Q***B***P*^{T}. *Q* and P^T are defined as products of elementary reflectors *H*(*i*) and *G*(*i*) respectively.

Let *nq* = *m* if *side* = 'L' and *nq* = *n* if *side* = 'R'. Therefore *nq* is the order of the orthogonal matrix *Q* or P^T that is applied.

If *vect* = 'Q', *A*(*ia*:*, *ja*:*) is assumed to have been an *nq*-by-*k* matrix:

If *nq* ≥ *k*, *Q* = *H*(1) *H*(2)...*H*(*k*);

If *nq* < *k*, *Q* = *H*(1) *H*(2)...*H*(*nq*-1).

If *vect* = 'P', *A*(*ia*:*, *ja*:*) is assumed to have been a *k*-by-*nq* matrix:

If *k* < *nq*, *P* = *G*(1) *G*(2)...*G*(*k*);

If *k* ≥ *nq*, *P* = *G*(1) *G*(2)...*G*(*nq*-1).

Input Parameters

vect
(global) CHARACTER.
If *vect* ='Q', then *Q* or Q^T is applied.
If *vect* ='P', then *P* or P^T is applied.

side
(global) CHARACTER.
If *side* ='L', then *Q* or Q^T, *P* or P^T is applied from the left.
If *side* ='R', then *Q* or Q^T, *P* or P^T is applied from the right.

trans
(global) CHARACTER.
If *trans* = 'N', no transpose, *Q* or *P* is applied.
If *trans* = 'T', then Q^T or P^T is applied.

m
(global) INTEGER. The number of rows in the distributed matrix sub (*C*).

n
(global) INTEGER. The number of columns in the distributed matrix sub (*C*).

k
(global) INTEGER.
If *vect* = 'Q', the number of columns in the original distributed matrix reduced by p?gebrd;
If *vect* = 'P', the number of rows in the original distributed matrix reduced by p?gebrd.
Constraints: *k*≥ 0.

a
(local)
REAL for psormbr
DOUBLE PRECISION for pdormbr.

Pointer into the local memory to an array of size (*lld_a*,*LOCc*(*ja*+min(*nq*,*k*)-1)) if *vect*='Q', and (*lld_a*,*LOCc*(*ja*+*nq*-1)) if *vect* = 'P'.

nq = *m* if *side* = 'L', and *nq* = *n* otherwise.

The vectors that define the elementary reflectors *H*(*i*) and *G*(*i*), whose products determine the matrices *Q* and *P*, as returned by p?gebrd.

If *vect* = 'Q', *lld_a*≥max(1, *LOCr*(*ia*+*nq*-1));

If *vect* = 'P', *lld_a*≥max(1, *LOCr*(*ia*+min(*nq*, *k*)-1)).

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

tau

(local)

REAL for psormbr

DOUBLE PRECISION for pdormbr.

Array of size *LOCc*(*ja*+min(*nq*, *k*)-1), if *vect* = 'Q', and *LOCr*(*ia*+min(*nq*, *k*)-1), if *vect* = 'P'.

tau(*i*) must contain the scalar factor of the elementary reflector *H*(*i*) or *G*(*i*)

which determines *Q* or *P*, as returned by pdgebrd in its array argument *tauq* or *taup*. *tau* is tied to the distributed matrix *A*.

c

(local) REAL for psormbr

DOUBLE PRECISION for pdormbr

Pointer into the local memory to an array of size (*lld_c*,*LOCc*(*jc*+*n*-1)).

Contains the local pieces of the distributed matrix sub (*C*).

ic, *jc*

(global) INTEGER. The row and column indices in the global matrix *C* indicating the first row and the first column of the submatrix *C*, respectively.

descc

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work

(local)

REAL for psormbr

DOUBLE PRECISION for pdormbr.

Workspace array of size *lwork*.

lwork

(local or global) INTEGER, size of *work*, must be at least:

If *side* = 'L'

nq = *m*;

if ((*vect* = 'Q' and *nq*≥*k*) or (*vect* is not equal to 'Q' and *nq*>*k*)), *iaa*=*ia*; *jaa*=*ja*; *mi*=*m*; *ni*=*n*; *icc*=*ic*; *jcc*=*jc*;

else

iaa= *ia*+1; *jaa*=*ja*; *mi*=*m*-1; *ni*=*n*; *icc*=*ic*+1; *jcc*= *jc*;

end if

else

If *side* = 'R', *nq* = *n*;

if((*vect* = 'Q' and *nq*≥*k*) or (*vect* is not equal to 'Q' and *nq*>*k*)),

iaa=*ia*; *jaa*=*ja*; *mi*=*m*; *ni*=*n*; *icc*=*ic*; *jcc*=*jc*;

else

iaa= *ia*; *jaa*= *ja*+1; *mi*= *m*; *ni*= *n*-1; *icc*= *ic*; *jcc*= *jc*+1;

end if

end if

If *vect* = 'Q',

If *side* = 'L', *lwork*≥max((*nb_a**(*nb_a*-1))/2, (*nqc*0 + *mpc*0)**nb_a*) + *nb_a* * *nb_a*

else if *side* = 'R',

lwork≥max((*nb_a**(*nb_a*-1))/2, (*nqc*0 + max(*npa*0 + numroc(numroc(*ni*+*icoffc*, *nb_a*, 0, 0, NPCOL), *nb_a*, 0, 0, *lcmq*), *mpc*0))**nb_a*) + *nb_a***nb_a*

end if

else if *vect* is not equal to 'Q', if *side* = 'L',

lwork≥max((*mb_a**(*mb_a*-1))/2, (*mpc*0 + max(*mqa*0 + numroc(numroc(*mi*+iroffc, *mb_a*, 0, 0, NPROW), *mb_a*, 0, 0, *lcmp*), *nqc*0))**mb_a*) + *mb_a***mb_a*

else if *side* = 'R',

lwork≥max((*mb_a**(*mb_a*-1))/2, (*mpc*0 + *nqc*0)**mb_a*) + *mb_a***mb_a*

end if

end if

where *lcmp* = *lcm*/NPROW, *lcmq* = *lcm*/NPCOL, with *lcm* = ilcm(NPROW, NPCOL),

iroffa = mod(*iaa*-1, *mb_a*),

icoffa = mod(*jaa*-1, *nb_a*),

iarow = indxg2p(*iaa*, *mb_a*, MYROW, *rsrc_a*, NPROW),

iacol = indxg2p(*jaa*, *nb_a*, MYCOL, *csrc_a*, NPCOL),

*mqa*0 = numroc(*mi*+*icoffa*, *nb_a*, MYCOL, *iacol*, NPCOL),

*npa*0 = numroc(*ni*+*iroffa*, *mb_a*, MYROW, *iarow*, NPROW),

iroffc = mod(*icc*-1, *mb_c*),

icoffc = mod(*jcc*-1, *nb_c*),

icrow = indxg2p(*icc*, *mb_c*, MYROW, *rsrc_c*, NPROW),

iccol = indxg2p(*jcc*, *nb_c*, MYCOL, *csrc_c*, NPCOL),

*mpc*0 = numroc(*mi*+*iroffc*, *mb_c*, MYROW, *icrow*, NPROW),

*nqc*0 = numroc(*ni*+*icoffc*, *nb_c*, MYCOL, *iccol*, NPCOL),

NOTE
mod(*x*,*y*) is the integer remainder of *x*/*y*.

indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c — On exit, if *vect*='Q', sub(*C*) is overwritten by *Q**sub(*C*), or *Q*'*sub(*C*), or sub(*C*)**Q*', or sub(*C*)**Q*; if *vect*='P', sub(*C*) is overwritten by *P**sub(*C*), or *P*'*sub(*C*), or sub(*C*)**P*, or sub(*C*)**P*'.

work(1) — On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

info — (global) INTEGER.

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?unmbr

Multiplies a general matrix by one of the unitary transformation matrices from a reduction to bidiagonal form determined by p?gebrd.

Syntax

call pcunmbr(*vect*, *side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pzunmbr(*vect*, *side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

Include Files

Description

If *vect* = 'Q', the p?unmbr routine overwrites the general complex distributed *m*-by-*n* matrix sub(*C*) = *C*(*ic*:*ic*+*m*-1,*jc*:*jc*+*n*-1) with

	side ='L'	*side* ='R'
trans = 'N':	*Q**sub(*C*)	sub(*C*)**Q*
trans = 'C':	Q^H*sub(*C*)	sub(*C*)*Q^H

If *vect* = 'P', the routine overwrites sub(*C*) with

	side ='L'	*side* ='R'
trans = 'N':	*P**sub(*C*)	sub(*C*)**P*
trans = 'C':	P^H*sub(*C*)	sub(*C*)*P^H

Here *Q* and P^H are the unitary distributed matrices determined by p?gebrd when reducing a complex distributed matrix *A*(*ia*:*, *ja*:*) to bidiagonal form: *A*(*ia*:*, *ja*:*) = *Q***B**P^H.

Q and P^H are defined as products of elementary reflectors *H*(*i*) and *G*(*i*) respectively.

Let *nq* = *m* if *side* = 'L' and *nq* = *n* if *side* = 'R'. Therefore *nq* is the order of the unitary matrix *Q* or P^H that is applied.

If *vect* = 'Q', *A*(*ia*:*, *ja*:*) is assumed to have been an *nq*-by-*k* matrix:

If *nq* ≥ *k*, *Q* = *H*(1) *H*(2)... *H*(*k*);

If *nq* < *k*, *Q* = *H*(1) *H*(2)... *H*(*nq*-1).

If *vect* = 'P', *A*(*ia*:*, *ja*:*) is assumed to have been a *k*-by-*nq* matrix:

If *k* < *nq*, *P* = *G*(1) *G*(2)... *G*(*k*);

If *k* ≥ *nq*, *P* = *G*(1) *G*(2)... *G*(*nq*-1).

Input Parameters

vect
(global) CHARACTER.
If *vect* ='Q', then *Q* or Q^H is applied.
If *vect* ='P', then *P* or P^H is applied.

side
(global) CHARACTER.
If *side* ='L', then *Q* or Q^H, *P* or P^H is applied from the left.
If *side* ='R', then *Q* or Q^H, *P* or P^H is applied from the right.

trans
(global) CHARACTER.
If *trans* = 'N', no transpose, *Q* or *P* is applied.
If *trans* = 'C', conjugate transpose, Q^H or P^H is applied.

m
(global) INTEGER. The number of rows in the distributed matrix sub (*C*) *m*≥0.

n
(global) INTEGER. The number of columns in the distributed matrix sub (*C*) *n*≥0.

k
(global) INTEGER.
If *vect* = 'Q', the number of columns in the original distributed matrix reduced by p?gebrd;
If *vect* = 'P', the number of rows in the original distributed matrix reduced by p?gebrd.

Constraints: $k \geq 0$.

a (local)

COMPLEX for psormbr

DOUBLE COMPLEX for pdormbr.

Pointer into the local memory to an array of size (*lld_a*,*LOCc*(*ja*+min(*nq*,*k*)-1)) if *vect*='Q', and (*lld_a*,*LOCc*(*ja*+*nq*-1)) if *vect* = 'P'.

nq = *m* if *side* = 'L', and *nq* = *n* otherwise.

The vectors that define the elementary reflectors *H*(*i*) and *G*(*i*), whose products determine the matrices *Q* and *P*, as returned by p?gebrd.

If *vect* = 'Q', *lld_a* ≥ max(1, *LOCr*(*ia*+*nq*-1));

If *vect* = 'P', *lld_a* ≥ max(1, *LOCr*(*ia*+min(*nq*, *k*)-1)).

ia, *ja* (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

tau (local)

COMPLEX for pcunmbr

DOUBLE COMPLEX for pzunmbr.

Array of size *LOCc*(*ja*+min(*nq*, *k*)-1), if *vect* = 'Q', and *LOCr*(*ia*+min(*nq*, *k*)-1), if *vect* = 'P'.

tau(*i*) must contain the scalar factor of the elementary reflector *H*(*i*) or *G*(*i*), which determines *Q* or *P*, as returned by p?gebrd in its array argument *tauq* or *taup*. *tau* is tied to the distributed matrix *A*.

c (local) COMPLEX for pcunmbr

DOUBLE COMPLEX for pzunmbr

Pointer into the local memory to an array of size (*lld_c*,*LOCc*(*jc*+*n*-1)).

Contains the local pieces of the distributed matrix sub (*C*).

ic, *jc* (global) INTEGER. The row and column indices in the global matrix *C* indicating the first row and the first column of the submatrix *C*, respectively.

descc (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work (local)

COMPLEX for pcunmbr

DOUBLE COMPLEX for pzunmbr.

Workspace array of size *lwork*.

lwork (local or global) INTEGER, size of *work*, must be at least:

If *side* = 'L'

nq = *m*;

if ((*vect* = 'Q' and *nq* ≥ *k*) or (*vect* is not equal to 'Q' and *nq*>*k*)), *iaa*= *ia*; *jaa*= *ja*; *mi*= *m*; *ni*= *n*; *icc*= *ic*; *jcc*= *jc*;

else

iaa= *ia*+1; *jaa*= *ja*; *mi*= *m*-1; *ni*= *n*; *icc*= *ic*+1; *jcc*= *jc*;

end if

else

If *side* = 'R', *nq* = *n*;

if ((*vect* = 'Q' and *nq* ≥ *k*) or (*vect* is not equal to 'Q' and *nq*≥*k*)),

iaa= *ia*; *jaa*= *ja*; *mi*= *m*; *ni*= *n*; *icc*= *ic*; *jcc*= *jc*;

else

iaa= *ia*; *jaa*= *ja*+1; *mi*= *m*; *ni*= *n*-1; *icc*= *ic*; *jcc*= *jc*+1;

end if

end if

If *vect* = 'Q',

If *side* = 'L', *lwork* ≥ max((*nb_a**(*nb_a*-1))/2, (*nqc*0+*mpc*0)**nb_a*) + *nb_a***nb_a*

else if *side* = 'R',

lwork ≥ max((*nb_a**(*nb_a*-1))/2, (*nqc*0 + max(*npa*0+numroc(numroc(*ni*+*icoffc*, *nb_a*, 0, 0, NPCOL), *nb_a*, 0, 0, *lcmq*), *mpc*0))**nb_a*) + *nb_a***nb_a*

end if

else if *vect* is not equal to 'Q',

if *side* = 'L',

lwork ≥ max((*mb_a**(*mb_a*-1))/2, (*mpc*0 + max(*mqa*0+numroc(numroc(*mi*+iroffc, *mb_a*, 0, 0, NPROW), *mb_a*, 0, 0, *lcmp*), *nqc*0))**mb_a*) + *mb_a***mb_a*

else if *side* = 'R',

lwork ≥ max((*mb_a**(*mb_a*-1))/2, (*mpc*0 + *nqc*0)**mb_a*) + *mb_a***mb_a*

end if

end if

where *lcmp* = *lcm*/NPROW, *lcmq* = *lcm*/NPCOL, with *lcm* = ilcm(NPROW, NPCOL),

iroffa = mod(*iaa*-1, *mb_a*),

icoffa = mod(*jaa*-1, *nb_a*),

iarow = indxg2p(*iaa*, *mb_a*, MYROW, *rsrc_a*, NPROW),

iacol = indxg2p(*jaa*, *nb_a*, MYCOL, *csrc_a*, NPCOL),

*mqa*0 = numroc(*mi*+*icoffa*, *nb_a*, MYCOL, *iacol*, NPCOL),

*npa*0 = numroc(*ni*+*iroffa*, *mb_a*, MYROW, *iarow*, NPROW),

iroffc = mod(*icc*-1, *mb_c*),

icoffc = mod(*jcc*-1, *nb_c*),

icrow = indxg2p(*icc*, *mb_c*, MYROW, *rsrc_c*, NPROW),

iccol = indxg2p(*jcc*, *nb_c*, MYCOL, *csrc_c*, NPCOL),

*mpc*0 = numroc(*mi*+*iroffc*, *mb_c*, MYROW, *icrow*, NPROW),

*nqc*0 = numroc(*ni*+*icoffc*, *nb_c*, MYCOL, *iccol*, NPCOL),

NOTE
mod(*x*,*y*) is the integer remainder of *x*/*y*.

indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c — On exit, if *vect*='Q', sub(*C*) is overwritten by *Q**sub(*C*), or *Q*'*sub(*C*), or sub(*C*)**Q*', or sub(*C*)**Q*; if *vect*='P', sub(*C*) is overwritten by *P**sub(*C*), or *P*'*sub(*C*), or sub(*C*)**P,* or sub(*C*)**P*'.

work(1) — On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

info — (global) INTEGER.

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Generalized Symmetric-Definite Eigenvalue Problems: ScaLAPACK Computational Routines

This section describes ScaLAPACK routines that allow you to reduce the *generalized symmetric-definite eigenvalue problems* (see LAPACKGeneralized Symmetric-Definite Eigenvalue Problems) to standard symmetric eigenvalue problem $Cy = \lambda y$, which you can solve by calling ScaLAPACK routines (see Symmetric Eigenproblems).

Table "Computational Routines for Reducing Generalized Eigenproblems to Standard Problems" lists these routines.

Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

Operation	Real symmetric matrices	Complex Hermitian matrices
Reduce to standard problems	p?sygst	p?hegst

p?sygst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

Syntax

```
call pssygst(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale, info)
call pdsygst(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale, info)
```

Include Files

Description

The p?sygstroutine reduces real symmetric-definite generalized eigenproblems to the standard form.

In the following sub(*A*) denotes *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) and sub(*B*) denotes *B*(*ib*:*ib*+*n*-1, *jb*:*jb*+*n*-1).

If *ibtype* = 1, the problem is

sub(*A*)*x = λ*sub(*B*)*x,

and sub(*A*) is overwritten by inv(U^T)*sub(*A*)*inv(*U*), or inv(*L*)*sub(*A*)*inv(L^T).

If *ibtype* = 2 or 3, the problem is

sub(*A*)*sub(*B*)*x = λ*x, or sub(*B*)*sub(*A*)*x = λ*x,

and sub(*A*) is overwritten by *U*sub(*A*)*U^T, or L^T*sub(*A*)**L*.

sub(*B*) must have been previously factorized as U^T**U* or *L*L^T by p?potrf.

Input Parameters

ibtype — (global) INTEGER. Must be 1 or 2 or 3.

If *itype* = 1, compute inv(U^T)*sub(*A*)*inv(*U*), or inv(*L*)*sub(*A*)*inv(L^T);

If *itype* = 2 or 3, compute *U*sub(*A*)*U^T, or L^T*sub(*A*)**L*.

uplo — (global) CHARACTER. Must be 'U' or 'L'.

If *uplo* = 'U', the upper triangle of sub(*A*) is stored and sub (*B*) is factored as U^T**U*.

If *uplo* = 'L', the lower triangle of sub(*A*) is stored and sub (*B*) is factored as *L*L^T.

n — (global) INTEGER. The order of the matrices sub (*A*) and sub (*B*) (*n*≥ 0).

a — (local)

REAL for pssygst

DOUBLE PRECISION for pdsygst.

Pointer into the local memory to an array of size (*lld_a*,*LOCc*(*ja*+*n*-1)). On entry, the array contains the local pieces of the *n*-by-*n* symmetric distributed matrix sub(*A*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*A*) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

b

(local)

REAL for pssygst

DOUBLE PRECISION for pdsygst.

Pointer into the local memory to an array of size (*lld_b*,*LOCc*(*jb*+*n*-1)). On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of sub (*B*) as returned by p?potrf.

ib, *jb*

(global) INTEGER. The row and column indices in the global matrix *B* indicating the first row and the first column of the submatrix *B*, respectively.

descb

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix B.

Output Parameters

a

On exit, if *info* = 0, the transformed matrix, stored in the same format as sub(*A*).

scale

(global)

REAL for pssygst

DOUBLE PRECISION for pdsygst.

Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. At present, *scale* is always returned as 1.0, it is returned here to allow for future enhancement.

info

(global) INTEGER.

If *info* = 0, the execution is successful. If *info* < 0, if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?hegst

Reduces a Hermitian positive-definite generalized eigenvalue problem to the standard form.

Syntax

```
call pchegst(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale, info)
```

```
call pzhegst(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale, info)
```

Include Files

Description

The p?hegst routine reduces complex Hermitian positive-definite generalized eigenproblems to the standard form.

In the following sub(*A*) denotes *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) and sub(*B*) denotes *B*(*ib*:*ib*+*n*-1, *jb*:*jb*+*n*-1).

If *ibtype* = 1, the problem is

sub(*A*)*x* = λ*sub(*B*)*x*,

and sub(*A*) is overwritten by inv(U^H)*sub(*A*)*inv(*U*), or inv(*L*)*sub(*A*)*inv(L^H).

If *ibtype* = 2 or 3, the problem is

sub(*A*)*sub(*B*)*x* = λ**x*, or sub(*B*)*sub(*A*)*x* = λ**x*,

and sub(*A*) is overwritten by *U*sub(*A*)*U^H, or L^H*sub(*A*)**L*.

sub(*B*) must have been previously factorized as U^H**U* or *L*L^H by p?potrf.

Input Parameters

ibtype

(global) INTEGER. Must be 1 or 2 or 3.

If *itype* = 1, compute inv(U^H)*sub(*A*)*inv(*U*), or inv(*L*)*sub(*A*)*inv(L^H);

If *itype* = 2 or 3, compute *U*sub(*A*)*U^H, or L^H*sub(*A*)**L*.

uplo

(global) CHARACTER. Must be 'U' or 'L'.

If *uplo* = 'U', the upper triangle of sub(*A*) is stored and sub (*B*) is factored as U^H**U*.

If *uplo* = 'L', the lower triangle of sub(*A*) is stored and sub (*B*) is factored as *L*L^H.

n

(global) INTEGER. The order of the matrices sub (*A*) and sub (*B*) (*n*≥0).

a

(local)

COMPLEX for pchegst

DOUBLE COMPLEX for pzhegst.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)). On entry, the array contains the local pieces of the *n*-by-*n* Hermitian distributed matrix sub(*A*). If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*A*) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

b

(local)

COMPLEX for pchegst

DOUBLE COMPLEX for pzhegst.

Pointer into the local memory to an array of size (*lld_b*,*LOCc*(*jb*+*n*-1)). On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of sub (*B*) as returned by p?potrf.

ib, *jb* — (global) INTEGER. The row and column indices in the global matrix *B* indicating the first row and the first column of the submatrix *B*, respectively.

descb — (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix B.

Output Parameters

a — On exit, if *info* = 0, the transformed matrix, stored in the same format as sub(*A*).

scale — (global)

REAL for pchegst

DOUBLE PRECISION for pzhegst.

Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. At present, *scale* is always returned as 1.0, it is returned here to allow for future enhancement.

info — (global) INTEGER.

If *info* = 0, the execution is successful. If *info* <0, if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

ScaLAPACK Driver Routines

Table "ScaLAPACK Driver Routines" lists ScaLAPACK driver routines available for solving systems of linear equations, linear least-squares problems, standard eigenvalue and singular value problems, and generalized symmetric definite eigenproblems.

ScaLAPACK Driver Routines

Type of Problem	Matrix type, storage scheme	Driver
Linear equations	general (partial pivoting)	p?gesv (simple driver) / p?gesvx (expert driver)
	general band (partial pivoting)	p?gbsv (simple driver)
	general band (no pivoting)	p?dbsv (simple driver)
	general tridiagonal (no pivoting)	p?dtsv (simple driver)
	symmetric/Hermitian positive-definite	p?posv (simple driver) / p?posvx (expert driver)
	symmetric/Hermitian positive-definite, band	p?pbsv (simple driver)
	symmetric/Hermitian positive-definite, tridiagonal	p?ptsv (simple driver)
Linear least squares problem	general *m*-by-*n*	p?gels

Type of Problem	Matrix type, storage scheme	Driver
Non-symmetric eigenvalue problem	general	p?geevx (expert driver)
Symmetric eigenvalue problem	symmetric/Hermitian	p?syev / p?heev (simple driver); p?syevd / p?heevd (simple driver with a divide and conquer algorithm); p?syevx / p?heevx (expert driver); p?syevr / p?heevr (simple driver with MRRR algorithm)
Singular value decomposition	general *m*-by-*n*	p?gesvd
Generalized symmetric definite eigenvalue problem	symmetric/Hermitian, one matrix also positive-definite	p?sygvx / p?hegvx (expert driver)

p?geevx

Computes for an n-by-n real/complex non-symmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Syntax

```
call psgeevx(balanc, jobvl, jobvr, sense, n, a, desca, wr, wi, vl, descvl, vr, descvr, ilo, ihi, scale, abnrm, rconde, rcondv, work, lwork, info)
```

```
call pdgeevx(balanc, jobvl, jobvr, sense, n, a, desca, wr, wi, vl, descvl, vr, descvr, ilo, ihi, scale, abnrm, rconde, rcondv, work, lwork, info)
```

```
call pcgeevx(balanc, jobvl, jobvr, sense, n, a, desca, w, vl, descvl, vr, descvr, ilo, ihi, scale, abnrm, rconde, rcondv, work, lwork, info)
```

```
call pzgeevx(balanc, jobvl, jobvr, sense, n, a, desca, w, vl, descvl, vr, descvr, ilo, ihi, scale, abnrm, rconde, rcondv, work, lwork, info)
```

Include Files

Description

The p?geevx routine computes for an *n*-by-*n* real/complex non-symmetric matrix *A*, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (*ilo*, *ihi*, *scale*, and *abnrm*), reciprocal condition numbers for the eigenvalues (*rconde*).

The right eigenvector *v* of *A* satisfies

$$A \cdot v = \lambda \cdot v$$

where λ is its eigenvalue.

The left eigenvector *u* of *A* satisfies.

$u^H A = \lambda u^H$

where u^H denotes the conjugate transpose of *u*. The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation *D***A**inv(*D*), where *D* is a diagonal matrix, to make its rows and columns closer in norm and the condition number of its eigenvalues smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers in exact arithmetic, but diagonal scaling will.

NOTE
The current version doesn't support computation of the reciprocal condition numbers for the right eigenvectors.

Current Notes and Restrictions

All the `p?geevx` interfaces call `p?lahqr` for computing eigenvalues and eigenvectors of the Hessenberg matrices. There are several restrictions for the usage of `p?lahqr`, which include:

- The current implementation of `p?lahqr` requires the distributed block size to be square and at least six (6); unlike simpler codes like LU, this algorithm is extremely sensitive to block size.
- The current implementation of `p?lahqr` requires that input matrix *A*, the left and right eigenvector matrices *VR* and/or *VL* to be distributed identically and have identical context.

Parameters

balanc

(global). Must be 'N', 'P', 'S', or 'B'. Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues.

If *balanc* = 'N', do not diagonally scale or permute;

If *balanc* = 'P', perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale;

If *balanc* = 'S', diagonally scale the matrix, that is, replace *A* by *D***A**`inv`(*D*), where *D* is a diagonal matrix chosen to make the rows and columns of *A* more equal in norm. Do not permute;

If *balanc* = 'B', both diagonally scale and permute *A*.

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

jobvl

(global). Must be 'N' or 'V'.

If *jobvl* = 'N', left eigenvectors of *A* are not computed;

If *jobvl* = 'V', left eigenvectors of *A* are computed.

If *sense* = 'E', then *jobvl* must be 'V'.

jobvr

(global). Must be 'N' or 'V'.

If *jobvr* = 'N', right eigenvectors of *A* are not computed;

If *jobvr* = 'V', right eigenvectors of *A* are computed.

If *sense* = 'E', then *jobvr* must be 'V'.

sense

(global). Must be 'N' or 'E'. Determines which reciprocal condition numbers are computed.

If *sense* = 'N', none are computed.

If *sense* = 'E', computed for eigenvalues only.

n

(global) The order of the distributed matrix *A* ($n \geq 0$).

a

(local)

Pointer into the local memory to an array of size *lld_a*LOCc*(*n*). On entry, this array contains the local pieces of the *n*-by-*n* general distributed matrix *A* to be reduced.

desca (global and local) array of size dlen_. The array descriptor for the distributed matrix *A*.

wr, *wi* (global output) Arrays, size at least max (1, *n*) each. Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w (global output) Array, size at least max(1, *n*). Contains the computed eigenvalues.

vl (local output)

Pointer into the local memory to an array of size (DESCVL(LLD_),LOCc(n)).

If *jobvl* = 'N', *vl* is not referenced. If *jobvl* = 'V', the *vl* parameter contains the local pieces of the left eigenvectors of the matrix *A*.

descvl (global and local input) array of size *dlen_*. The array descriptor for the distributed matrix *vl*.

vr (local output)

Pointer into the local memory to an array of size (DESCVR(LLD_),LOCc(n)).

If *jobvr* = 'N', *vr* is not referenced. If *jobvr* = 'V', the *vr* parameter contains the local pieces of the right eigenvectors of the matrix *A*.

descvr (global and local input) array of size *dlen_*. The array descriptor for the distributed matrix *vr*.

ilo, *ihi* (global output)

ilo and *ihi* are integer values determined when *A* was balanced.

The balanced *A*(i,j) = 0 if i > j and j = 1,..., *ilo*-1 or i= *ihi*+1,..., *n*.

If *balanc* = 'N' or 'S', *ilo* = 1 and *ihi* = *n*.

scale (global output)

Array, size at least max(1, *n*). Details of the permutations and scaling factors applied when balancing *A*.

If P[*j* - 1] is the index of the row and column interchanged with row and column *j*, and D[*j* - 1] is the scaling factor applied to row and column *j*, then

scale[*j* - 1] = P[*j* - 1], for *j* = 1,...,*ilo*-1

= D[*j* - 1], for *j* = *ilo*,...,*ihi*

= P[*j* - 1] for *j* = *ihi*+1,..., *n*.

The order in which the interchanges are made is *n* to *ihi*+1, then 1 to *ilo*-1.

abnrm The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

rconde Array, size at least max(1, *n*).

rconde[*j* - 1] is the reciprocal condition number of the *j*-th eigenvalue.

rcondv	Not supported in the current version. It could be null pointer.
work	(local) Workspace array of size *lwork*.
lwork	(local or global) size of the array *work*. If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum size for the work array. These values are returned in the first entry of the *work* array, and no error message is issued by pxerbla.
info	(global) = 0: the execution is successful. < 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*- 1, had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?gesv

Computes the solution to the system of linear equations with a square distributed matrix and multiple right-hand sides.

Syntax

```
call psgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pdgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pcgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pzgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
```

Include Files

Description

The p?gesvroutine computes the solution to a real or complex system of linear equations sub(*A*)**X* = sub(*B*), where sub(*A*) = *A*(*ia:ia+n-1*, *ja:ja+n-1*) is an *n*-by-*n* distributed matrix and *X* and sub(*B*) = *B*(*ib:ib+n-1*, *jb:jb+nrhs-1*) are *n*-by-*nrhs* distributed matrices.

The *LU* decomposition with partial pivoting and row interchanges is used to factor sub(*A*) as sub(*A*) = *P***L***U*, where *P* is a permutation matrix, *L* is unit lower triangular, and *U* is upper triangular. *L* and *U* are stored in sub(*A*). The factored form of sub(*A*) is then used to solve the system of equations sub(*A*)**X* = sub(*B*).

Input Parameters

n	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix sub(*A*) (*n*≥ 0).
nrhs	(global) INTEGER. The number of right hand sides, that is, the number of columns of the distributed submatrices *B* and *X* (*nrhs*≥ 0).
a, *b*	(local) REAL for psgesv

DOUBLE PRECISION for pdgesv

COMPLEX for pcgesv

DOUBLE COMPLEX for pzgesv.

Pointers into the local memory to arrays of local size *a*(*lld_a*, *LOCc*(*ja*+*n*-1)) and *b*(*lld_b*, *LOCc*(*jb*+*nrhs*-1)), respectively.

On entry, the array *a* contains the local pieces of the *n*-by-*n* distributed matrix sub(*A*) to be factored.

On entry, the array *b* contains the right hand side distributed matrix sub(*B*).

ia, *ja* — (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of sub(*A*), respectively.

desca — (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

ib, *jb* — (global) INTEGER. The row and column indices in the global matrix *B* indicating the first row and the first column of sub(*B*), respectively.

descb — (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

Output Parameters

a — Overwritten by the factors *L* and *U* from the factorization sub(*A*) = *P***L***U*; the unit diagonal elements of *L* are not stored .

b — Overwritten by the solution distributed matrix *X*.

ipiv — (local) INTEGER Array of size *LOCr*(*m_a*)+*mb_a*. This array contains the pivoting information. The (local) row i of the matrix was interchanged with the (global) row *ipiv*(i).

This array is tied to the distributed matrix *A*.

info — (global) INTEGER. If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

info> 0:

If *info* = *k*, *U*(*ia*+*k*-1,*ja*+*k*-1) is exactly zero. The factorization has been completed, but the factor *U* is exactly singular, so the solution could not be computed.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?gesvx

Uses the LU factorization to compute the solution to the system of linear equations with a square matrix A and multiple right-hand sides, and provides error bounds on the solution.

Syntax

Include Files

Description

The p?gesvx routine uses the *LU* factorization to compute the solution to a real or complex system of linear equations *AX = B*, where *A* denotes the *n*-by-*n* submatrix *A(ia:ia+n-1, ja:ja+n-1)*, *B* denotes the *n*-by-*nrhs* submatrix *B(ib:ib+n-1, jb:jb+nrhs-1)* and *X* denotes the *n*-by-*nrhs* submatrix *X(ix:ix+n-1, jx:jx+nrhs-1)*.

Error bounds on the solution and a condition estimate are also provided.

In the following description, *af* stands for the subarray *af(iaf:iaf+n-1, jaf:jaf+n-1)*.

The routine p?gesvx performs the following steps:

1. If *fact* = 'E', real scaling factors *R* and *C* are computed to equilibrate the system:

   trans = 'N': diag(*R*)**A**diag(*C*) *diag(*C*)-1**X* = diag(*R*)*B

   trans = 'T': (diag(*R*)**A**diag(*C*))*T* *diag(*R*)-1**X* = diag(*C*)*B

   trans = 'C': (diag(*R*)**A**diag(*C*))*H* *diag(*R*)-1**X* = diag(*C*)*B

   Whether or not the system will be equilibrated depends on the scaling of the matrix *A*, but if equilibration is used, *A* is overwritten by diag(*R*)**A**diag(*C*) and *B* by diag(*R*)**B* (if *trans*='N') or diag(*c*)**B* (if *trans* = 'T' or 'C').
2. If *fact* = 'N' or 'E', the *LU* decomposition is used to factor the matrix *A* (after equilibration if *fact* = 'E') as *A* = *PLU*, where *P* is a permutation matrix, *L* is a unit lower triangular matrix, and *U* is upper triangular.
3. The factored form of *A* is used to estimate the condition number of the matrix *A*. If the reciprocal of the condition number is less than relative machine precision, steps 4 - 6 are skipped.
4. The system of equations is solved for *X* using the factored form of *A*.
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix *X* is premultiplied by diag(*C*) (if *trans* = 'N') or diag(*R*) (if *trans* = 'T' or 'C') so that it solves the original system before equilibration.

Input Parameters

fact (global) CHARACTER*1. Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix *A* is supplied on entry, and if not, whether the matrix *A* should be equilibrated before it is factored.

If *fact* = 'F' then, on entry, *af* and *ipiv* contain the factored form of *A*. If *equed* is not 'N', the matrix *A* has been equilibrated with scaling factors given by *r* and *c*. Arrays *a*, *af*, and *ipiv* are not modified.

If *fact* = 'N', the matrix *A* is copied to *af* and factored.

If *fact* = 'E', the matrix *A* is equilibrated if necessary, then copied to *af* and factored.

trans

(global) CHARACTER*1. Must be 'N', 'T', or 'C'.

Specifies the form of the system of equations:

If *trans* = 'N', the system has the form $A*X = B$ (No transpose);

If *trans* = 'T', the system has the form $A^T*X = B$ (Transpose);

If *trans* = 'C', the system has the form $A^H*X = B$ (Conjugate transpose);

n

(global) INTEGER. The number of linear equations; the order of the submatrix *A*(*n*≥ 0).

nrhs

(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrices *B* and *X*(*nrhs*≥ 0).

a, *af*, *b*, *work*

(local)

REAL for psgesvx

DOUBLE PRECISION for pdgesvx

COMPLEX for pcgesvx

DOUBLE COMPLEX for pzgesvx.

Pointers into the local memory to arrays of local size *a*(*lld_a*,*LOCc*(*ja*+*n*-1)), *af*(*lld_af*,*LOCc*(*ja*+*n*-1)), *b*(*lld_b*,*LOCc*(*jb*+*nrhs*-1)), *work*(*lwork*).

The array *a* contains the matrix *A*. If *fact* = 'F' and *equed* is not 'N', then *A* must have been equilibrated by the scaling factors in *r* and/or *c*.

The array *af* is an input argument if *fact* = 'F'. In this case it contains on entry the factored form of the matrix *A*, that is, the factors *L* and *U* from the factorization *A* = *P***L***U* as computed by p?getrf. If *equed* is not 'N', then *af* is the factored form of the equilibrated matrix *A*.

The array *b* contains on entry the matrix *B* whose columns are the right-hand sides for the systems of equations.

work is a workspace array. The size of *work* is (*lwork*).

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1), respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

iaf, *jaf*

(global) INTEGER. The row and column indices in the global matrix *AF* indicating the first row and the first column of the subarray *af(iaf:iaf+n-1, jaf:jaf+n-1)*, respectively.

descaf

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *AF*.

ib, *jb*

(global) INTEGER. The row and column indices in the global matrix *B* indicating the first row and the first column of the submatrix *B(ib:ib+n-1, jb:jb+nrhs-1)*, respectively.

descb

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

ipiv

(local) INTEGER Array of size *LOCr(m_a)+mb_a*.

The array *ipiv* is an input argument if *fact = 'F'* .

On entry, it contains the pivot indices from the factorization *A = P*L*U* as computed by p?getrf; (local) row i of the matrix was interchanged with the (global) row *ipiv*(i).

This array must be aligned with *A(ia:ia+n-1, *)*.

equed

(global) CHARACTER*1. Must be 'N', 'R', 'C', or 'B'. *equed* is an input argument if *fact* = 'F' . It specifies the form of equilibration that was done:

If *equed* = 'N', no equilibration was done (always true if *fact* = 'N');

If *equed* = 'R', row equilibration was done, that is, *A* has been premultiplied by diag(*r*);

If *equed* = 'C', column equilibration was done, that is, *A* has been postmultiplied by diag(*c*);

If *equed* = 'B', both row and column equilibration was done; *A* has been replaced by diag(*r*)**A**diag(*c*).

r, *c*

(local) REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.

Arrays of size *LOCr*(m_a) and *LOCc*(n_a), respectively.

The array *r* contains the row scale factors for *A*, and the array *c* contains the column scale factors for *A*. These arrays are input arguments if *fact* = 'F' only; otherwise they are output arguments. If *equed* = 'R' or 'B', *A* is multiplied on the left by diag(*r*); if *equed* = 'N' or 'C', *r* is not accessed.

If *fact* = 'F' and *equed* = 'R' or 'B', each element of *r* must be positive.

If *equed* = 'C' or 'B', *A* is multiplied on the right by diag(*c*); if *equed* = 'N' or 'R', *c* is not accessed.

If *fact* = 'F' and *equed* = 'C' or 'B', each element of *c* must be positive. Array *r* is replicated in every process column, and is aligned with the distributed matrix *A*. Array *c* is replicated in every process row, and is aligned with the distributed matrix *A*.

ix, *jx*
(global) INTEGER. The row and column indices in the global matrix *X* indicating the first row and the first column of the submatrix *X*(*ix:ix+n-1*, *jx:jx+nrhs-1*), respectively.

descx
(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *X*.

lwork
(local or global) INTEGER. The size of the array *work* ; must be at least max(p?gecon(*lwork*), p?gerfs(*lwork*))+*LOCr*(n_a).

iwork
(local, psgesvx/pdgesvx only)INTEGER. Workspace array. The size of *iwork* is (*liwork*).

liwork
(local, psgesvx/pdgesvx only)INTEGER. The size of the array *iwork* , must be at least *LOCr*(n_a).

rwork
(local) REAL for pcgesvx

DOUBLE PRECISION for pzgesvx.

Workspace array, used in complex flavors only.

The size of *rwork* is (*lrwork*).

lrwork
(local or global, pcgesvx/pzgesvx only)INTEGER. The size of the array *rwork*;must be at least 2**LOCc*(n_a) .

Output Parameters

x
(local)

REAL for psgesvx

DOUBLE PRECISION for pdgesvx

COMPLEX for pcgesvx

DOUBLE COMPLEX for pzgesvx.

Pointer into the local memory to an array of local size *x*(lld_x,*LOCc*(*jx+nrhs-1*)).

If *info* = 0, the array *x* contains the solution matrix *X* to the *original* system of equations. Note that *A* and *B* are modified on exit if *equed*≠'N', and the solution to the *equilibrated* system is:

diag(*C*)-1**X*, if *trans* = 'N' and *equed* = 'C' or 'B'; and diag(*R*)-1**X*, if *trans* = 'T' or 'C' and *equed* = 'R' or 'B'.

a
Array *a* is not modified on exit if *fact* = 'F' or 'N', or if *fact* = 'E' and *equed* = 'N'.

If *equed*≠'N', *A* is scaled on exit as follows:

equed = 'R': *A* = diag(*R*)**A*

equed = 'C': *A* = *A**diag(*c*)

equed = 'B': *A* = diag(*R*)**A**diag(*c*)

af

If *fact* = 'N' or 'E', then *af* is an output argument and on exit returns the factors *L* and *U* from the factorization *A* = *P*L*U* of the original matrix *A* (if *fact* = 'N') or of the equilibrated matrix *A* (if *fact* = 'E'). See the description of *a* for the form of the equilibrated matrix.

b

Overwritten by diag(*R*)*B if *trans* = 'N' and *equed* = 'R' or 'B';

overwritten by diag(*c*)*B if *trans* = 'T' and *equed* = 'C' or 'B'; not changed if *equed* = 'N'.

r, *c*

These arrays are output arguments if *fact*≠'F'.

See the description of *r*, *c* in *Input Arguments* section.

rcond

(global)REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal condition number of the matrix *A* after equilibration (if done). The routine sets *rcond* =0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime *rcond* is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

ferr, *berr*

(local)REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Arrays of size *LOCc*(n_b) each. Contain the component-wise forward and relative backward errors, respectively, for each solution vector.

Arrays *ferr* and *berr* are both replicated in every process row, and are aligned with the matrices *B* and *X*.

ipiv

If *fact* = 'N' or 'E', then *ipiv* is an output argument and on exit contains the pivot indices from the factorization *A* = *P*L*U* of the original matrix *A* (if *fact* = 'N') or of the equilibrated matrix *A* (if *fact* = 'E').

equed

If *fact*≠'F' , then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

work(1)

If *info*=0, on exit *work*(1) returns the minimum value of *lwork* required for optimum performance.

iwork(1)

If *info*=0, on exit *iwork*(1) returns the minimum value of *liwork* required for optimum performance.

rwork(1)

If *info*=0, on exit *rwork*(1) returns the minimum value of *lrwork* required for optimum performance.

info

INTEGER. If *info*=0, the execution is successful.

info < 0: if the *i*th argument is an array and the *j*th entry had an illegal value, then *info* = −(*i**100+*j*); if the *i*th argument is a scalar and had an illegal value, then *info* = −*i*. If *info* = *i*, and *i* ≤ *n*, then *U*(*i*,*i*) is exactly zero. The factorization has been completed, but the factor *U* is exactly singular, so the solution and error bounds could not be computed. If *info* = *i*, and *i* = *n* +1, then *U* is nonsingular, but *rcond* is less than

machine precision. The factorization has been completed, but the matrix is singular to working precision and the solution and error bounds have not been computed.

p?gbsv

Computes the solution to the system of linear equations with a general banded distributed matrix and multiple right-hand sides.

Syntax

```
call psgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
call pdgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
call pcgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
call pzgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
```

Include Files

Description

The p?gbsvroutine computes the solution to a real or complex system of linear equations

sub(*A*)**X* = sub(*B*),

where sub(*A*) = *A*(*1:n*, *ja:ja+n-1*) is an *n*-by-*n* real/complex general banded distributed matrix with *bwl* subdiagonals and *bwu* superdiagonals, and *X* and sub(*B*)= *B*(*ib:ib+n-1*, *1:rhs*) are *n*-by-*nrhs* distributed matrices.

The *LU* decomposition with partial pivoting and row interchanges is used to factor sub(*A*) as sub(*A*) = *P*L*U*Q*, where *P* and *Q* are permutation matrices, and *L* and *U* are banded lower and upper triangular matrices, respectively. The matrix *Q* represents reordering of columns for the sake of parallelism, while *P* represents reordering of rows for numerical stability using classic partial pivoting.

Input Parameters

n — (global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed matrix sub(*A*) (*n*≥ 0).

bwl — (global) INTEGER. The number of subdiagonals within the band of *A* (0≤ *bwl* ≤ *n-1*).

bwu — (global) INTEGER. The number of superdiagonals within the band of *A* (0≤ *bwu* ≤ *n-1*).

nrhs — (global) INTEGER. The number of right hand sides; the number of columns of the distributed matrix sub(*B*) (*nrhs*≥ 0).

a, *b*

(local)

REAL for psgbsv

DOUBLE PRECISON for pdgbsv

COMPLEX for pcgbsv

DOUBLE COMPLEX for pzgbsv.

Pointers into the local memory to arrays of local size *a*(*lld_a*,*LOCc*(*ja*+*n*-1)) and *b*(*lld_b*,*LOCc*(*nrhs*)).

On entry, the array *a* contains the local pieces of the global array *A*.

On entry, the array *b* contains the right hand side distributed matrix sub(*B*).

ja

(global) INTEGER. The index in the global matrix *A* indicating the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

If *desca*(*dtype_*) = 501, then *dlen_* ≥ 7;

else if *desca*(*dtype_*) = 1, then *dlen_* ≥ 9.

ib

(global) INTEGER. The row index in the global matrix *B* indicating the first row of the matrix to be operated on (which may be either all of *B* or a submatrix of *B*).

descb

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

If *descb*(*dtype_*) = 502, then *dlen_* ≥ 7;

else if *descb*(*dtype_*) = 1, then *dlen_* ≥ 9.

work

(local)

REAL for psgbsv

DOUBLE PRECISON for pdgbsv

COMPLEX for pcgbsv

DOUBLE COMPLEX for pzgbsv.

Workspace array of size *lwork*.

lwork

(local or global) INTEGER. The size of the array *work*, must be at least

lwork ≥ (NB+*bwu*)*(*bwl*+*bwu*)+6*(*bwl*+*bwu*)*(*bwl*+2*bwu*) +

+ max(*nrhs* *(NB+2*bwl*+4*bwu*), 1).

Output Parameters

a

On exit, contains details of the factorization. Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

b	On exit, this array contains the local pieces of the solution distributed matrix *X*.
ipiv	(local) INTEGER array. The size of *ipiv* must be at least *desca*(NB). This array contains pivot indices for local factorizations. You should not alter the contents between factorization and solve.
work(1)	On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.
info	INTEGER. If *info*=0, the execution is successful. *info* < 0: If the *i*th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*th argument is a scalar and had an illegal value, then *info* = -*i*. *info*> 0: If *info* = k ≤ NPROCS, the submatrix stored on processor *info* and factored locally was not nonsingular, and the factorization was not completed. If *info* = k > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?dbsv

Solves a general band system of linear equations.

Syntax

```
call psdbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pddbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pcdbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pzdbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
```

Include Files

Description

The p?dbsvroutine solves the following system of linear equations:

A(1:*n*, *ja*:*ja*+*n*-1)* *X* = *B*(*ib*:*ib*+*n*-1, 1:*nrhs*),

where *A*(1:*n*, *ja*:*ja*+*n*-1) is an *n*-by-*n* real/complex banded diagonally dominant-like distributed matrix with bandwidth *bwl*, *bwu*.

Gaussian elimination without pivoting is used to factor a reordering of the matrix into *LU*.

Input Parameters

n

(global) INTEGER. The order of the distributed submatrix *A*, (*n*≥ 0).

bwl

(global) INTEGER. Number of subdiagonals. 0 ≤ *bwl* ≤ *n*-1.

bwu

(global) INTEGER. Number of subdiagonals. 0 ≤ *bwu* ≤ *n*-1.

nrhs

(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix *B*, (*nrhs* ≥ 0).

a

(local). REAL for psdbsv

DOUBLE PRECISION for pddbsv

COMPLEX for pcdbsv

DOUBLE COMPLEX for pzdbsv.

Pointer into the local memory to an array with leading size *lld_a* ≥ (*bwl* +*bwu*+1) (stored in *desca*). On entry, this array contains the local pieces of the distributed matrix.

ja

(global) INTEGER. The index in the global matrix *A* indicating the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca

(global and local) INTEGER array of size *dlen*.

If 1*d* type (*dtype_a*=501 or 502), *dlen* ≥ 7;

If 2*d* type (*dtype_a*=1), *dlen* ≥ 9.

The array descriptor for the distributed matrix *A*.

Contains information of mapping of *A* to memory.

b

(local)

REAL for psdbsv

DOUBLE PRECISON for pddbsv

COMPLEX for pcdbsv

DOUBLE COMPLEX for pzdbsv.

Pointer into the local memory to an array of local lead size *lld_b* ≥ *nb*. On entry, this array contains the local pieces of the right hand sides *B*(*ib*:*ib* +*n*-1, 1:*nrhs*).

ib

(global) INTEGER. The row index in the global matrix *B* indicating the first row of the matrix to be operated on (which may be either all of *b* or a submatrix of *B*).

descb

(global and local) INTEGER array of size *dlen*.

If 1*d* type (*dtype_b* =502), *dlen* ≥ 7;

If 2*d* type (*dtype_b* =1), *dlen* ≥ 9.

The array descriptor for the distributed matrix *B*.

Contains information of mapping of *B* to memory.

work (local).

`REAL` for `psdbsv`

`DOUBLE PRECISON` for `pddbsv`

`COMPLEX` for `pcdbsv`

`DOUBLE COMPLEX` for `pzdbsv`.

Temporary workspace. This space may be overwritten in between calls to routines. *work* must be the size given in *lwork*.

lwork (local or global) `INTEGER`. Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*`(1)` and an error code is returned.

lwork ≥ *nb*(*bwl*+*bwu*)+6max(*bwl*,*bwu*)*max(*bwl*,*bwu*)
+max((max(*bwl*,*bwu*)*nrhs*), max(*bwl*,*bwu*)*max(*bwl*,*bwu*))

Output Parameters

a On exit, this array contains information containing details of the factorization.

Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

b On exit, this contains the local piece of the solutions distributed matrix *X*.

work On exit, *work*`(1)` contains the minimal *lwork*.

info (local) `INTEGER`. If *info*=0, the execution is successful.

< 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

> 0: If *info* = *k* < NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.

If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

p?dtsv

Solves a general tridiagonal system of linear equations.

Syntax

```
call psdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pddtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pcdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pzdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
```

Include Files

Description

The routine solves a system of linear equations

`A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),`

where `A(1:n, ja:ja+n-1)` is an *n*-by-*n* complex tridiagonal diagonally dominant-like distributed matrix.

Gaussian elimination without pivoting is used to factor a reordering of the matrix into *L U*.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Input Parameters

n	(global) INTEGER. The order of the distributed submatrix *A*(*n*≥ 0).
nrhs	INTEGER. The number of right hand sides; the number of columns of the distributed matrix *B*(*nrhs*≥ 0).
dl	(local).REAL for psdtsv DOUBLE PRECISION for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtsv. Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, *dl*(1) is not referenced, and *dl* must be aligned with *d*. Must be of size > *desca*(*nb_*).
d	(local). REAL for psdtsv DOUBLE PRECISION for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtsv. Pointer to local part of global vector storing the main diagonal of the matrix.
du	(local). REAL for psdtsv DOUBLE PRECISION for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtsv. Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, *du*(*n*) is not referenced, and *du* must be aligned with *d*.
ja	(global) INTEGER. The index in the global matrix *A* indicating the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).
desca	(global and local) INTEGER array of size *dlen*.

If 1*d type* (*dtype_a*=501 or 502), *dlen* ≥ 7;

If 2*d type* (*dtype_a*=1), *dlen* ≥ 9.

The array descriptor for the distributed matrix *A*.

Contains information of mapping of *A* to memory.

b (local)

REAL for psdtsv

DOUBLE PRECISON for pddtsv

COMPLEX for pcdtsv

DOUBLE COMPLEX for pzdtsv.

Pointer into the local memory to an array of local lead size *lld_b* > *nb*. On entry, this array contains the local pieces of the right hand sides *B*(*ib*:*ib* +*n*-1, 1:*nrhs*).

ib (global) INTEGER. The row index in the global matrix *B* indicating the first row of the matrix to be operated on (which may be either all of *b* or a submatrix of *B*).

descb (global and local) INTEGER array of size *dlen*.

If 1*d type* (*dtype_b* =502), *dlen* ≥ 7;

If 2*d type* (*dtype_b* =1), *dlen* ≥ 9.

The array descriptor for the distributed matrix *B*.

Contains information of mapping of *B* to memory.

work (local).

REAL for psdtsv

DOUBLE PRECISON for pddtsv

COMPLEX for pcdtsv

DOUBLE COMPLEX for pzdtsv. Temporary workspace. This space may be overwritten in between calls to routines. *work* must be the size given in *lwork*.

lwork (local or global) INTEGER. Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned. *lwork* > (12*NPCOL+3**nb*)+max((10+2*min(100, *nrhs*))*NPCOL+4**nrhs*, 8*NPCOL)

Output Parameters

dl On exit, this array contains information containing the * factors of the matrix.

d On exit, this array contains information containing the * factors of the matrix. Must be of size > *desca*(*nb_*).

du On exit, this array contains information containing the * factors of the matrix. Must be of size > *desca*(*nb_*).

b	On exit, this contains the local piece of the solutions distributed matrix *X*.
work	On exit, *work*(1) contains the minimal *lwork*.
info	(local) INTEGER. If *info*=0, the execution is successful. < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*. > 0: If *info* = *k*<NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed. If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

p?posv

Solves a symmetric positive definite system of linear equations.

Syntax

call psposv(*uplo*, *n*, *nrhs*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *info*)

call pdposv(*uplo*, *n*, *nrhs*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *info*)

call pcposv(*uplo*, *n*, *nrhs*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *info*)

call pzposv(*uplo*, *n*, *nrhs*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *info*)

Include Files

Description

The p?posvroutine computes the solution to a real/complex system of linear equations

sub(*A*)**X* = sub(*B*),

where sub(*A*) denotes *A*(*ia*:*ia*+*n*-1,*ja*:*ja*+*n*-1) and is an *n*-by-*n* symmetric/Hermitian distributed positive definite matrix and *X* and sub(*B*) denoting *B*(*ib*:*ib*+*n*-1,*jb*:*jb*+*nrhs*-1) are *n*-by-*nrhs* distributed matrices. The Cholesky decomposition is used to factor sub(*A*) as

sub(*A*) = U^T**U*, if *uplo* = 'U', or

sub(*A*) = *L**L^T, if *uplo* = 'L',

where *U* is an upper triangular matrix and *L* is a lower triangular matrix. The factored form of sub(*A*) is then used to solve the system of equations.

Input Parameters

uplo	(global) CHARACTER. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of sub(*A*) is stored.
n	(global) INTEGER. The order of the distributed matrix sub(*A*) (*n*≥ 0).

nrhs INTEGER. The number of right-hand sides; the number of columns of the distributed matrix sub(*B*) (*nrhs*≥ 0).

a (local)

REAL for psposv

DOUBLE PRECISION for pdposv

COMPLEX for pcposv

COMPLEX*16 for pzposv.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)). On entry, this array contains the local pieces of the *n*-by-*n* symmetric distributed matrix sub(*A*) to be factored.

If *uplo* = '*U*', the leading *n*-by-*n* upper triangular part of sub(*A*) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If *uplo* = '*L*', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.

ia, *ja* (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

b (local)

REAL for psposv

DOUBLE PRECISON for pdposv

COMPLEX for pcposv

COMPLEX*16 for pzposv.

Pointer into the local memory to an array of size (*lld_b*, *LOCc*(*jb* +*nrhs*-1)). On entry, the local pieces of the right hand sides distributed matrix sub(*B*).

ib, *jb* (global) INTEGER. The row and column indices in the global matrix *B* indicating the first row and the first column of the submatrix *B*, respectively.

descb (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

Output Parameters

a On exit, if *info* = 0, this array contains the local pieces of the factor *U* or *L* from the Cholesky factorization sub(*A*) = U^H*U, or *L*L^H.

b On exit, if *info* = 0, sub(*B*) is overwritten by the solution distributed matrix *X*.

info (global) INTEGER.

If *info* =0, the execution is successful.

If *info* < 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* > 0: If *info* = *k*, the leading minor of order *k*, A(*ia*:*ia*+*k*-1, *ja*:*ja*+*k*-1) is not positive definite, and the factorization could not be completed, and the solution has not been computed.

p?posvx

Solves a symmetric or Hermitian positive definite system of linear equations.

Syntax

call psposvx(*fact*, *uplo*, *n*, *nrhs*, *a*, *ia*, *ja*, *desca*, *af*, *iaf*, *jaf*, *descaf*, *equed*, *sr*, *sc*, *b*, *ib*, *jb*, *descb*, *x*, *ix*, *jx*, *descx*, *rcond*, *ferr*, *berr*, *work*, *lwork*, *iwork*, *liwork*, *info*)

call pdposvx(*fact*, *uplo*, *n*, *nrhs*, *a*, *ia*, *ja*, *desca*, *af*, *iaf*, *jaf*, *descaf*, *equed*, *sr*, *sc*, *b*, *ib*, *jb*, *descb*, *x*, *ix*, *jx*, *descx*, *rcond*, *ferr*, *berr*, *work*, *lwork*, *iwork*, *liwork*, *info*)

call pcposvx(*fact*, *uplo*, *n*, *nrhs*, *a*, *ia*, *ja*, *desca*, *af*, *iaf*, *jaf*, *descaf*, *equed*, *sr*, *sc*, *b*, *ib*, *jb*, *descb*, *x*, *ix*, *jx*, *descx*, *rcond*, *ferr*, *berr*, *work*, *lwork*, *iwork*, *liwork*, *info*)

call pzposvx(*fact*, *uplo*, *n*, *nrhs*, *a*, *ia*, *ja*, *desca*, *af*, *iaf*, *jaf*, *descaf*, *equed*, *sr*, *sc*, *b*, *ib*, *jb*, *descb*, *x*, *ix*, *jx*, *descx*, *rcond*, *ferr*, *berr*, *work*, *lwork*, *iwork*, *liwork*, *info*)

Include Files

Description

The p?posvxroutine uses the Cholesky factorization $A=U^T*U$ or $A=L*L^T$ to compute the solution to a real or complex system of linear equations

A(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1)**X* = *B*(*ib*:*ib*+*n*-1, *jb*:*jb*+*nrhs*-1),

where A(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) is a *n*-by-*n* matrix and *X* and *B*(*ib*:*ib*+*n*-1,*jb*:*jb*+*nrhs*-1) are *n*-by-*nrhs* matrices.

Error bounds on the solution and a condition estimate are also provided.

In the following comments *y* denotes *Y*(*iy*:*iy*+*m*-1, *jy*:*jy*+*k*-1), an *m*-by-*k* matrix where *y* can be *a*, *af*, *b* and *x*.

The routine p?posvx performs the following steps:

1. If *fact* = 'E', real scaling factors *s* are computed to equilibrate the system:

   diag(*sr*)**A**diag(*sc*)*inv(diag(*sc*))**X* = diag(*sr*)**B*

   Whether or not the system will be equilibrated depends on the scaling of the matrix *A*, but if equilibration is used, *A* is overwritten by diag(*sr*)**A**diag(*sc*) and *B* by diag(*sr*)**B* .
2. If *fact* = 'N' or 'E', the Cholesky decomposition is used to factor the matrix *A* (after equilibration if *fact* = 'E') as

   $A = U^T*U$, if *uplo* = 'U', or

   $A = L*L^T$, if *uplo* = 'L',

   where *U* is an upper triangular matrix and *L* is a lower triangular matrix.

3. The factored form of *A* is used to estimate the condition number of the matrix *A*. If the reciprocal of the condition number is less than machine precision, steps 4-6 are skipped
4. The system of equations is solved for *X* using the factored form of *A*.
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix *X* is premultiplied by diag(*sr*) so that it solves the original system before equilibration.

Input Parameters

fact

(global) CHARACTER. Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix *A* is supplied on entry, and if not, whether the matrix *A* should be equilibrated before it is factored.

If *fact* = 'F': on entry, *af* contains the factored form of *A*. If *equed* = 'Y', the matrix *A* has been equilibrated with scaling factors given by *s*. *a* and *af* will not be modified.

If *fact* = 'N', the matrix *A* will be copied to *af* and factored.

If *fact* = 'E', the matrix *A* will be equilibrated if necessary, then copied to *af* and factored.

uplo

(global) CHARACTER. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of *A* is stored.

n

(global) INTEGER. The order of the distributed matrix sub(*A*) (*n*≥ 0).

nrhs

(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrices *B* and *X*. (*nrhs*≥ 0).

a

(local)

REAL for psposvx

DOUBLE PRECISION for pdposvx

COMPLEX for pcposvx

DOUBLE COMPLEX for pzposvx.

Pointer into the local memory to an array of local size (*lld_a*, *LOCc*(*ja*+*n*-1)). On entry, the symmetric/Hermitian matrix *A*, except if *fact* = 'F' and *equed* = 'Y', then *A* must contain the equilibrated matrix diag(*sr*)*A*diag(*sc*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *A* contains the upper triangular part of the matrix *A*, and the strictly lower triangular part of *A* is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *A* contains the lower triangular part of the matrix *A*, and the strictly upper triangular part of *A* is not referenced. *A* is not modified if *fact* = 'F' or 'N', or if *fact* = 'E' and *equed* = 'N' on exit.

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

af (local)

REAL for psposvx

DOUBLE PRECISION for pdposvx

COMPLEX for pcposvx

DOUBLE COMPLEX for pzposvx.

Pointer into the local memory to an array of local size (*lld_af*, *LOCc*(*ja*+*n*-1)).

If *fact* = 'F', then *af* is an input argument and on entry contains the triangular factor *U* or *L* from the Cholesky factorization $A = U^T*U$ or $A = L*L^T$, in the same storage format as *A*. If *equed* ≠ 'N', then *af* is the factored form of the equilibrated matrix diag(*sr*)*A*diag(*sc*).

iaf, *jaf* (global) INTEGER. The row and column indices in the global matrix *AF* indicating the first row and the first column of the submatrix *AF*, respectively.

descaf (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *AF*.

equed (global) CHARACTER. Must be 'N' or 'Y'.

equed is an input argument if *fact* = 'F'. It specifies the form of equilibration that was done:

If *equed* = 'N', no equilibration was done (always true if *fact* = 'N');

If *equed* = 'Y', equilibration was done and *A* has been replaced by diag(*sr*)*A*diag(*sc*).

sr (local)

REAL for psposvx

DOUBLE PRECISION for pdposvx

COMPLEX for pcposvx

DOUBLE COMPLEX for pzposvx.

Array of size *lld_a*.

The array *s* contains the scale factors for *A*. This array is an input argument if *fact* = 'F' only; otherwise it is an output argument.

If *equed* = 'N', *s* is not accessed.

If *fact* = 'F' and *equed* = 'Y', each element of *s* must be positive.

b (local)

REAL for psposvx

DOUBLE PRECISION for pdposvx

COMPLEX for pcposvx

DOUBLE COMPLEX for pzposvx.

Pointer into the local memory to an array of local size (*lld_b*, *LOCc*(*jb*+*nrhs*-1)). On entry, the *n*-by-*nrhs* right-hand side matrix *B*.

ib, *jb*

(global) INTEGER. The row and column indices in the global matrix *B* indicating the first row and the first column of the submatrix *B*, respectively.

descb

(global and local) INTEGER. Array of size *dlen_*. The array descriptor for the distributed matrix *B*.

x

(local)

REAL for psposvx

DOUBLE PRECISION for pdposvx

COMPLEX for pcposvx

DOUBLE COMPLEX for pzposvx.

Pointer into the local memory to an array of local size (*lld_x*, *LOCc*(*jx*+*nrhs*-1)).

ix, *jx*

(global) INTEGER. The row and column indices in the global matrix *X* indicating the first row and the first column of the submatrix *X*, respectively.

descx

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *X*.

work

(local)

REAL for psposvx

DOUBLE PRECISION for pdposvx

COMPLEX for pcposvx

DOUBLE COMPLEX for pzposvx.

Workspace array of size *lwork*.

lwork

(local or global) INTEGER.

The size of the array *work*. *lwork* is local input and must be at least *lwork* = max(p?pocon(*lwork*), p?porfs(*lwork*)) + *LOCr*(*n_a*).

lwork = 3**desca*(*lld_*).

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

iwork

(local) INTEGER. Workspace array of size *liwork*.

liwork

(local or global)

INTEGER. The size of the array *iwork*. *liwork* is local input and must be at least *liwork* = *desca*(*lld_*)*liwork* = *LOCr*(*n_a*).

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a

On exit, if *fact* = 'E' and *equed* = 'Y', *a* is overwritten by diag(*sr*)*a*diag(*sc*).

af

If *fact* = 'N', then *af* is an output argument and on exit returns the triangular factor *U* or *L* from the Cholesky factorization $A = U^T*U$ or $A = L*L^T$ of the original matrix *A*.

If *fact* = 'E', then *af* is an output argument and on exit returns the triangular factor *U* or *L* from the Cholesky factorization $A = U^T*U$ or $A = L*L^T$ of the equilibrated matrix *A* (see the description of *A* for the form of the equilibrated matrix).

equed

If *fact*≠'F' , then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

sr

This array is an output argument if *fact*≠'F'.

See the description of *sr* in *Input Arguments* section.

sc

This array is an output argument if *fact*≠'F'.

See the description of *sc* in *Input Arguments* section.

b

On exit, if *equed* = 'N', *b* is not modified; if *trans* = 'N' and *equed* = 'R' or 'B', *b* is overwritten by diag(*r*)*b; if *trans* = 'T' or 'C' and *equed* = 'C' or 'B', *b* is overwritten by diag(*c*)*b.

x

(local)

REAL for psposvx

DOUBLE PRECISION for pdposvx

COMPLEX for pcposvx

DOUBLE COMPLEX for pzposvx.

If *info* = 0 the *n*-by-*nrhs* solution matrix *X* to the original system of equations.

Note that *A* and *B* are modified on exit if *equed*≠'N', and the solution to the equilibrated system is

inv(diag(*sc*))*X if *trans* = 'N' and *equed* = 'C' or 'B', or

inv(diag(*sr*))*X if *trans* = 'T' or 'C' and *equed* = 'R' or 'B'.

rcond

(global)

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision (in particular, if *rcond*=0), the matrix is singular to working precision. This condition is indicated by a return code of *info* > 0.

ferr

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

Arrays of size at least max(*LOC*, *n_b*). The estimated forward error bounds for each solution vector *X*(*j*) (the *j*-th column of the solution matrix *X*). If *xtrue* is the true solution, *ferr*(*j*) bounds the magnitude of the largest entry in (*X*(*j*) – *xtrue*) divided by the magnitude of the largest entry in *X*(*j*). The quality of the error bound depends on the quality of the estimate of norm(inv(*A*)) computed in the code; if the estimate of norm(inv(*A*)) is accurate, the error bound is guaranteed.

berr (local)

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

Arrays of size at least max(*LOC*, *n_b*). The componentwise relative backward error of each solution vector *X*(*j*) (the smallest relative change in any entry of *A* or *B* that makes *X*(*j*) an exact solution).

work(1) (local) On exit, *work*(1) returns the minimal and optimal *liwork*.

info (global) INTEGER.

If *info*=0, the execution is successful.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value

> 0: if *info* = *i*, and *i* is ≤ *n*: if *info* = *i*, the leading minor of order *i* of *a* is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed.

= *n*+1: *rcond* is less than machine precision. The factorization has been completed, but the matrix is singular to working precision, and the solution and error bounds have not been computed.

call pzpbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
```

Include Files

Description

The p?pbsvroutine solves a system of linear equations

A(1:*n*, *ja*:*ja*+*n*-1)***X* = *B*(*ib*:*ib*+*n*-1, 1:*nrhs*),

where A(1:n, ja:ja+n-1) is an *n*-by-*n* real/complex banded symmetric positive definite distributed matrix with bandwidth *bw*.

Cholesky factorization is used to factor a reordering of the matrix into *L***L'*.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Input Parameters

uplo

(global) CHARACTER. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular of *A* is stored.

If *uplo* = 'U', the upper triangular *A* is stored

If *uplo* = 'L', the lower triangular of *A* is stored.

n

(global) INTEGER. The order of the distributed matrix *A* (*n*≥ 0).

bw

(global) INTEGER. The number of subdiagonals in *L* or *U*. 0 ≤ *bw* ≤ *n*-1.

nrhs

(global) INTEGER. The number of right-hand sides; the number of columns in *B* (*nrhs*≥ 0).

a

(local). REAL for pspbsv

DOUBLE PRECISON for pdpbsv

COMPLEX for pcpbsv

DOUBLE COMPLEX for pzpbsv.

Pointer into the local memory to an array with leading size *lld_a* ≥ (*bw* +1) (stored in *desca*). On entry, this array contains the local pieces of the distributed matrix sub(*A*) to be factored.

ja

(global) INTEGER. The index in the global matrix *A* indicating the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

b

(local)

REAL for pspbsv

DOUBLE PRECISON for pdpbsv

COMPLEX for pcpbsv

DOUBLE COMPLEX for pzpbsv.

Pointer into the local memory to an array of local lead size *lld_b* ≥ *nb*. On entry, this array contains the local pieces of the right hand sides *B*(*ib*:*ib* +*n*-1, 1:*nrhs*).

ib (global) INTEGER. The row index in the global matrix *B* indicating the first row of the matrix to be operated on (which may be either all of *b* or a submatrix of *B*).

descb (global and local) INTEGER array of size *dlen*.

If 1D type (*dtype_b* =502), *dlen* ≥ 7;

If 2D type (*dtype_b* =1), *dlen* ≥ 9.

The array descriptor for the distributed matrix *B*.

Contains information of mapping of *B* to memory.

work (local).

REAL for pspbsv

DOUBLE PRECISON for pdpbsv

COMPLEX for pcpbsv

DOUBLE COMPLEX for pzpbsv.

Temporary workspace. This space may be overwritten in between calls to routines. *work* must be the size given in *lwork*.

lwork (local or global) INTEGER. Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned. *lwork* ≥ (*nb*+2*bw*)*bw* +max((*bw*nrhs*), *bw*bw*)

Output Parameters

a On exit, this array contains information containing details of the factorization. Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

b On exit, contains the local piece of the solutions distributed matrix *X*.

work On exit, *work*(1) contains the minimal *lwork*.

info (global) INTEGER. If *info*=0, the execution is successful.

< 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i*100+j)*, if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

> 0: If *info* = *k* ≤ NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.

If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

If 1*d* type (*dtype_b* = 502), *dlen* ≥ 7;

If 2*d* type (*dtype_b* = 1), *dlen* ≥ 9.

The array descriptor for the distributed matrix *B*.

Contains information of mapping of *B* to memory.

work (local).

REAL for psptsv

DOUBLE PRECISON for pdptsv

COMPLEX for pcptsv

DOUBLE COMPLEX for pzptsv.

Temporary workspace. This space may be overwritten in between calls to routines. *work* must be the size given in *lwork*.

lwork (local or global) INTEGER. Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned. *lwork* > (12*NPCOL+3**nb*)+max((10+2*min(100, *nrhs*))*NPCOL+4**nrhs*, 8*NPCOL).

Output Parameters

d On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to *desca*(*nb_*).

e On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to *desca*(*nb_*).

b On exit, this contains the local piece of the solutions distributed matrix *X*.

work	On exit, *work*(1) contains the minimal *lwork*.
info	(local) INTEGER. If *info*=0, the execution is successful. < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*. > 0: If *info* = *k* ≤ NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed. If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

p?gels

Solves overdetermined or underdetermined linear systems involving a matrix of full rank.

Syntax

```
call psgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
call pdgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
call pcgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
call pzgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
```

Include Files

Description

The p?gels routine solves overdetermined or underdetermined real/ complex linear systems involving an *m*-by-*n* matrix sub(*A*) = *A*(*ia*:*ia*+*m*-1,*ja*:*ja*+*n*-1), or its transpose/ conjugate-transpose, using a *QTQ* or *LQ* factorization of sub(*A*). It is assumed that sub(*A*) has full rank.

The following options are provided:

1. If *trans* = 'N' and *m*≥*n*: find the least squares solution of an overdetermined system, that is, solve the least squares problem

   minimize ||sub(*B*) - sub(*A*)**X*||
2. If *trans* = 'N' and *m* < *n*: find the minimum norm solution of an underdetermined system sub(*A*)**X* = sub(*B*).
3. If *trans* = 'T' and *m*≥*n*: find the minimum norm solution of an undetermined system sub(*A*)^T**X* = sub(*B*).
4. If *trans* = 'T' and *m* < *n*: find the least squares solution of an overdetermined system, that is, solve the least squares problem

   minimize ||sub(*B*) - sub(*A*)^T**X*||,

   where sub(*B*) denotes *B*(*ib*:*ib*+*m*-1, *jb*:*jb*+*nrhs*-1) when *trans* = 'N' and *B*(*ib*:*ib*+*n*-1, *jb*:*jb*+*nrhs*-1) otherwise. Several right hand side vectors *b* and solution vectors *x* can be handled in a single call; when *trans* = 'N', the solution vectors are stored as the columns of the *n*-by-*nrhs* right hand side matrix sub(*B*) and the *m*-by-*nrhs* right hand side matrix sub(*B*) otherwise.

Input Parameters

trans

(global) CHARACTER. Must be 'N', or 'T'.

If *trans* = 'N', the linear system involves matrix sub(*A*);

If *trans* = 'T', the linear system involves the transposed matrix A^T (for real flavors only).

m

(global) INTEGER. The number of rows in the distributed matrix sub (*A*) (*m*≥ 0).

n

(global) INTEGER. The number of columns in the distributed matrix sub (*A*) (*n*≥ 0).

nrhs

(global) INTEGER. The number of right-hand sides; the number of columns in the distributed submatrices sub(*B*) and *X*. (*nrhs*≥ 0).

a

(local)

REAL for psgels

DOUBLE PRECISION for pdgels

COMPLEX for pcgels

DOUBLE COMPLEX for pzgels.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)). On entry, contains the *m*-by-*n* matrix *A*.

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

b

(local)

REAL for psgels

DOUBLE PRECISION for pdgels

COMPLEX for pcgels

DOUBLE COMPLEX for pzgels.

Pointer into the local memory to an array of local size (*lld_b*, *LOCc*(*jb* +*nrhs*-1)). On entry, this array contains the local pieces of the distributed matrix *B* of right-hand side vectors, stored columnwise; sub(*B*) is *m*-by-*nrhs* if *trans*='N', and *n*-by-*nrhs* otherwise.

ib, *jb*

(global) INTEGER. The row and column indices in the global matrix *B* indicating the first row and the first column of the submatrix *B*, respectively.

descb

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

work

(local)

REAL for psgels

DOUBLE PRECISION for pdgels

COMPLEX for pcgels

DOUBLE COMPLEX for pzgels.

Workspace array with size *lwork*.

lwork (local or global) INTEGER.

The size of the array *work*|*lwork* is local input and must be at least $lwork \geq ltau + \max(lwf, lws)$, where if $m > n$, then

$ltau = \text{numroc}(ja+\min(m,n)-1, nb\_a, \text{MYCOL}, csrc\_a, \text{NPCOL})$,

$lwf = nb\_a*(mpa0 + nqa0 + nb\_a)$

$lws = \max((nb\_a*(nb\_a-1))/2, (nrhsqb0 + mpb0)*nb\_a) + nb\_a*nb\_a$

else

$ltau = \text{numroc}(ia+\min(m,n)-1, mb\_a, \text{MYROW}, rsrc\_a, \text{NPROW})$,

$lwf = mb\_a * (mpa0 + nqa0 + mb\_a)$

$lws = \max((mb\_a*(mb\_a-1))/2, (npb0 + \max(nqa0 + \text{numroc}(\text{numroc}(n+iroffb, mb\_a, 0, 0, \text{NPROW}), mb\_a, 0, 0, lcmp), nrhsqb0))*mb\_a) + mb\_a*mb\_a$

end if,

where $lcmp = lcm/\text{NPROW}$ with $lcm = \text{ilcm}(\text{NPROW}, \text{NPCOL})$,

$iroffa = \text{mod}(ia-1, mb\_a)$,

$icoffa = \text{mod}(ja-1, nb\_a)$,

$iarow = \text{indxg2p}(ia, mb\_a, \text{MYROW}, rsrc\_a, \text{NPROW})$,

$iacol = \text{indxg2p}(ja, nb\_a, \text{MYROW}, rsrc\_a, \text{NPROW})$

$mpa0 = \text{numroc}(m+iroffa, mb\_a, \text{MYROW}, iarow, \text{NPROW})$,

$nqa0 = \text{numroc}(n+icoffa, nb\_a, \text{MYCOL}, iacol, \text{NPCOL})$,

$iroffb = \text{mod}(ib-1, mb\_b)$,

$icoffb = \text{mod}(jb-1, nb\_b)$,

$ibrow = \text{indxg2p}(ib, mb\_b, \text{MYROW}, rsrc\_b, \text{NPROW})$,

$ibcol = \text{indxg2p}(jb, nb\_b, \text{MYCOL}, csrc\_b, \text{NPCOL})$,

$mpb0 = \text{numroc}(m+iroffb, mb\_b, \text{MYROW}, icrow, \text{NPROW})$,

$nqb0 = \text{numroc}(n+icoffb, nb\_b, \text{MYCOL}, ibcol, \text{NPCOL})$,

NOTE
$\text{mod}(x,y)$ is the integer remainder of x/y.

ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW, and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a

On exit, If $m \geq n$, sub(*A*) is overwritten by the details of its *QR* factorization as returned by p?geqrf; if $m < n$, sub(*A*) is overwritten by details of its *LQ* factorization as returned by p?gelqf.

b

On exit, sub(*B*) is overwritten by the solution vectors, stored columnwise: if *trans* = 'N' and $m \geq n$, rows 1 to *n* of sub(*B*) contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $n+1$ to *m* in that column;

If *trans* = 'N' and $m < n$, rows 1 to *n* of sub(*B*) contain the minimum norm solution vectors;

If *trans* = 'T' and $m \geq n$, rows 1 to *m* of sub(*B*) contain the minimum norm solution vectors; if *trans* = 'T' and $m < n$, rows 1 to *m* of sub(*B*) contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $m+1$ to *n* in that column.

work(1)

On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i** 100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?syev

Computes selected eigenvalues and eigenvectors of a symmetric matrix.

Syntax

```
call pssyev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, info)
call pdsyev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, info)
```

Include Files

Description

The p?syevroutine computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A* by calling the recommended sequence of ScaLAPACK routines.

In its present form, the routine assumes a homogeneous system and makes no checks for consistency of the eigenvalues or eigenvectors across the different processes. Because of this, it is possible that a heterogeneous system may return incorrect results without any error messages.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz — (global) CHARACTER. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors:

If *jobz* ='N', then only eigenvalues are computed.

If *jobz* ='V', then eigenvalues and eigenvectors are computed.

uplo — (global) CHARACTER. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric matrix *A* is stored:

If *uplo* = 'U', *a* stores the upper triangular part of *A*.

If *uplo* = 'L', *a* stores the lower triangular part of *A*.

n — (global) INTEGER. The number of rows and columns of the matrix *A* (*n*≥ 0).

a — (local)

REAL for pssyev.

DOUBLE PRECISION for pdsyev.

Block cyclic array of global size (*n*, *n*) and local size (*lld_a*, *LOCc*(*ja* +*n*-1)). On entry, the symmetric matrix *A*.

If *uplo* = 'U', only the upper triangular part of *A* is used to define the elements of the symmetric matrix.

If *uplo* = 'L', only the lower triangular part of *A* is used to define the elements of the symmetric matrix.

ia, *ja* — (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca — (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

iz, *jz* — (global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz — (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*.

work — (local)

REAL for pssyev.

DOUBLE PRECISION for pdsyev.

Array of size *lwork*.

lwork — (local) INTEGER. See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then *lwork* ≥ 5*n* + *sizesytrd* + 1,

where *sizesytrd*is the workspace for p?sytrd and is max(NB*(*np* +1), 3*NB).

If eigenvectors are requested (*jobz* = 'V') then the amount of workspace required to guarantee that all eigenvectors are computed is:

qrmem = 2*n-2

lwmin = 5*n + n*ldc + max(*sizemqrleft*, *qrmem*) + 1

Variable definitions:

nb = *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*);

nn = max(*n*, *nb*, 2);

desca(*rsrc_*) = *desca*(*rsrc_*) = *descz*(*rsrc_*) = *descz*(*csrc_*) = 0

np = numroc(*nn*, *nb*, 0, 0, NPROW)

nq = numroc(max(*n*, *nb*, 2), *nb*, 0, 0, NPCOL)

nrc = numroc(*n*, *nb*, *myprowc*, 0, NPROCS)

ldc = max(1, *nrc*)

sizemqrleft is the workspace for p?ormtr when its *side* argument is 'L'.

myprowc is defined when a new context is created as follows:

call blacs_get(*desca*(*ctxt_*), 0, *contextc*)

call blacs_gridinit(*contextc*, 'R', NPROCS, 1)

call blacs_gridinfo(*contextc*, *nprowc*, *npcolc*, *myprowc*, *mypcolc*)

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a

On exit, the lower triangle (if *uplo*='L') or the upper triangle (if *uplo*='U') of *A*, including the diagonal, is destroyed.

w

(global). REAL for pssyev

DOUBLE PRECISION for pdsyev

Array of size *n*.

On normal exit, the first *m* entries contain the selected eigenvalues in ascending order.

z

(local). REAL for pssyev

DOUBLE PRECISION for pdsyev

Array, global size (*n*, *n*), local size (*lld_z*, *LOCc*(*jz*+*n*-1)). If *jobz* = 'V', then on normal exit the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues.

If *jobz* = 'N', then *z* is not referenced.

work(1)

On output, *work*(1) returns the workspace needed to guarantee completion. If the input parameters are incorrect, *work*(1) may also be incorrect.

If *jobz* = 'N'*work*(1) = minimal (optimal) amount of workspace

If *jobz* = 'V'*work*(1) = minimal workspace required to generate all the eigenvectors.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* > 0:

If *info*= 1 through *n*, the *i*-th eigenvalue did not converge in ?steqr2 after a total of 30*n* iterations.

If *info*= *n*+1, then p?syev has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from p?syev cannot be guaranteed.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?syevd

Computes all eigenvalues and eigenvectors of a real symmetric matrix by using a divide and conquer algorithm.

Syntax

call pssyevd(*jobz*, *uplo*, *n*, *a*, *ia*, *ja*, *desca*, *w*, *z*, *iz*, *jz*, *descz*, *work*, *lwork*, *iwork*, *liwork*, *info*)

call pdsyevd(*jobz*, *uplo*, *n*, *a*, *ia*, *ja*, *desca*, *w*, *z*, *iz*, *jz*, *descz*, *work*, *lwork*, *iwork*, *liwork*, *info*)

Include Files

Description

The p?syevd routine computes all eigenvalues and eigenvectors of a real symmetric matrix *A* by using a divide and conquer algorithm.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz

(global) CHARACTER*1. Must be 'N' or 'V'.

Specifies if it is necessary to compute the eigenvectors:

If *jobz* = 'N', then only eigenvalues are computed.

If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

uplo (global) CHARACTER*1. Must be 'U' or 'L'.

Specifies whether the upper or lower triangular part of the Hermitian matrix *A* is stored:

If *uplo* = 'U', *a* stores the upper triangular part of *A*.

If *uplo* = 'L', *a* stores the lower triangular part of *A*.

n (global) INTEGER. The number of rows and columns of the matrix *A* (*n*≥ 0).

a (local).

REAL for pssyevd

DOUBLE PRECISION for pdsyevd.

Block cyclic array of global size (*n*, *n*) and local size (*lld_a*, *LOCc*(*ja* +*n*-1)). On entry, the symmetric matrix *A*.

If *uplo* = 'U', only the upper triangular part of *A* is used to define the elements of the symmetric matrix.

If *uplo* = 'L', only the lower triangular part of *A* is used to define the elements of the symmetric matrix.

ia, *ja* (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*. If *desca*(*ctxt_*) is incorrect, p?syevd cannot guarantee correct error reporting.

iz, *jz* (global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*. *descz*(*ctxt_*) must equal *desca*(*ctxt_*).

work (local).

REAL for pssyevd

DOUBLE PRECISION for pdsyevd.

Array of size *lwork*.

lwork (local) INTEGER. The size of the array *work*.

If eigenvalues are requested:

lwork≥ max(1+6**n* + 2**np***nq*, *trilwmin*) + 2**n*

with *trilwmin* = 3**n* + max(*nb***(*np* + 1), 3**nb*)

np = numroc(*n*, *nb*, *myrow*, *iarow*, NPROW)

nq = numroc(*n*, *nb*, *mycol*, *iacol*, NPCOL)

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by pxerbla.

iwork (local) INTEGER. Workspace array of size *liwork*.

liwork (local) INTEGER , size of *iwork*.

liwork = 7*n + 8*npcol + 2.

Output Parameters

a On exit, the lower triangle (if *uplo* = 'L'), or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

w (global).

REAL for pssyevd

DOUBLE PRECISION for pdsyevd.

Array of size *n*. If *info* = 0, *w* contains the eigenvalues in the ascending order.

z (local).

REAL for pssyevd

DOUBLE PRECISION for pdsyevd.

Array, global size (*n*, *n*), local size (*lld_z*, *LOCc*(*jz*+*n*-1)).

The *z* parameter contains the orthonormal eigenvectors of the matrix *A*.

work(1) On exit, returns adequate workspace to allow optimal performance.

iwork(1) (local).

On exit, if *liwork* > 0, *iwork*(1) returns the optimal *liwork*.

info (global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*). If the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info*> 0:

The algorithm failed to compute the *info*/(*n*+1)-th eigenvalue while working on the submatrix lying in global rows and columns mod(*info*,*n* +1).

NOTE

mod(*x*,*y*) is the integer remainder of *x*/*y*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?syevr

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix using Relatively Robust Representation.

Syntax

```
call pssyevr( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, m, nz, w, z, iz, jz, descz, work, lwork, iwork, liwork, info )
```

```
call pdsyevr( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, m, nz, w, z, iz, jz, descz, work, lwork, iwork, liwork, info )
```

Include Files

Description

`p?syevr` computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A* distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK routines.

First, the matrix *A* is reduced to real symmetric tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in `w`. The eigenvector matrix `z` is stored in 2D block-cyclic format distributed over all processors.

Note that subsets of eigenvalues/vectors can be selected by specifying a range of values or a range of indices for the desired eigenvalues.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.
Notice revision #20201201

Input Parameters

jobz (global) CHARACTER*1

Specifies whether or not to compute the eigenvectors:

= 'N': Compute eigenvalues only.

= 'V': Compute eigenvalues and eigenvectors.

range (global) CHARACTER*1

= 'A': all eigenvalues will be found.

= 'V': all eigenvalues in the interval [`vl`,`vu`] will be found.

= 'I': the `il`-th through `iu`-th eigenvalues will be found.

uplo (global) CHARACTER*1

Specifies whether the upper or lower triangular part of the symmetric matrix *A* is stored:

= 'U': Upper triangular

= 'L': Lower triangular

n (global) INTEGER

The number of rows and columns of the matrix *a*. *n*≥ 0

a REAL for pssyevr

DOUBLE PRECISION for pdsyevr

Block cyclic array of global size (*n*, *n*), local size (*lld_a*, LOC_c(*ja*+*n*-1)).

This array contains the local pieces of the symmetric distributed matrix *A*. If *uplo* = 'U', only the upper triangular part of *a* is used to define the elements of the symmetric matrix. If *uplo* = 'L', only the lower triangular part of *a* is used to define the elements of the symmetric matrix.

On exit, the lower triangle (if *uplo*='L') or the upper triangle (if *uplo*='U') of *a*, including the diagonal, is destroyed.

ia (global) INTEGER

Global row index in the global matrix *A* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

ja (global) INTEGER

Global column index in the global matrix *A* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

desca (global and local) INTEGER array of size *dlen_*=9.

The array descriptor for the distributed matrix *a*.

vl REAL for pssyevr

DOUBLE PRECISION for pdsyevr

(global)

If *range*='V', the lower bound of the interval to be searched for eigenvalues. Not referenced if *range* = 'A' or 'I'.

vu REAL for pssyevr

DOUBLE PRECISION for pdsyevr

(global)

If *range*='V', the upper bound of the interval to be searched for eigenvalues. Not referenced if *range* = 'A' or 'I'.

il (global) INTEGER

If *range*='I', the index (from smallest to largest) of the smallest eigenvalue to be returned. *il*≥ 1.

Not referenced if *range* = 'A'.

iu (global) INTEGER

If *range*='I', the index (from smallest to largest) of the largest eigenvalue to be returned. min(*il*,*n*) ≤*iu*≤*n*.

Not referenced if *range* = 'A'.

iz

(global) INTEGER

Global row index in the global matrix *Z* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

jz

(global) INTEGER

Global column index in the global matrix *Z* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

descz

INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *z*.

The context *descz*(*ctxt_*) must equal *desca*(*ctxt_*). Also note the array alignment requirements specified below.

work

REAL for pssyevr

DOUBLE PRECISION for pdsyevr

(local workspace) array of size *lwork*

lwork

(local) INTEGER

Size of *work*, must be at least 3.

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N') then

lwork≥ 2 + 5*n + max(12 * *nn*, *neig* * (*np0* + 1))

If eigenvectors are requested (*jobz* = 'V') then the amount of workspace required is:

lwork≥ 2 + 5*n + max(18**nn*, *np0* * *mq0* + 2 * *neig* * *neig*) + (2 + iceil(*neig*, *nprow***npcol*))**nn*

Variable definitions:

neig = number of eigenvectors requested

nb = *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*)

nn = max(*n*, *neig*, 2)

desca(*rsrc_*) = *desca*(*csrc_nb_*) = *descz*(*rsrc_*) = *descz*(*csrc_*) = 0

np0 = numroc(*nn*, *neig*, 0, 0, *nprow*)

mq0 = numroc(max(*neig*, *neig*, 2), *neig*, 0, 0, *npcol*)

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*), and *nprow* and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.

liwork (local) INTEGER

size of *iwork*

Let *nnp* = max(*n*, *nprow***npcol* + 1, 4). Then:

liwork≥ 12**nnp* + 2**n* when the eigenvectors are desired

liwork≥ 10**nnp* + 2**n* when only the eigenvalues have to be computed

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

OUTPUT Parameters

m (global) INTEGER

Total number of eigenvalues found. 0 ≤*m*≤*n*.

nz (global) INTEGER

Total number of eigenvectors computed. 0 ≤*nz*≤*m*.

The number of columns of *z* that are filled.

If *jobz*≠ 'V', *nz* is not referenced.

If *jobz* = 'V', *nz* = *m*

w REAL for pssyevr

DOUBLE PRECISION for pdsyevr

(global) array of size *n*

Upon successful exit, the first *m* entries contain the selected eigenvalues in ascending order.

z REAL for pssyevr

DOUBLE PRECISION for pdsyevr

Block-cyclic array, global size(*n*, *n*), local size (*lld_z*, $LOC_c(jz+n-1)$) .

On exit, contains local pieces of distributed matrix *Z*.

work On return, *work*(1) contains the optimal amount of workspace required for efficient execution. If *jobz*='N' *work*(1) = optimal amount of workspace required to compute the eigenvalues. If *jobz*='V' *work*(1) = optimal amount of workspace required to compute eigenvalues and eigenvectors.

iwork (local workspace) INTEGER array

On return, *iwork*(1) contains the amount of integer workspace required.

info (global) INTEGER

= 0: successful exit

< 0: If the *i*-th argument is an array and the *j*th-entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The distributed submatrices *a*(*ia*:*, *ja*:*) and *z*(*iz*:*iz*+*m*-1,*jz*:*jz*+*n*-1) must satisfy the following alignment properties:

1. Identical (quadratic) dimension: *desca*(*m_*) = *descz*(*m_*) = *desca*(*n_*) = *descz*(*n_*)
2. Quadratic conformal blocking: *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*), *desca*(*rsrc_*) = *descz*(*rsrc_*)
3. mod(*ia*-1, *mb_a*) = mod(*iz*-1, *mb_z*) = 0

NOTE
mod(*x*,*y*) is the integer remainder of *x*/*y*.

```

Include Files

Description

The p?syevxroutine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A* by calling the recommended sequence of ScaLAPACK routines. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz (global) CHARACTER*1. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors:

If *jobz* ='N', then only eigenvalues are computed.

If *jobz* ='V', then eigenvalues and eigenvectors are computed.

range (global) CHARACTER*1. Must be 'A', 'V', or 'I'.

If *range* = 'A', all eigenvalues will be found.

If *range* = 'V', all eigenvalues in the half-open interval [*vl*, *vu*] will be found.

If *range* = 'I', the eigenvalues with indices *il* through *iu* will be found.

uplo (global) CHARACTER*1. Must be 'U' or 'L'.

Specifies whether the upper or lower triangular part of the symmetric matrix *A* is stored:

If *uplo* = 'U', *a* stores the upper triangular part of *A*.

If *uplo* = 'L', *a* stores the lower triangular part of *A*.

n (global) INTEGER. The number of rows and columns of the matrix *A* (*n* ≥ 0).

a (local). REAL for pssyevx

DOUBLE PRECISION for pdsyevx.

Block cyclic array of global size (*n*, *n*) and local size (*lld_a*, *LOCc*(*ja*+*n*-1)). On entry, the symmetric matrix *A*.

If *uplo* = 'U', only the upper triangular part of *A* is used to define the elements of the symmetric matrix.

If *uplo* = 'L', only the lower triangular part of *A* is used to define the elements of the symmetric matrix.

ia, *ja* (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

vl, *vu* (global)

REAL for pssyevx

DOUBLE PRECISION for pdsyevx.

If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; *vl* ≤ *vu*. Not referenced if *range* = 'A' or 'I'.

il, *iu* (global) INTEGER.

If *range* ='I', the indices of the smallest and largest eigenvalues to be returned.

Constraints: *il* ≥ 1

min(*il*,*n*) ≤ *iu* ≤ *n*

Not referenced if *range* = 'A' or 'V'.

abstol (global).REAL for pssyevx

DOUBLE PRECISION for pdsyevx.

If *jobz*='V', setting *abstol* to p?lamch(*context*, 'U') yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [*a*, *b*] of width less than or equal to

abstol + *eps* * max(|*a*|,|*b*|),

where *eps* is the machine precision. If *abstol* is less than or equal to zero, then *eps**norm(T) will be used in its place, where norm(T) is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form.

Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold 2*p?lamch('S') not zero. If this routine returns with (mod(*info*,2) ≠ 0) or (mod(*info*/8,2) ≠ 0)), indicating that some eigenvalues or eigenvectors did not converge, try setting *abstol* to 2*p?lamch('S').

orfac

(global).REAL for pssyevx

DOUBLE PRECISION for pdsyevx.

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within *tol=orfac*norm(*A*) of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0e-3 is used if *orfac* is negative. *orfac* should be identical on all processes.

iz, *jz*

(global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*. *descz*(*ctxt_*) must equal *desca*(*ctxt_*).

work

(local)

REAL for pssyevx.

DOUBLE PRECISION for pdsyevx.

Array of size *lwork*.

lwork

(local) INTEGER. The size of the array *work*.

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then *lwork* ≥ 5*n* + max(5*nn*, NB*(*np*0 + 1)).

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

lwork ≥ 5*n* + max(5*nn*, *np*0*mq*0 + 2*NB*NB) + iceil(*neig*, NPROW*NPCOL)**nn*

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following to *lwork*:

(*clustersize*-1)**n*,

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

{*w*(*k*),..., *w*(*k*+*clustersize*-1)|*w*(*j*+1) ≤ *w*(*j*)) + *orfac**2*norm(*A*)},

where

neig = number of eigenvectors requested

nb = *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*);

nn = max(*n*, *nb*, 2);

desca(*rsrc_*) = *desca*(*nb_*) = *descz*(*rsrc_*) = *descz*(*csrc_*) = 0;

*np*0 = numroc(*nn*, *nb*, 0, 0, NPROW);

*mq*0 = numroc(max(*neig*, *nb*, 2), *nb*, 0, 0, NPCOL)

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*)

If *lwork* is too small to guarantee orthogonality, p?syevx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, p?sygvx computes the eigenvalues and as many eigenvectors as possible.

Relationship between workspace, orthogonality & performance:

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

lwork ≥ max(*lwork*, 5**n* + *nsytrd_lwopt*),

where *lwork*, as defined previously, depends upon the number of eigenvectors requested, and

nsytrd_lwopt = *n* + 2*(*anb*+1)*(4**nps*+2) + (*nps* + 3)**nps;*

anb = pjlaenv(*desca*(*ctxt_*), 3, 'p?syttrd', 'L', 0, 0, 0, 0);

sqnpc = int(*sqrt*(*dble*(NPROW * NPCOL)));

nps = max(numroc(*n*, 1, 0, 0, *sqnpc*), 2**anb*);

numroc is a ScaLAPACK tool functions;

pjlaenv is a ScaLAPACK environmental inquiry function

MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

For large n, no extra workspace is needed, however the biggest boost in performance comes for small n, so it is wise to provide the extra workspace (typically less than a megabyte per process).

If *clustersize* > *n*/*sqrt*(NPROW*NPCOL), then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, *clustersize* = *n*-1) p?stein will perform no better than ?stein on single processor.

For *clustersize* = *n*/*sqrt*(NPROW*NPCOL) reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For *clustersize*>*n*/*sqrt*(NPROW*NPCOL) execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.

iwork (local) INTEGER. Workspace array.

liwork (local) INTEGER, size of *iwork*. *liwork* ≥ 6**nnp*

Where: *nnp* = max(*n*, NPROW*NPCOL + 1, 4)

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a On exit, the lower triangle (if *uplo* = 'L') or the upper triangle (if *uplo* = 'U')of *A*, including the diagonal, is overwritten.

m (global) INTEGER. The total number of eigenvalues found; 0 ≤ *m* ≤ *n*.

nz (global) INTEGER. Total number of eigenvectors computed. 0 ≤ *nz* ≤ *m*.

The number of columns of *z* that are filled.

If *jobz* ≠ 'V', *nz* is not referenced.

If *jobz* = 'V', *nz* = *m* unless the user supplies insufficient space and p?syevx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in *z* (*m*≤*descz*(*n*_)) and sufficient workspace to compute them. (See *lwork*). p?syevx is always able to detect insufficient space without computation unless *range* = 'V'.

w (global).REAL for pssyevx

DOUBLE PRECISION for pdsyevx.

Array of size *n*. The first *m* elements contain the selected eigenvalues in ascending order.

z (local).REAL for pssyevx

DOUBLE PRECISION for pdsyevx.

Array, global size (*n*, *n*), local size `(lld_z, LOCc(jz+n-1))`.

If `jobz = 'V'`, then on normal exit the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If `jobz = 'N'`, then *z* is not referenced.

work(1)

On exit, returns workspace adequate workspace to allow optimal performance.

iwork(1)

On return, *iwork*(1) contains the amount of integer workspace required.

ifail

(global)INTEGER.

Array of size *n*.

If `jobz = 'V'`, then on normal exit, the first *m* elements of *ifail* are zero. If `(mod(info,2) ≠ 0)` on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.

If `jobz = 'N'`, then *ifail* is not referenced.

iclustr

(global) INTEGER. Array of size `(2*NPROW*NPCOL)`

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2**i*-1) to *iclustr*(2**i*), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr*() is a zero terminated array. *iclustr*(2**k*) ≠ 0 and *iclustr*(2**k*+1) = 0 if and only if *k* is the number of clusters.

iclustr is not referenced if `jobz = 'N'`.

gap

(global)

REAL for pssyevx

DOUBLE PRECISION for pdsyevx.

Array of size NPROW*NPCOL

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*th cluster may be as high as `(C*n)/gap(i)` where *C* is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info*> 0: if (mod(*info*,2)≠0), then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure *abstol*=2.0*p?lamch('U').

If (mod(*info*/2,2)≠0), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace.The indices of the clusters are stored in the array *iclustr*.

If (mod(*info*/4,2)≠0), then space limit prevented p?syevxf rom computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If (mod(*info*/8,2)≠0), then p?stebz failed to compute eigenvalues. Ensure *abstol*=2.0*p?lamch('U').

NOTE
mod(*x*,*y*) is the integer remainder of *x*/*y*.

p?heev
Computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix.

Syntax
```
call pcheev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, rwork, lrwork, info)
call pzheev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, rwork, lrwork, info)
```

Include Files

Description
The p?heev routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix *A* by calling the recommended sequence of ScaLAPACK routines. The routine assumes a homogeneous system and makes spot checks of the consistency of the eigenvalues across the different processes. A heterogeneous system may return incorrect results without any error messages.

Input Parameters
np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz (global) CHARACTER*1. Must be 'N' or 'V'.

Specifies if it is necessary to compute the eigenvectors:

If *jobz* = 'N', then only eigenvalues are computed.

If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

uplo (global) CHARACTER*1. Must be 'U' or 'L'.

Specifies whether the upper or lower triangular part of the Hermitian matrix *A* is stored:

If *uplo* = 'U', *a* stores the upper triangular part of *A*.

If *uplo* = 'L', *a* stores the lower triangular part of *A*.

n (global) INTEGER. The number of rows and columns of the matrix *A*(*n*≥ 0).

a (local).

COMPLEX for pcheev

DOUBLE COMPLEX for pzheev.

Block cyclic array of global size (*n*, *n*) and local size (*lld_a*, *LOCc*(*ja* +*n*-1)). On entry, the Hermitian matrix *A*.

If *uplo* = 'U', only the upper triangular part of *A* is used to define the elements of the Hermitian matrix.

If *uplo* = 'L', only the lower triangular part of *A* is used to define the elements of the Hermitian matrix.

ia, *ja* (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*. If *desca*(*ctxt_*) is incorrect, p?heev cannot guarantee correct error reporting.

iz, *jz* (global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*. *descz*(*ctxt_*) must equal *desca*(*ctxt_*).

work (local).

COMPLEX for pcheev

DOUBLE COMPLEX for pzheev.

Array of size *lwork*.

lwork (local) INTEGER. The size of the array *work*.

If only eigenvalues are requested (*jobz* = 'N'):

lwork≥max(*nb**(*np*0 + 1), 3) + 3**n*

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required:

lwork≥ (*np*0+*nq*0+*nb*)**nb* + 3**n* + n^2

with *nb* = *desca*(*mb_*) = *desca*(*nb_*) = *nb* = *descz*(*mb_*) = *descz*(*nb_*)

*np*0 = numroc(*nn*, *nb*, 0, 0, NPROW).

*nq*0 = numroc(max(*n*, *nb*, 2), *nb*, 0, 0, NPCOL).

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by pxerbla.

rwork

(local).

REAL for pcheev

DOUBLE PRECISION for pzheev.

Workspace array of size *lrwork*.

lrwork

(local) INTEGER. The size of the array *rwork*.

See below for definitions of variables used to define *lrwork*.

If no eigenvectors are requested (*jobz* = 'N'), then *lrwork*≥ 2*n.

If eigenvectors are requested (*jobz* = 'V'), then *lrwork*≥ 2*n + 2*n-2.

If *lrwork* = -1, then *lrwork* is global input and a workspace query is assumed; the routine only calculates the minimum size required for the *rwork* array. The required workspace is returned as the first element of *rwork*, and no error message is issued by pxerbla.

Output Parameters

a

On exit, the lower triangle (if *uplo* = 'L'), or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

w

(global).

REAL for pcheev

DOUBLE PRECISION for pzheev.

Array of size *n*. The first *m* elements contain the selected eigenvalues in ascending order.

z

(local).

COMPLEX for pcheev

DOUBLE COMPLEX for pzheev.

Array, global size (*n*, *n*), local size (*lld_z*, *LOCc*(*jz*+*n*-1)).

If *jobz* ='V', then on normal exit the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If *jobz* = 'N', then *z* is not referenced.

work(1)

On exit, returns adequate workspace to allow optimal performance.

If *jobz* ='N', then *work*(1) = minimal workspace only for eigenvalues.

If *jobz* ='V', then *work*(1) = minimal workspace required to generate all the eigenvectors.

rwork(1) (local)

COMPLEX for pcheev

DOUBLE COMPLEX for pzheev.

On output, *rwork*(1) returns workspace required to guarantee completion.

info (global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*). If the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info*> 0:

If *info* = 1 through *n*, the *i*-th eigenvalue did not converge in ?steqr2 after a total of 30**n* iterations.

If *info* = *n*+1, then p?heev detected heterogeneity, and the accuracy of the results cannot be guaranteed.

p?heevd

Computes all eigenvalues and eigenvectors of a complex Hermitian matrix by using a divide and conquer algorithm.

Syntax

```
call pcheevd(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, info)
```

```
call pzheevd(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, info)
```

Include Files

Description

The p?heevd routine computes all eigenvalues and eigenvectors of a complex Hermitian matrix *A* by using a divide and conquer algorithm.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz (global) CHARACTER*1. Must be 'N' or 'V'.

Specifies if it is necessary to compute the eigenvectors:

If *jobz* = 'N', then only eigenvalues are computed.

If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

uplo (global) CHARACTER*1. Must be 'U' or 'L'.

Specifies whether the upper or lower triangular part of the Hermitian matrix *A* is stored:

If *uplo* = 'U', *a* stores the upper triangular part of *A*.

If *uplo* = 'L', *a* stores the lower triangular part of *A*.

n (global) INTEGER. The number of rows and columns of the matrix *A* (*n*≥ 0).

a (local).

COMPLEX for pcheevd

DOUBLE COMPLEX for pzheevd.

Block cyclic array of global size (*n*, *n*) and local size (*lld_a*, *LOCc*(*ja*+*n*-1)). On entry, the Hermitian matrix *A*.

If *uplo* = 'U', only the upper triangular part of *A* is used to define the elements of the Hermitian matrix.

If *uplo* = 'L', only the lower triangular part of *A* is used to define the elements of the Hermitian matrix.

ia, *ja* (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*. If *desca*(*ctxt_*) is incorrect, p?heevd cannot guarantee correct error reporting.

iz, *jz* (global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*. *descz*(*ctxt_*) must equal *desca*(*ctxt_*).

work (local).

COMPLEX for pcheevd

DOUBLE COMPLEX for pzheevd.

Array of size *lwork*.

lwork (local) INTEGER. The size of the array *work*.

If eigenvalues are requested:

lwork = *n* + (*nb*0 + *mq*0 + *nb*)**nb*

with *np*0 = numroc(max(*n*, *nb*, 2), *nb*, 0, 0, NPROW)

*mq*0 = numroc(max(*n*, *nb*, 2), *nb*, 0, 0, NPCOL)

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by pxerbla.

rwork (local).

REAL for pcheevd

DOUBLE PRECISION for pzheevd.

Workspace array of size *lrwork*.

lrwork (local) INTEGER. The size of the array *rwork*.

lrwork≥ 1 + 9*n + 3*np*nq,

with *np* = numroc(*n*, *nb*, *myrow*, *iarow*, NPROW)

nq = numroc(*n*, *nb*, *mycol*, *iacol*, NPCOL)

iwork (local) INTEGER. Workspace array of size *liwork*.

liwork (local) INTEGER , size of *iwork*.

liwork = 7*n + 8*npcol + 2.

Output Parameters

a On exit, the lower triangle (if *uplo* = 'L'), or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

w (global).

REAL for pcheevd

DOUBLE PRECISION for pzheevd.

Array of size *n*. If *info* = 0, *w* contains the eigenvalues in the ascending order.

z (local).

COMPLEX for pcheevd

DOUBLE COMPLEX for pzheevd.

Array, global size (*n*, *n*), local size (*lld_z*, *LOCc*(*jz*+*n*-1)).

The *z* parameter contains the orthonormal eigenvectors of the matrix *A*.

work(1) On exit, returns adequate workspace to allow optimal performance.

rwork(1) (local)

COMPLEX for pcheevd

DOUBLE COMPLEX for pzheevd.

On output, *rwork*(1) returns workspace required to guarantee completion.

iwork(1) (local).

On return, *iwork*(1) contains the amount of integer workspace required.

info (global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*). If the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info*> 0:

If *info* = 1 through *n*, the *i*-th eigenvalue did not converge.

p?heevr

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix using Relatively Robust Representation.

Syntax

```
call pcheevr( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, m, nz, w, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, info )
```

```
call pzheevr( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, m, nz, w, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, info )
```

Include Files

Description

p?heevr computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix *A* distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK routines.

First, the matrix *A* is reduced to complex Hermitian tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in *w*. The eigenvector matrix *Z* is stored in 2D block-cyclic format distributed over all processors.

Input Parameters

jobz

(global) CHARACTER*1

Specifies whether or not to compute the eigenvectors:

= 'N': Compute eigenvalues only.

= 'V': Compute eigenvalues and eigenvectors.

range

(global) CHARACTER*1

= 'A': all eigenvalues will be found.

= 'V': all eigenvalues in the interval [*vl*,*vu*] will be found.

= 'I': the *il*-th through *iu*-th eigenvalues will be found.

uplo (global) CHARACTER*1

Specifies whether the upper or lower triangular part of the Hermitian matrix *A* is stored:

= 'U': Upper triangular

= 'L': Lower triangular

n (global) INTEGER

The number of rows and columns of the matrix *A*. $n \geq 0$

a COMPLEX for pcheevr

COMPLEX*16 for pzheevr

Block-cyclic array, global size (*n*, *n*), local size (*lld_a*, $LOC_c(ja+n-1)$)

Contains the local pieces of the Hermitian distributed matrix *A*. If *uplo* = 'U', only the upper triangular part of *a* is used to define the elements of the Hermitian matrix. If *uplo* = 'L', only the lower triangular part of *a* is used to define the elements of the Hermitian matrix.

ia (global) INTEGER

Global row index in the global matrix *A* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

ja (global) INTEGER

Global column index in the global matrix *A* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

desca (global and local) INTEGER array of size *dlen_*. (The ScaLAPACK descriptor length is *dlen_* = 9.)

The array descriptor for the distributed matrix *a*. The descriptor stores details about the 2D block-cyclic storage, see the notes below. If *desca* is incorrect, p?heevr cannot work correctly.

Also note the array alignment requirements specified below

vl REAL for pcheevr

DOUBLE PRECISION for pzheevr

(global)

If *range*='V', the lower bound of the interval to be searched for eigenvalues. Not referenced if *range* = 'A' or 'I'.

vu REAL for pcheevr

DOUBLE PRECISION for pzheevr

(global)

If *range*='V', the upper bound of the interval to be searched for eigenvalues. Not referenced if *range* = 'A' or 'I'.

il (global) INTEGER

If *range*='I', the index (from smallest to largest) of the smallest eigenvalue to be returned. *il*≥ 1.

Not referenced if *range* = 'A'.

iu

(global) INTEGER

If *range*='I', the index (from smallest to largest) of the largest eigenvalue to be returned. min(*il*,*n*) ≤*iu*≤*n*.

Not referenced if *range* = 'A'.

iz

(global) INTEGER

Global row index in the global matrix *Z* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

jz

(global) INTEGER

Global column index in the global matrix *Z* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

descz

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *z*. *descz*(*ctxt_*) must equal *desca*(*ctxt_*)

work

COMPLEX for pcheevr

COMPLEX*16 for pzheevr

(local workspace) array of size *lwork*

lwork

(local) INTEGER

Size of *work* array, must be at least 3.

If only eigenvalues are requested:

lwork≥*n* + max(*nb* * (*np00* + 1), *nb* * 3)

If eigenvectors are requested:

lwork≥*n* + (*np00* + *mq00* + *nb*) * *nb*

For definitions of *np00* and *mq00*, see *lrwork*.

For optimal performance, greater workspace is needed, i.e.

lwork≥ max(*lwork*, *nhetrd_lwork*)

Where *lwork* is as defined above, and

nhetrd_lwork = *n* + 2*(*anb*+1)*(4**nps*+2) + (*nps* + 1) * *nps*

ictxt = *desca*(*ctxt_*)

anb = pjlaenv(*ictxt*, 3, 'PCHETTRD', 'L', 0, 0, 0, 0)

sqnpc = sqrt(real(*nprow* * *npcol*))

nps = max(numroc(*n*, 1, 0, 0, *sqnpc*), 2**anb*)

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

rwork

REAL for pcheevr

DOUBLE PRECISION for pzheevr

(local workspace) array of size *lrwork*

lrwork

(local) INTEGER

Size of *rwork*, must be at least 3.

See below for definitions of variables used to define *lrwork*.

If no eigenvectors are requested (*jobz* = 'N') then

lrwork≥ 2 + 5 * *n* + max(12 * *n*, *nb* * (*np00* + 1))

If eigenvectors are requested (*jobz* = 'V') then the amount of workspace required is:

lrwork≥ 2 + 5 * *n* + max(18**n*, *np00* * *mq00* + 2 * *nb* * *nb*) +

(2 + iceil(*neig*, *nprow***npcol*))**n*

NOTE
iceil(*x*, *y*) is the ceiling of *x*/*y*.

Variable definitions:

neig = number of eigenvectors requested

nb = *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*)

nn = max(*n*, *nb*, 2)

desca(*rsrc_*) = *desca*(*csrc_*) = *descz*(*rsrc_*) = *descz*(*csrc_*) = 0

np00 = numroc(*nn*, *nb*, 0, 0, *nprow*)

mq00 = numroc(max(*neig*, *nb*, 2), *nb*, 0, 0, *npcol*)

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*), and *nprow* and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lrwork* = -1, then *lrwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla

iwork

(local workspace) INTEGER array of size *liwork*

liwork

(local) INTEGER

size of *iwork*

Let *nnp* = max(*n*, *nprow***npcol* + 1, 4). Then:

liwork≥ 12**nnp* + 2**n* when the eigenvectors are desired

liwork≥ 10**nnp* + 2**n* when only the eigenvalues have to be computed

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla

OUTPUT Parameters

a

The lower triangle (if *uplo*='L') or the upper triangle (if *uplo*='U') of *a*, including the diagonal, is destroyed.

m

(global) INTEGER

Total number of eigenvalues found. 0 ≤*m*≤*n*.

nz

(global) INTEGER

Total number of eigenvectors computed. 0 ≤*nz*≤*m*.

The number of columns of *z* that are filled.

If *jobz*≠ 'V', *nz* is not referenced.

If *jobz* = 'V', *nz* = *m*

w

REAL for pcheevr

DOUBLE PRECISION for pzheevr

(global) array of size *n*

On normal exit, the first *m* entries contain the selected eigenvalues in ascending order.

z

COMPLEX for pcheevr

COMPLEX*16 for pzheevr

(local) array, global size (*n*, *n*), local size (*lld_z*, LOC_c(*jz*+*n*-1))

If *jobz* = 'V', then on normal exit the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues.

If *jobz* = 'N', then *z* is not referenced.

work

work(1) returns workspace adequate workspace to allow optimal performance.

rwork

On return, *rwork*(1) contains the optimal amount of workspace required for efficient execution. if *jobz*='N' *rwork*(1) = optimal amount of workspace required to compute the eigenvalues. if *jobz*='V' *rwork*(1) = optimal amount of workspace required to compute eigenvalues and eigenvectors.

iwork

On return, *iwork*(1) contains the amount of integer workspace required.

info

(global) INTEGER

= 0: successful exit

< 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The distributed submatrices *a*(*ia*:*, *ja*:*) and *z*(*iz*:*iz*+*m*-1,*jz*:*jz*+*n*-1) must satisfy the following alignment properties:

1. Identical (quadratic) dimension: *desca*(*m_*) = *descz*(*m_*) = *desca*(*n_*) = *descz*(*n_*)
2. Quadratic conformal blocking: *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*), *desca*(*rsrc_*) = *descz*(*rsrc_*)
3. mod(*ia*-1, *mb_a*) = mod(*iz*-1, *mb_z*) = 0

NOTE
mod(*x*,*y*) is the integer remainder of *x*/*y*.

p?heevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

```
call pcheevx(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, ifail, iclustr, gap, info)
```

```
call pzheevx(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, ifail, iclustr, gap, info)
```

Include Files

Description

The p?heevx routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix *A* by calling the recommended sequence of ScaLAPACK routines. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz (global) CHARACTER*1. Must be 'N' or 'V'.

Specifies if it is necessary to compute the eigenvectors:

If *jobz* = 'N', then only eigenvalues are computed.

If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

range (global) CHARACTER*1. Must be 'A', 'V', or 'I'.

If *range* = 'A', all eigenvalues will be found.

If *range* = 'V', all eigenvalues in the half-open interval [*vl*, *vu*] will be found.

If *range* = 'I', the eigenvalues with indices *il* through *iu* will be found.

uplo (global) CHARACTER*1. Must be 'U' or 'L'.

Specifies whether the upper or lower triangular part of the Hermitian matrix *A* is stored:

If *uplo* = 'U', *a* stores the upper triangular part of *A*.

If *uplo* = 'L', *a* stores the lower triangular part of *A*.

n (global) INTEGER. The number of rows and columns of the matrix *A* (*n* ≥ 0).

a (local).

COMPLEX for pcheevx

DOUBLE COMPLEX for pzheevx.

Block cyclic array of global size (*n*, *n*) and local size (*lld_a*, *LOCc*(*ja*+*n*-1)). On entry, the Hermitian matrix *A*.

If *uplo* = 'U', only the upper triangular part of *A* is used to define the elements of the Hermitian matrix.

If *uplo* = 'L', only the lower triangular part of *A* is used to define the elements of the Hermitian matrix.

ia, *ja* (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*. If *desca*(*ctxt_*) is incorrect, p?heevx cannot guarantee correct error reporting.

vl, *vu* (global)

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; not referenced if *range* = 'A' or 'I'.

il, *iu* (global)

INTEGER. If *range* ='I', the indices of the smallest and largest eigenvalues to be returned.

Constraints:

il ≥ 1; min(*il*,*n*) ≤ *iu* ≤ *n*.

Not referenced if *range* = 'A' or 'V'.

abstol (global).

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

If *jobz*='V', setting *abstol* to p?lamch(*context*, 'U') yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [*a*, *b*] of width less than or equal to *abstol*+*eps**max(|*a*|,|*b*|), where *eps* is the machine precision. If *abstol* is less than or equal to zero, then *eps**norm(T) will be used in its place, where norm(T) is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form.

Eigenvalues are computed most accurately when *abstol* is set to twice the underflow threshold 2*p?lamch('S'), not zero. If this routine returns with ((mod(*info*,2)≠0).*or*.(mod(*info*/8,2)≠0)), indicating that some eigenvalues or eigenvectors did not converge, try setting *abstol* to 2*p?lamch('S').

NOTE
mod(*x*,*y*) is the integer remainder of *x*/*y*.

orfac (global). REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within *tol*=*orfac**norm(*A*) of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0e-3 is used if *orfac* is negative.

orfac should be identical on all processes.

iz, *jz* (global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*. *descz*(*ctxt_*) must equal *desca*(*ctxt_*).

work (local).

COMPLEX for pcheevx

DOUBLE COMPLEX for pzheevx.

Array of size *lwork*.

lwork (local) INTEGER. The size of the array *work*.

If only eigenvalues are requested:

lwork≥*n* + max(*nb**(*np*0 + 1), 3)

If eigenvectors are requested:

lwork≥*n* + (*np*0+*mq*0+*nb*)***nb*

with *nq*0 = numroc(*nn*, *nb*, 0, 0, NPCOL).

lwork≥ 5**n* + max(5**nn*, *np*0**mq*0+2**nb***nb*) + iceil(*neig*, NPROW*NPCOL)**nn*

For optimal performance, greater workspace is needed, that is

lwork≥max(*lwork*, *nhetrd_lwork*)

where *lwork* is as defined above, and *nhetrd_lwork* = *n* + 2*(*anb* +1)*(4**nps*+2) + (*nps*+1)**nps*

ictxt = *desca*(*ctxt_*)

anb = pjlaenv(*ictxt*, 3, 'pchettrd', 'L', 0, 0, 0, 0)

sqnpc = *sqrt*(*dble*(NPROW * NPCOL))

nps = max(numroc(*n*, 1, 0, 0, *sqnpc*), 2**anb*)

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.

rwork (local)

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Workspace array of size *lrwork*.

lrwork (local) INTEGER. The size of the array *work*.

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then *lrwork*≥ 5**nn*+4**n*.

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

lrwork≥ 4**n* + max(5**nn*, *np*0**mq*0+2**nb***nb*) + iceil(*neig*, NPROW*NPCOL)**nn*

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following values to *lrwork*:

(*clustersize*-1)**n*,

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

{*w*(*k*),..., *w*(*k*+*clustersize*-1)|*w*(*j*+1) ≤ *w*(*j*) +*orfac**2*norm(*A*)}.

Variable definitions:

neig = number of eigenvectors requested;

nb = *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*);

nn = max(*n*, NB, 2);

desca(*rsrc_*) = *desca*(*nb_*) = *descz*(*rsrc_*) = *descz*(*csrc_*) = 0;

*np*0 = numroc(*nn*, *nb*, 0, 0, NPROW);

*mq*0 = numroc(max(*neig*, *nb*, 2), *nb*, 0, 0, NPCOL);

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*)

When *lrwork* is too small:

If *lwork* is too small to guarantee orthogonality, p?heevx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues. If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned. Note that when *range*='V', p?heevx does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range*='V' and as long as *lwork* is large enough to allow p?heevx to compute the eigenvalues, p?heevx will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality and performance:

If *clustersize* ≥ *n*/*sqrt*(NPROW*NPCOL), then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, *clustersize* = *n*-1)p?stein will perform no better than ?stein on 1 processor.

For *clustersize* = *n*/*sqrt*(NPROW*NPCOL) reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For *clustersize*>*n*/*sqrt*(NPROW*NPCOL) execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.

iwork (local) INTEGER. Workspace array.

liwork (local) INTEGER, size of *iwork*.

liwork ≥ 6**nnp*

Where: *nnp* = max(*n*, NPROW*NPCOL+1, 4)

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a On exit, the lower triangle (if *uplo* = 'L'), or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

m (global) INTEGER. The total number of eigenvalues found; $0 \le m \le n$.

nz (global) INTEGER. Total number of eigenvectors computed. $0 \le nz \le m$.

The number of columns of *z* that are filled.

If *jobz* ≠ 'V', *nz* is not referenced.

If *jobz* = 'V', *nz* = *m* unless the user supplies insufficient space and p?heevx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in *z* (*m*≤*descz*(*n_*)) and sufficient workspace to compute them. (See *lwork*). p?heevx is always able to detect insufficient space without computation unless *range*='V'.

w (global).

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Array of size *n*. The first *m* elements contain the selected eigenvalues in ascending order.

z (local).

COMPLEX for pcheevx

DOUBLE COMPLEX for pzheevx.

Array, global size (*n*, *n*), local size (*lld_z*, *LOCc*(*jz*+*n*-1)).

If *jobz* ='V', then on normal exit the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If *jobz* = 'N', then *z* is not referenced.

work(1) On exit, returns adequate workspace to allow optimal performance.

rwork (local).

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Array of size *lrwork*. On return, *rwork*(1) contains the optimal amount of workspace required for efficient execution.

If *jobz*='N'*rwork*(1) = optimal amount of workspace required to compute eigenvalues efficiently.

If *jobz*='V'*rwork*(1) = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If *range*='V', it is assumed that all eigenvectors may be required.

iwork(1) (local)

On return, *iwork*(1) contains the amount of integer workspace required.

ifail (global) INTEGER.

Array of size *n*.

If *jobz* ='V', then on normal exit, the first *m* elements of *ifail* are zero. If (mod(*info*,2)≠0) on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.

If *jobz* = 'N', then *ifail* is not referenced.

iclustr

(global) INTEGER.

Array of size 2*NPROW*NPCOL.

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2*i*-1) to *iclustr*(2*i*), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr*() is a zero terminated array. (*iclustr*(2**k*)≠0 and *iclustr*(2**k*+1)=0) if and only if *k* is the number of clusters. *iclustr* is not referenced if *jobz* = 'N'.

gap

(global)

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Array of size (NPROW*NPCOL)

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as (*C***n*)/ *gap*(*i*) where *C* is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*). If the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info*> 0:

If (mod(*info*,2)≠0), then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure *abstol*=2.0*p?lamch('U')

If (mod(*info*/2,2)≠0), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace.The indices of the clusters are stored in the array *iclustr*.

If (mod(*info*/4,2)≠0), then space limit prevented p?syevx from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If (mod(*info*/8,2)≠0), then p?stebz failed to compute eigenvalues. Ensure *abstol*=2.0*p?lamch('U').

p?gesvd

Computes the singular value decomposition of a general matrix, optionally computing the left and/or right singular vectors.

Syntax

```
call psgesvd(jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt, ivt, jvt, descvt, work, lwork, info)
call pdgesvd(jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt, ivt, jvt, descvt, work, lwork, info)
call pcgesvd(jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt, ivt, jvt, descvt, work, lwork, rwork, info)
call pzgesvd(jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt, ivt, jvt, descvt, work, lwork, rwork, info)
```

Include Files

Description

The p?gesvd routine computes the singular value decomposition (SVD) of an *m*-by-*n* matrix *A*, optionally computing the left and/or right singular vectors. The SVD is written

$A = U*\Sigma*V^T$,

where Σ is an *m*-by-*n* matrix that is zero except for its min(*m*, *n*) diagonal elements, *U* is an *m*-by-*m* orthogonal matrix, and *V* is an *n*-by-*n* orthogonal matrix. The diagonal elements of Σ are the singular values of *A* and the columns of *U* and *V* are the corresponding right and left singular vectors, respectively. The singular values are returned in array *s* in decreasing order and only the first min(*m*,*n*) columns of *U* and rows of $vt = V^T$ are computed.

NOTE
The distributed submatrix sub(*A*) must verify certain alignment properties. These expressions must be true:

- *mb_a* = *nb_a* = *nb*
- *iroffa* = *icoffa*

where:

- *iroffa* = mod(*ia*-1, *nb*)
- *icoffa* = mod(*ja*-1, *nb*)

Input Parameters

mp = number of local rows in *A* and *U*

nq = number of local columns in *A* and *VT*

size = min(*m*, *n*)

sizeq = number of local columns in *U*

sizep = number of local rows in *VT*

jobu	(global) CHARACTER*1. Specifies options for computing all or part of the matrix *U*. If *jobu* = 'V', the first *size* columns of *U* (the left singular vectors) are returned in the array *u*; If *jobu* ='N', no columns of *U* (no left singular vectors)are computed.
jobvt	(global) CHARACTER*1. Specifies options for computing all or part of the matrix V^T. If *jobvt* = 'V', the first *size* rows of V^T (the right singular vectors) are returned in the array *vt*; If *jobvt* = 'N', no rows of V^T(no right singular vectors) are computed.
m	(global) INTEGER. The number of rows of the matrix *A* (*m*≥ 0).
n	(global) INTEGER. The number of columns in *A* (*n*≥ 0).
a	(local). REAL for psgesvd DOUBLE PRECISION for pdgesvd COMPLEX for pcgesvd COMPLEX*16 for pzgesvd Block cyclic array, global size (*m*, *n*), local size (*mp*, *nq*).
ia, *ja*	(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.
desca	(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.
iu, *ju*	(global) INTEGER. The row and column indices in the global matrix *U* indicating the first row and the first column of the submatrix *U*, respectively.
descu	(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *U*.
ivt, *jvt*	(global) INTEGER. The row and column indices in the global matrix *VT* indicating the first row and the first column of the submatrix *VT*, respectively.
descvt	(global and local)INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *VT*.
work	(local).REAL for psgesvd

DOUBLE PRECISION for pdgesvd

COMPLEX for pcgesvd

COMPLEX*16 for pzgesvd

Workspace array of size *lwork*

lwork (local) INTEGER. The size of the array *work*;

lwork > 2 + 6*sizeb + max(*watobd*, *wbdtosvd*),

where *sizeb* = max(*m*, *n*), and *watobd* and *wbdtosvd* refer, respectively, to the workspace required to bidiagonalize the matrix *A* and to go from the bidiagonal matrix to the singular value decomposition *USVT*.

For *watobd*, the following holds:

watobd = max(max(*wp?lange*,*wp?gebrd*), max(*wp?lared2d*, *wp?lared1d*)),

where *wp?lange*, *wp?lared1d*, *wp?lared2d*, *wp?gebrd* are the workspaces required respectively for the subprograms p?lange, p?lared1d, p?lared2d, p?gebrd. Using the standard notation

mp = numroc(*m*, *mb*, MYROW, *desca*(*ctxt_*), NPROW),

nq = numroc(*n*, *nb*, MYCOL, *desca*(*lld_*), NPCOL),

the workspaces required for the above subprograms are

wp?lange = *mp*,

wp?lared1d = *nq*0,

wp?lared2d = *mp*0,

wp?gebrd = *nb**(*mp* + *nq* + 1) + *nq*,

where *nq*0 and *mp*0 refer, respectively, to the values obtained at MYCOL = 0 and MYROW = 0. In general, the upper limit for the workspace is given by a workspace required on processor (0,0):

watobd ≤ *nb**(*mp*0 + *nq*0 + 1) + *nq*0.

In case of a homogeneous process grid this upper limit can be used as an estimate of the minimum workspace for every processor.

For *wbdtosvd*, the following holds:

wbdtosvd = *size**(*wantu***nru* + *wantvt***ncvt*) + max(*w?bdsqr*, max(*wantu***wp?ormbrqln*, *wantvt***wp?ormbrprt*)),

where

wantu(*wantvt*) = 1, if left/right singular vectors are wanted, and *wantu*(*wantvt*) = 0, otherwise. *w?bdsqr*, *wp?ormbrqln*, and *wp?ormbrprt* refer respectively to the workspace required for the subprograms ?bdsqr, p?ormbr(*qln*), and p?ormbr(*prt*), where *qln* and *prt* are the values of the arguments *vect*, *side*, and *trans* in the call to p?ormbr. *nru* is equal to the local number of rows of the matrix *U* when distributed 1-dimensional "column" of processes. Analogously, *ncvt* is equal to the local number of columns of the matrix *VT* when distributed across 1-dimensional "row" of processes. Calling the LAPACK procedure ?bdsqr requires

w?bdsqr = max(1, 2**size* + (2**size* - 4)* max(*wantu*, *wantvt*))

on every processor. Finally,

wp?ormbrqln = max((*nb**(*nb*-1))/2, (*sizeq*+*mp*)**nb*)+*nb***nb*,

wp?ormbrprt = max((*mb**(*mb*-1))/2, (*sizep*+*nq*)**mb*)+*mb***mb*,

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum size for the work array. The required workspace is returned as the first element of *work* and no error message is issued by pxerbla.

rwork

REAL for pcgesvd

DOUBLE PRECISION for pzgesvd

Workspace array of size 1 + 4**sizeb*. Not used for psgesvd and pdgesvd.

Output Parameters

a

On exit, the contents of *a* are destroyed.

s

(global). REAL for psgesvd and pcgesvd

DOUBLE PRECISION for pdgesvd and pzgesvd

Array of size *size*.

Contains the singular values of *A* sorted so that *s*(i) ≥*s*(i+1).

u

(local). REAL for psgesvd

DOUBLE PRECISION for pdgesvd

COMPLEX for pcgesvd

COMPLEX*16 for pzgesvd

local size (*mp*, *sizeq*), global size (*m*, *size*)

If *jobu* = 'V', *u* contains the first min(*m*, *n*) columns of *U*.

If *jobu* = 'N' or 'O', *u* is not referenced.

vt

(local). REAL for psgesvd

DOUBLE PRECISION for pdgesvd

COMPLEX for pcgesvd

COMPLEX*16 for pzgesvd

local size (*sizep*, *nq*), global size (*size*, *n*)

If *jobvt* = 'V', *vt* contains the first *size* rows of V^Tif *jobu* = 'N', *vt* is not referenced.

work

On exit, if *info* = 0, then *work*(1) returns the required minimal size of *lwork*.

rwork

On exit, if *info* = 0, then *rwork*(1) returns the required size of *rwork*.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0, If *info* = -*i*, the *i*th parameter had an illegal value.

If *info* > 0 *i*, then if ?bdsqr did not converge,

If *info* = min(*m*,*n*) + 1, then p?gesvd has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from p?gesvd cannot be guaranteed.

p?sygvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem.

Syntax

call pssygvx(*ibtype*, *jobz*, *range*, *uplo*, *n*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *vl*, *vu*, *il*, *iu*, *abstol*, *m*, *nz*, *w*, *orfac*, *z*, *iz*, *jz*, *descz*, *work*, *lwork*, *iwork*, *liwork*, *ifail*, *iclustr*, *gap*, *info*)

call pdsygvx(*ibtype*, *jobz*, *range*, *uplo*, *n*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *vl*, *vu*, *il*, *iu*, *abstol*, *m*, *nz*, *w*, *orfac*, *z*, *iz*, *jz*, *descz*, *work*, *lwork*, *iwork*, *liwork*, *ifail*, *iclustr*, *gap*, *info*)

Include Files

Description

The p?sygvxroutine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

sub(*A*)**x* = λ*sub(*B*)**x*, sub(*A*) sub(*B*)**x* = λ**x*, or sub(*B*)*sub(*A*)**x* = λ**x*.

Here *x* denotes eigen vectors, λ (*lambda*) denotes eigenvalues, sub(*A*) denoting A(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) is assumed to symmetric, and sub(*B*) denoting *B*(*ib*:*ib*+*n*-1, *jb*:*jb*+*n*-1) is also positive definite.

Input Parameters

ibtype

(global) INTEGER. Must be 1 or 2 or 3.

Specifies the problem type to be solved:

If *ibtype* = 1, the problem type is sub(*A*)**x* = *lambda**sub(*B*)**x*;

If *ibtype* = 2, the problem type is sub(*A*)*sub(*B*)**x* = *lambda***x*;

If *ibtype* = 3, the problem type is sub(*B*)*sub(*A*)**x* = *lambda***x*.

jobz

(global) CHARACTER*1. Must be 'N' or 'V'.

If *jobz* ='N', then compute eigenvalues only.

If *jobz* ='V', then compute eigenvalues and eigenvectors.

range (global) CHARACTER*1. Must be 'A' or 'V' or 'I'.

If *range* = 'A', the routine computes all eigenvalues.

If *range* = 'V', the routine computes eigenvalues in the interval: [*vl*, *vu*]

If *range* = 'I', the routine computes eigenvalues with indices *il* through *iu*.

uplo (global) CHARACTER*1. Must be 'U' or 'L'.

If *uplo* = 'U', arrays *a* and *b* store the upper triangles of sub(*A*) and sub (*B*);

If *uplo* = 'L', arrays *a* and *b* store the lower triangles of sub(*A*) and sub (*B*).

n (global) INTEGER. The order of the matrices sub(*A*) and sub (*B*), $n \geq 0$.

a (local)

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)). On entry, this array contains the local pieces of the *n*-by-*n* symmetric distributed matrix sub(*A*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*A*) contains the upper triangular part of the matrix.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the matrix.

ia, *ja* (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*. If *desca*(*ctxt_*) is incorrect, p?sygvx cannot guarantee correct error reporting.

b (local). REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

Pointer into the local memory to an array of size (*lld_b*, *LOCc*(*jb*+*n*-1)). On entry, this array contains the local pieces of the *n*-by-*n* symmetric distributed matrix sub(*B*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*B*) contains the upper triangular part of the matrix.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the matrix.

ib, *jb* (global) INTEGER. The row and column indices in the global matrix *B* indicating the first row and the first column of the submatrix *B*, respectively.

descb (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*. *descb*(*ctxt_*) must be equal to *desca*(*ctxt_*).

vl, *vu* (global)

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, *iu* (global)

INTEGER.

If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1$, $\min(il, n) \leq iu \leq n$

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol (global)

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

If *jobz*='V', setting *abstol* to p?lamch(*context*, 'U') yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [*a*,*b*] of width less than or equal to

abstol + *eps**max(|*a*|,|*b*|),

where *eps* is the machine precision. If *abstol* is less than or equal to zero, then *eps**norm(T) will be used in its place, where norm(T) is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form.

Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold 2*p?lamch('S') not zero. If this routine returns with ((mod(*info*,2)≠0) or (*mod*(*info*/8,2)≠0)), indicating that some eigenvalues or eigenvectors did not converge, try setting *abstol* to 2*p?lamch('S').

NOTE
mod(*x*,*y*) is the integer remainder of *x*/*y*.

orfac (global).

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within *tol*=*orfac**norm(*A*) of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be

reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0e-3 is used if *orfac* is negative. *orfac* should be identical on all processes.

iz, *jz*

(global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*. *descz*(*ctxt_*) must equal *desca*(*ctxt_*).

work

(local)

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

Workspace array of size *lwork*

lwork

(local) INTEGER.

Size of the array *work*. See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then *lwork* ≥ 5**n* + max(5**nn*, NB*(*np*0 + 1)).

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

lwork ≥ 5**n* + max(5**nn*, *np*0**mq*0 + 2**nb***nb*) + iceil(*neig*, NPROW*NPCOL)**nn*.

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality at the cost of potentially poor performance you should add the following to *lwork*:

(*clustersize*-1)**n*,

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

{*w*(*k*),..., *w*(*k*+*clustersize*-1)|*w*(*j*+1) ≤ *w*(*j*) + *orfac**2*norm*(*A*)}

Variable definitions:

neig = number of eigenvectors requested,

nb = *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*),

nn = max(*n*, *nb*, 2),

desca(*rsrc_*) = *desca*(*nb_*) = *descz*(*rsrc_*) = *descz*(*csrc_*) = 0,

*np*0 = numroc(*nn*, *nb*, 0, 0, NPROW),

*mq*0 = numroc(max(*neig*, *nb*, 2), *nb*, 0, 0, NPCOL)

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*)

If *lwork* is too small to guarantee orthogonality, p?syevx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, p?sygvx computes the eigenvalues and as many eigenvectors as possible.

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

lwork ≥ max(*lwork*, 5*n* + *nsytrd_lwopt*, *nsygst_lwopt*), where

lwork, as defined previously, depends upon the number of eigenvectors requested, and

nsytrd_lwopt = *n* + 2*(*anb*+1)*(4**nps*+2) + (*nps*+3)**nps*

nsygst_lwopt = 2**np*0**nb* + *nq*0**nb* + *nb***nb*

anb = pjlaenv(*desca*(*ctxt_*), 3, p?syttrd ', 'L', 0, 0, 0, 0)

sqnpc = int(*sqrt*(*dble*(NPROW * NPCOL)))

nps = max(numroc(*n*, 1, 0, 0, *sqnpc*), 2**anb*)

NB = *desca*(*mb_*)

*np*0 = numroc(*n*, *nb*, 0, 0, NPROW)

*nq*0 = numroc(*n*, *nb*, 0, 0, NPCOL)

numroc is a ScaLAPACK tool functions;

pjlaenv is a ScaLAPACK environmental inquiry function

MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

For large n, no extra workspace is needed, however the biggest boost in performance comes for small n, so it is wise to provide the extra workspace (typically less than a Megabyte per process).

If *clustersize* ≥ *n*/*sqrt*(NPROW*NPCOL), then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, *clustersize* = *n*-1) p?stein will perform no better than ?stein on a single processor.

For *clustersize* = *n*/*sqrt*(NPROW*NPCOL) reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For *clustersize*>*n*/*sqrt*(NPROW*NPCOL) execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.

iwork (local) INTEGER. Workspace array.

liwork (local) INTEGER , size of *iwork*.

liwork ≥ 6*nnp

Where:

nnp = max(*n*, NPROW*NPCOL + 1, 4)

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a On exit,

If *jobz* = 'V', and if *info* = 0, sub(*A*) contains the distributed matrix *Z* of eigenvectors. The eigenvectors are normalized as follows:

for *ibtype* = 1 or 2, Z^T*sub(*B*)**Z* = *i*;

for *ibtype* = 3, Z^T*inv(sub(*B*))**Z* = *i*.

If *jobz* = 'N', then on exit the upper triangle (if *uplo*='U') or the lower triangle (if *uplo*='L') of sub(*A*), including the diagonal, is destroyed.

b On exit, if *info* ≤ *n*, the part of sub(*B*) containing the matrix is overwritten by the triangular factor *U* or *L* from the Cholesky factorization sub(*B*) = U^T**U* or sub(*B*) = *L***L*^{T}.

m (global) INTEGER. The total number of eigenvalues found, 0 ≤ *m* ≤ *n*.

nz (global) INTEGER.

Total number of eigenvectors computed. 0 ≤ *nz* ≤ *m*. The number of columns of *z* that are filled.

If *jobz* ≠ 'V', *nz* is not referenced.

If *jobz* = 'V', *nz* = *m* unless the user supplies insufficient space and p?sygvx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in *z* (*m*≤*descz*(*n_*)) and sufficient workspace to compute them. (See *lwork* below.) p?sygvx is always able to detect insufficient space without computation unless *range*='V'.

w (global)

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

Array of size *n*. On normal exit, the first *m* entries contain the selected eigenvalues in ascending order.

z (local).

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

global size (*n*, *n*), local size `(lld_z, LOCc(jz+n-1))`.

If `jobz = 'V'`, then on normal exit the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If `jobz = 'N'`, then *z* is not referenced.

work

If *jobz*=`'N'` *work*`(1)` = optimal amount of workspace required to compute eigenvalues efficiently

If `jobz = 'V'` *work*`(1)` = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If *range*=`'V'`, it is assumed that all eigenvectors may be required.

ifail

(global) `INTEGER`.

Array of size *n*.

ifail provides additional information when *info*≠0

If `(mod(info/16,2)≠0)` then *ifail*`(1)` indicates the order of the smallest minor which is not positive definite. If `(mod(info,2)≠0)` on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.

If neither of the above error conditions hold and `jobz = 'V'`, then the first *m* elements of *ifail* are set to zero.

iclustr

(global) `INTEGER`.

Array of size `(2*NPROW*NPCOL)`. This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*`(2*i-1)` to *iclustr*`(2*i)`, could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr*`()` is a zero terminated array.

`(iclustr(2*k)≠0.and. iclustr(2*k+1)=0)` if and only if *k* is the number of clusters *iclustr* is not referenced if `jobz = 'N'`.

gap

(global)

`REAL` for `pssygvx`

`DOUBLE PRECISION` for `pdsygvx`.

Array of size `NPROW*NPCOL`. This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as `(C*n)/gap(i)`, where *C* is a small constant.

info

(global) `INTEGER`.

If `info = 0`, the execution is successful.

If *info* <0: the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info*> 0:

If (mod(*info*,2)≠0), then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If (mod(*info*,2,2)≠0), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If (mod(*info*/4,2)≠0), then space limit prevented p?sygvx from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If (mod(*info*/8,2)≠0), then p?stebz failed to compute eigenvalues.

If (mod(*info*/16,2)≠0), then *B* was not positive definite. *ifail(1)* indicates the order of the smallest minor which is not positive definite.

Include Files

Description

The p?hegvx routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

sub(*A*)**x* = λ*sub(*B*)**x*, sub(*A*)*sub(*B*)**x* = λ**x*, or sub(*B*)*sub(*A*)**x* = λ**x*.

Here sub (*A*) denoting *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) and sub(*B*) are assumed to be Hermitian and sub(*B*) denoting *B*(*ib*:*ib*+*n*-1, *jb*:*jb*+*n*-1) is also positive definite.

Input Parameters

ibtype

(global) INTEGER. Must be 1 or 2 or 3.

Specifies the problem type to be solved:

If *ibtype* = 1, the problem type is

sub(*A*)**x* = *lambda**sub(*B*)**x*;

If *ibtype* = 2, the problem type is

sub(*A*)*sub(*B*)**x* = *lambda***x*;

If *ibtype* = 3, the problem type is

sub(*B*)*sub(*A*)**x* = *lambda***x*.

jobz

(global) CHARACTER*1. Must be 'N' or 'V'.

If *jobz* ='N', then compute eigenvalues only.

If *jobz* ='V', then compute eigenvalues and eigenvectors.

range

(global) CHARACTER*1. Must be 'A' or 'V' or 'I'.

If *range* = 'A', the routine computes all eigenvalues.

If *range* = 'V', the routine computes eigenvalues in the interval: [*vl*, *vu*]

If *range* = 'I', the routine computes eigenvalues with indices *il* through *iu*.

uplo

(global) CHARACTER*1. Must be 'U' or 'L'.

If *uplo* = 'U', arrays *a* and *b* store the upper triangles of sub(*A*) and sub (*B*);

If *uplo* = 'L', arrays *a* and *b* store the lower triangles of sub(*A*) and sub (*B*).

n

(global) INTEGER.

The order of the matrices sub(*A*) and sub (*B*) (*n*≥ 0).

a

(local)

COMPLEX for pchegvx

DOUBLE COMPLEX for pzhegvx.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)). On entry, this array contains the local pieces of the *n*-by-*n* Hermitian distributed matrix sub(*A*). If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*A*) contains the upper triangular part of the matrix. If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the matrix.

ia, *ja*

(global) INTEGER.

The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *A*. If *desca*(*ctxt_*) is incorrect, p?hegvx cannot guarantee correct error reporting.

b (local).

COMPLEX for pchegvx

DOUBLE COMPLEX for pzhegvx.

Pointer into the local memory to an array of size (*lld_b*, *LOCc*(*jb*+*n*-1)). On entry, this array contains the local pieces of the *n*-by-*n* Hermitian distributed matrix sub(*B*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*B*) contains the upper triangular part of the matrix.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*B*) contains the lower triangular part of the matrix.

ib, *jb* (global) INTEGER.

The row and column indices in the global matrix *B* indicating the first row and the first column of the submatrix *B*, respectively.

descb (global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *B*. *descb*(*ctxt_*) must be equal to *desca*(*ctxt_*).

vl, *vu* (global)

REAL for pchegvx

DOUBLE PRECISION for pzhegvx.

If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, *iu* (global)

INTEGER.

If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1$, $\min(il, n) \leq iu \leq n$

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol (global)

REAL for pchegvx

DOUBLE PRECISION for pzhegvx.

If *jobz*='V', setting *abstol* to p?lamch(*context*, 'U') yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [*a*,*b*] of width less than or equal to

abstol + *eps**max(|*a*|,|*b*|),

where *eps* is the machine precision. If *abstol* is less than or equal to zero, then *eps**norm(T) will be used in its place, where norm(T) is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form.

Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold 2*p?lamch('S') not zero. If this routine returns with ((mod(*info*,2)≠0).*or*. * (*mod*(*info*/8,2)≠0)), indicating that some eigenvalues or eigenvectors did not converge, try setting *abstol* to 2*p?lamch('S').

NOTE
mod(*x*,*y*) is the integer remainder of *x*/*y*.

orfac (global).

REAL for pchegvx

DOUBLE PRECISION for pzhegvx.

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within *tol*=*orfac**norm(*A*) of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0E-3 is used if *orfac* is negative. *orfac* should be identical on all processes.

iz, *jz* (global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*.*descz*(*ctxt_*) must equal *desca*(*ctxt_*).

work (local)

COMPLEX for pchegvx

DOUBLE COMPLEX for pzhegvx.

Workspace array of size *lwork*

lwork (local).

INTEGER. The size of the array *work*.

If only eigenvalues are requested:

lwork ≥ *n*+ max(NB*(*np*0 + 1), 3)

If eigenvectors are requested:

lwork ≥ *n* + (*np*0+ *mq*0 + NB)*NB

with *nq*0 = numroc(*nn*, NB, 0, 0, NPCOL).

For optimal performance, greater workspace is needed, that is

lwork ≥ max(*lwork*, *n*, *nhetrd_lwopt*, *nhegst_lwopt*)

where *lwork* is as defined above, and

nhetrd_lwork = 2*(*anb*+1)*(4**nps*+2) + (*nps* + 1)**nps*;

nhegst_lwopt = 2**np*0**nb* + *nq*0**nb* + *nb***nb*

nb = *desca*(*mb_*)

*np*0 = numroc(*n*, *nb*, 0, 0, NPROW)

*nq*0 = numroc(*n*, *nb*, 0, 0, NPCOL)

ictxt = *desca*(*ctxt_*)

anb = pjlaenv(*ictxt*, 3, 'p?hettrd', 'L', 0, 0, 0, 0)

sqnpc = *sqrt*(*dble*(NPROW * NPCOL))

nps = max(numroc(*n*, 1, 0, 0, *sqnpc*), 2**anb*)

numroc is a ScaLAPACK tool functions;

pjlaenv is a ScaLAPACK environmental inquiry function MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = –1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.

rwork (local)

REAL for pchegvx

DOUBLE PRECISION for pzhegvx.

Workspace array of size *lrwork*.

lrwork (local) INTEGER. The size of the array *rwork*.

See below for definitions of variables used to define *lrwork*.

If no eigenvectors are requested (*jobz* = 'N'), then *lrwork* ≥ 5**nn*+4**n*

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

lrwork ≥ 4**n* + max(5**nn*, *np*0**mq*0)+iceil(*neig*, NPROW*NPCOL)**nn*

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following value to *lrwork*:

(*clustersize*-1)**n*,

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

{*w*(*k*),..., *w*(*k*+*clustersize*-1)|*w*(*j*+1) ≤ *w*(*j*)+*orfac**2*norm*(*A*)}

Variable definitions:

neig = number of eigenvectors requested;

nb = *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*);

nn = max(*n*, *nb*, 2);

desca(*rsrc_*) = *desca*(*nb_*) = *descz*(*rsrc_*) = *descz*(*csrc_*) = 0 ;

*np*0 = numroc(*nn*, *nb*, 0, 0, NPROW);

*mq*0 = numroc(max(*neig*, *nb*, 2), *nb*, 0, 0, NPCOL);

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*).

When *lrwork* is too small:

If *lwork* is too small to guarantee orthogonality, p?hegvx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -25 is returned. Note that when *range*='V', p?hegvx does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range*='V' and as long as *lwork* is large enough to allow p?hegvx to compute the eigenvalues, p?hegvx will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality & performance:

If *clustersize* > *n*/*sqrt*(NPROW*NPCOL), then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, *clustersize* = *n*-1) p?stein will perform no better than ?stein on 1 processor.

For *clustersize* = *n*/*sqrt*(NPROW*NPCOL) reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For *clustersize*>*n*/*sqrt*(NPROW*NPCOL) execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lrwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.

iwork (local) INTEGER. Workspace array.

liwork (local) INTEGER , size of *iwork*.

liwork ≥ 6**nnp*

Where: *nnp* = max(*n*, NPROW*NPCOL + 1, 4)

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a On exit, if *jobz* = 'V', then if *info* = 0, sub(*A*) contains the distributed matrix *Z* of eigenvectors.

The eigenvectors are normalized as follows:

If *ibtype* = 1 or 2, then Z^H*sub(*B*)**Z* = *i*;

If *ibtype* = 3, then Z^H*inv(sub(*B*))**Z* = *i*.

If *jobz* = 'N', then on exit the upper triangle (if *uplo*='U') or the lower triangle (if *uplo*='L') of sub(*A*), including the diagonal, is destroyed.

b — On exit, if *info* ≤ *n*, the part of sub(*B*) containing the matrix is overwritten by the triangular factor *U* or *L* from the Cholesky factorization sub(*B*) = U^H**U*, or sub(*B*) = *L*L^H.

m — (global) INTEGER. The total number of eigenvalues found, 0 ≤ *m* ≤ *n*.

nz — (global) INTEGER. Total number of eigenvectors computed. 0 < *nz* < *m*. The number of columns of *z* that are filled.

If *jobz* ≠ 'V', *nz* is not referenced.

If *jobz* = 'V', *nz* = *m* unless the user supplies insufficient space and p?hegvx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in *z* (*m*≤*descz*(*n_*)) and sufficient workspace to compute them. (See *lwork* below.) The routine p?hegvx is always able to detect insufficient space without computation unless *range* = 'V'.

w — (global)

REAL for pchegvx

DOUBLE PRECISION for pzhegvx.

Array of size *n*. On normal exit, the first *m* entries contain the selected eigenvalues in ascending order.

z — (local).

COMPLEX for pchegvx

DOUBLE COMPLEX for pzhegvx.

global size (*n*, *n*), local size (*lld_z*, *LOCc*(*jz*+*n*-1)).

If *jobz* = 'V', then on normal exit the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If *jobz* = 'N', then *z* is not referenced.

work — On exit, *work*(1) returns the optimal amount of workspace.

rwork — On exit, *rwork*(1) contains the amount of workspace required for optimal efficiency

If *jobz*='N'*rwork*(1) = optimal amount of workspace required to compute eigenvalues efficiently

If *jobz*='V'*rwork*(1) = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If *range*='V', it is assumed that all eigenvectors may be required when computing optimal workspace.

ifail

(global) INTEGER.

Array of size *n*.

ifail provides additional information when *info*≠0

If (*mod*(*info*/16,2)≠0), then *ifail*(1) indicates the order of the smallest minor which is not positive definite.

If (*mod*(*info*,2)≠0) on exit, then *ifail*(1) contains the indices of the eigenvectors that failed to converge.

If neither of the above error conditions are held, and *jobz* = 'V', then the first *m* elements of *ifail* are set to zero.

iclustr

(global) INTEGER.

Array of size (2*NPROW*NPCOL). This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2*i*–1) to *iclustr*(2*i*), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal.

iclustr() is a zero terminated array. (*iclustr*(2*k*) ≠0.*and*.*clustr*(2*k*+1)=0) if and only if *k* is the number of clusters.

iclustr is not referenced if *jobz* = 'N'.

gap

(global)

REAL for pchegvx

DOUBLE PRECISION for pzhegvx.

Array of size NPROW*NPCOL.

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as (*C**n*)/ *gap*(*i*), where *C* is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* <0: the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = –(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = –*i*.

If *info*> 0:

If (mod(*info*,2)≠0), then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If (mod(*info*,2,2)≠0), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If (mod(*info*/4,2)≠0), then space limit prevented p?sygvx from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If (mod(*info*/8,2)≠0), then p?stebz failed to compute eigenvalues.

If (mod(*info*/16,2)≠0), then *B* was not positive definite. *ifail(1)* indicates the order of the smallest minor which is not positive definite.

ScaLAPACK Auxiliary Routines

ScaLAPACK Auxiliary Routines

Routine Name	Data Types	Description
b?laapp	s,d	Multiplies a matrix with an orthogonal matrix.
b?laexc	s,d	Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation.
b?trexc	s,d	Reorders the Schur factorization of a general matrix.
p?lacgv	c,z	Conjugates a complex vector.
p?max1	c,z	Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS p?amax, but using the absolute value to the real part).
pmpcol	s,d	*Finds the collaborators of a process.*
pmpim2	s,d	Computes the eigenpair range assignments for all processes.
?combamax1	c,z	Finds the element with maximum real part absolute value and its corresponding global index.
p?sum1	sc,dz	Forms the 1-norm of a complex vector similar to Level 1 PBLAS p?asum, but using the true absolute value.
p?dbtrsv	s,d,c,z	Computes an *LU* factorization of a general tridiagonal matrix with no pivoting. The routine is called by p?dbtrs.
p?dttrsv	s,d,c,z	Computes an *LU* factorization of a general band matrix, using partial pivoting with row interchanges. The routine is called by p?dttrs.
p?gebal	s,d	Balances a general real/complex matrix.
p?gebd2	s,d,c,z	Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).
p?gehd2	s,d,c,z	Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm).
p?gelq2	s,d,c,z	Computes an *LQ* factorization of a general rectangular matrix (unblocked algorithm).

Routine Name	Data Types	Description
p?geql2	s,d,c,z	Computes a *QL* factorization of a general rectangular matrix (unblocked algorithm).
p?geqr2	s,d,c,z	Computes a *QR* factorization of a general rectangular matrix (unblocked algorithm).
p?gerq2	s,d,c,z	Computes an *RQ* factorization of a general rectangular matrix (unblocked algorithm).
p?getf2	s,d,c,z	Computes an *LU* factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).
p?labrd	s,d,c,z	Reduces the first *nb* rows and columns of a general rectangular matrix A to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.
p?lacon	s,d,c,z	Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.
p?laconsb	s,d	Looks for two consecutive small subdiagonal elements.
p?lacp2	s,d,c,z	Copies all or part of a distributed matrix to another distributed matrix.
p?lacp3	s,d	Copies from a global parallel array into a local replicated array or vice versa.
p?lacpy	s,d,c,z	Copies all or part of one two-dimensional array to another.
p?laevswp	s,d,c,z	Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.
p?lahrd	s,d,c,z	Reduces the first *nb* columns of a general rectangular matrix A so that elements below the k^{th} subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.
p?laiect	s,d,c,z	Exploits IEEE arithmetic to accelerate the computations of eigenvalues. (C interface function).
p?lamve	s, d	Copies all or part of one two-dimensional distributed array to another.
p?lange	s,d,c,z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.
p?lanhs	s,d,c,z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.
p?lansy, p?lanhe	s,d,c,z/c,z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a real symmetric or complex Hermitian matrix.
p?lantr	s,d,c,z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.

Routine Name	Data Types	Description
p?lapiv	s,d,c,z	Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.
p?laqge	s,d,c,z	Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ.
p?laqr0	s,d	Computes the eigenvalues of a Hessenberg matrix and optionally returns the matrices from the Schur decomposition.
p?laqr1	s,d	Sets a scalar multiple of the first column of the product of a 2-by-2 or 3-by-3 matrix and specified shifts.
p?laqr2	s,d	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
p?laqr3	s,d	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
p?laqr4	s,d	Computes the eigenvalues of a Hessenberg matrix, and optionally computes the matrices from the Schur decomposition.
p?laqr5	s,d	Performs a single small-bulge multi-shift QR sweep.
p?laqsy	s,d,c,z	Scales a symmetric/Hermitian matrix, using scaling factors computed by p?poequ.
p?lared1d	s,d	Redistributes an array assuming that the input array *bycol* is distributed across rows and that all process columns contain the same copy of *bycol*.
p?lared2d	s,d	Redistributes an array assuming that the input array *byrow* is distributed across columns and that all process rows contain the same copy of *byrow* .
p?larf	s,d,c,z	Applies an elementary reflector to a general rectangular matrix.
p?larfb	s,d,c,z	Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.
p?larfc	c,z	Applies the conjugate transpose of an elementary reflector to a general matrix.
p?larfg	s,d,c,z	Generates an elementary reflector (Householder matrix).
p?larft	s,d,c,z	Forms the triangular vector *T* of a block reflector $H=I-VTV^H$
p?larz	s,d,c,z	Applies an elementary reflector as returned by p?tzrzf to a general matrix.
p?larzb	s,d,c,z	Applies a block reflector or its transpose/conjugate-transpose as returned by p?tzrzf to a general matrix.
p?larzc	c,z	Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by p?tzrzf to a general matrix.

Routine Name	Data Types	Description
p?larzt	s,d,c,z	Forms the triangular factor *T* of a block reflector $H=I-VTV^H$ as returned by p?tzrzf.
p?lascl	s,d,c,z	Multiplies a general rectangular matrix by a real scalar defined as C_{to}/C_{from}.
p?laset	s,d,c,z	Initializes the off-diagonal elements of a matrix to α and the diagonal elements to β.
p?lasmsub	s,d	Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.
p?lassq	s,d,c,z	Updates a sum of squares represented in scaled form.
p?laswp	s,d,c,z	Performs a series of row interchanges on a general rectangular matrix.
p?latra	s,d,c,z	Computes the trace of a general square distributed matrix.
p?latrd	s,d,c,z	Reduces the first *nb* rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.
p?latrz	s,d,c,z	Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.
p?lauu2	s,d,c,z	Computes the product UU^H or L^HL, where *U* and *L* are upper or lower triangular matrices (local unblocked algorithm).
p?lauum	s,d,c,z	Computes the product UU^H or L^HL, where *U* and *L* are upper or lower triangular matrices.
p?lawil	s,d	Forms the Wilkinson transform.
p?org2l/p?ung2l	s,d,c,z	Generates all or part of the orthogonal/unitary matrix *Q* from a *QL* factorization determined by p?geqlf (unblocked algorithm).
p?org2r/p?ung2r	s,d,c,z	Generates all or part of the orthogonal/unitary matrix *Q* from a *QR* factorization determined by p?geqrf (unblocked algorithm).
p?orgl2/p?ungl2	s,d,c,z	Generates all or part of the orthogonal/unitary matrix *Q* from an *LQ* factorization determined by p?gelqf (unblocked algorithm).
p?orgr2/p?ungr2	s,d,c,z	Generates all or part of the orthogonal/unitary matrix *Q* from an *RQ* factorization determined by p?gerqf (unblocked algorithm).
p?orm2l/p?unm2l	s,d,c,z	Multiplies a general matrix by the orthogonal/unitary matrix from a *QL* factorization determined by p?geqlf (unblocked algorithm).
p?orm2r/p?unm2r	s,d,c,z	Multiplies a general matrix by the orthogonal/unitary matrix from a *QR* factorization determined by p?geqrf (unblocked algorithm).
p?orml2/p?unml2	s,d,c,z	Multiplies a general matrix by the orthogonal/unitary matrix from an *LQ* factorization determined by p?gelqf (unblocked algorithm).
p?ormr2/p?unmr2	s,d,c,z	Multiplies a general matrix by the orthogonal/unitary matrix from an *RQ* factorization determined by p?gerqf (unblocked algorithm).

Routine Name	Data Types	Description
p?pbtrsv	s,d,c,z	Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a banded matrix computed by p?pbtrf.
p?pttrsv	s,d,c,z	Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a tridiagonal matrix computed by p?pttrf.
p?potf2	s,d,c,z	Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).
p?rot	s,d	Applies a planar rotation to two distributed vectors.
p?rscl	s,d,cs,zd	Multiplies a vector by the reciprocal of a real scalar.
p?sygs2/p?hegs2	s,d,c,z	Reduces a symmetric/Hermitian positive-definite generalized eigenproblem to standard form, using the factorization results obtained from p?potrf (local unblocked algorithm).
p?sytd2/p?hetd2	s,d,c,z	Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).
p?trord	s,d	Reorders the Schur factorization of a general matrix.
p?trsen	s,d	Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers and invariant subspace for the selected cluster of eigenvalues.
p?trti2	s,d,c,z	Computes the inverse of a triangular matrix (local unblocked algorithm).
?lamsh	s,d	Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.
?laqr6	s,d	Performs a single small-bulge multi-shift QR sweep collecting the transformations.
?lar1va	s,d	*Computes scaled eigenvector corresponding to given eigenvalue.*
?laref	s,d	Applies Householder reflectors to matrices on either their rows or columns.
?larrb2	s,d	Provides limited bisection to locate eigenvalues for more accuracy.
?larrd2	s,d	Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.
?larre2	s,d	Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.
?larre2a	s,d	*Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.*
?larrf2	s,d	Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.
?larrv2	s,d	Computes the eigenvectors of the tridiagonal matrix $T = L*D*L^T$ given L, D and the eigenvalues of $L*D*L^T$.

Routine Name	Data Types	Description
?lasorte	s,d	Sorts eigenpairs by real and complex data types.
?lasrt2	s,d	Sorts numbers in increasing or decreasing order.
?stegr2	s,d	Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.
?stegr2a	s,d	Computes selected eigenvalues and initial representations needed for eigenvector computations.
?stegr2b	s,d	From eigenvalues and initial representations computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors.
?stein2	s,d	Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.
?dbtf2	s,d,c,z	Computes an *LU* factorization of a general band matrix with no pivoting (local unblocked algorithm).
?dbtrf	s,d,c,z	Computes an *LU* factorization of a general band matrix with no pivoting (local blocked algorithm).
?dttrf	s,d,c,z	Computes an *LU* factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).
?dttrsv	s,d,c,z	Solves a general tridiagonal system of linear equations using the *LU* factorization computed by ?dttrf.
?pttrsv	s,d,c,z	Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the LDL^H factorization computed by ?pttrf.
?steqr2	s,d	Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit *QL* or *QR* method.
?trmvt	s,d,c,z	Performs matrix-vector operations.
pilaenv	NA	Returns the positive integer value of the logical blocking size.
pilaenvx	NA	Called from the ScaLAPACK routines to choose problem-dependent parameters for the local environment.
pjlaenv	NA	Called from the ScaLAPACK symmetric and Hermitian tailored eigen-routines to choose problem-dependent parameters for the local environment.

b?laapp

Multiplies a matrix with an orthogonal matrix.

Syntax

```
call bslaapp( iside, m, n, nb, a, lda, nitraf, itraf, dtraf, work )
```

```
call bdlaapp( iside, m, n, nb, a, lda, nitraf, itraf, dtraf, work )
```

Description

b?laapp computes

$B = Q^T A$ or $B = AQ$

where A is an m-by-n matrix and Q is an orthogonal matrix represented by the parameters in the arrays *itraf* and *dtraf* as described in b?trexc.

This is an auxiliary routine called by p?trord.

Input Parameters

iside — INTEGER

Specifies whether Q multiplies A from the left or right as follows:

= 0: compute $B = Q^T A$;

= 1: compute $B = AQ$.

m — INTEGER

The number of rows of A.

n — INTEGER

The number of columns of A.

nb — INTEGER

If *iside* = 0, the Q is applied block column-wise to the rows of A and *nb* specifies the maximal width of the block columns.

If *iside* = 1, this variable is not referenced.

a — REAL for bslaapp

DOUBLE PRECISION for bdlaapp

Array of size (*lda*,*n*).

On entry, the matrix A.

lda — INTEGER

The leading dimension of the array *a*. *lda* ≥ max(1,*n*).

nitraf — INTEGER

Length of the array *itraf*. *nitraf* ≥ 0.

itraf — INTEGER array, length *nitraf*

List of parameters for representing the transformation matrix Q, see b?trexc.

work — (workspace) REAL array of size *n*.

OUTPUT Parameters

a — *a* is overwritten by B.

dtraf — REAL for bslaapp

DOUBLE PRECISION for bdlaapp

Array, length *k*.

If *iside*=0, *k* = 3*(*n*/*nb*).

If *iside*=1, *k* = 3**nitraf*.

List of parameters for representing the transformation matrix *Q*, see b?trexc

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

b?laexc

Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation.

Syntax

```
call bslaexc( n, t, ldt, j1, n1, n2, itraf, dtraf, work, info )
call bdlaexc( n, t, ldt, j1, n1, n2, itraf, dtraf, work, info )
```

Description

b?laexc swaps adjacent diagonal blocks *T11* and *T22* of order 1 or 2 in an upper quasi-triangular matrix *T* by an orthogonal similarity transformation.

In contrast to the LAPACK routine ?laexc, the orthogonal transformation matrix *Q* is not explicitly constructed but represented by parameters contained in the arrays *itraf* and *dtraf*. See the description of b?trexc for more details.

T must be in Schur canonical form, that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Input Parameters

n

INTEGER

The order of the matrix *T*. *n*≥ 0.

t

REAL for bslaexc

DOUBLE PRECISION for bdlaexc

Array of size (*ldt*,*n*).

The upper quasi-triangular matrix *T*, in Schur canonical form.

ldt

INTEGER

The leading dimension of the array *t*. *ldt*≥ max(1,*n*).

j1

INTEGER

The index of the first row of the first block *T11*.

n1

INTEGER

The order of the first block *T11*. *n1* = 0, 1 or 2.

n2 INTEGER

The order of the second block *T22*. *n2* = 0, 1 or 2.

work REAL for bslaexc

DOUBLE PRECISION for bdlaexc

(Workspace) array of size *n*.

OUTPUT Parameters

t The updated matrix *T*, in Schur canonical form.

itraf INTEGER array, length *k*, where

k = 1, if *n1*+*n2* = 2;

k = 2, if *n1*+*n2* = 3;

k = 4, if *n1*+*n2* = 4.

List of parameters for representing the transformation matrix *Q*, see b?trexc.

dtraf REAL for bslaexc

DOUBLE PRECISION for bdlaexc

Array, length *k*, where

k = 2, if *n1*+*n2* = 2;

k = 5, if *n1*+*n2* = 3;

k = 10, if *n1*+*n2* = 4.

List of parameters for representing the transformation matrix *Q*, see b?trexc.

info INTEGER

= 0: successful exit

= 1: the transformed matrix *T* would be too far from Schur form; the blocks are not swapped and *T* and *Q* are unchanged.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

b?trexc

Reorders the Schur factorization of a general matrix.

Syntax

```
call bstrexc( n, t, ldt, ifst, ilst, nitraf, itraf, ndtraf, dtraf, work, info )
call bdtrexc( n, t, ldt, ifst, ilst, nitraf, itraf, ndtraf, dtraf, work, info )
```

Description

b?trexc reorders the real Schur factorization of a real matrix $A = Q * T * Q^T$, so that the diagonal block of *T* with row index *ifst* is moved to row *ilst*.

The real Schur form *T* is reordered by an orthogonal similarity transformation $Z^T * T * Z$. In contrast to the LAPACK routine ?trexc, the orthogonal matrix *Z* is not explicitly constructed but represented by parameters contained in the arrays *itraf* and *dtraf*. See Application Notes for further details.

T must be in Schur canonical form (as returned by ?hseqr), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Input Parameters

n

INTEGER

The order of the matrix *T*. $n \geq 0$.

t

REAL for bstrexc

DOUBLE PRECISION for bdtrexc

Array of size (*ldt*,*n*).

The upper quasi-triangular matrix *T*, in Schur canonical form.

ldt

INTEGER

The leading dimension of the array *t*. $ldt \geq \max(1,n)$.

ifst, *ilst*

INTEGER

Specify the reordering of the diagonal blocks of *T*. The block with row index *ifst* is moved to row *ilst*, by a sequence of transpositions between adjacent blocks.

nitraf

INTEGER

Length of the array *itraf*.

As a minimum requirement, $nitraf \geq \max(1,|ilst-ifst|)$.

If there are 2-by-2 blocks in *t* then *nitraf* must be larger; a safe choice is $nitraf \geq \max(1,2*|ilst-ifst|)$.

ndtraf

INTEGER

Length of the array *dtraf*.

As a minimum requirement, $ndtraf \geq \max(1,2*|ilst-ifst|)$.

If there are 2-by-2 blocks in *t* then *ndtraf* must be larger; a safe choice is $ndtraf \geq \max(1,5*|ilst-ifst|)$.

work

REAL for bstrexc

DOUBLE PRECISION for bdtrexc

(Workspace) array of size *n*.

OUTPUT Parameters

t

On exit, the reordered upper quasi-triangular matrix, in Schur canonical form.

ifst, *ilst*

If *ifst* pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; *ilst* always points to the first row of the block in its final position (which may differ from its input value by +1 or -1).

	1 ≤*ifst*≤*n*; 1 ≤*ilst*≤*n*.
nitraf	Actual length of the array *itraf*.
itraf	INTEGER array, length *nitraf* List of parameters for representing the transformation matrix *Z*. See Application Notes for further details.
ndtraf	Actual length of the array *dtraf*.
dtraf	REAL for bstrexc DOUBLE PRECISION for bdtrexc Array, length *ndtraf* List of parameters for representing the transformation matrix *Z*. See Application Notes for further details.
info	INTEGER = 0: successful exit < 0: if *info* = -*i*, the *i*-th argument had an illegal value = 1: two adjacent blocks were too close to swap (the problem is very ill-conditioned); *t* may have been partially reordered, and *ilst* points to the first row of the current position of the block being moved. = 2: the 2 by 2 block to be reordered split into two 1 by 1 blocks and the second block failed to swap with an adjacent block. *ilst* points to the first row of the current position of the whole block being moved.

Application Notes

The orthogonal transformation matrix *Z* is a product of *nitraf* elementary orthogonal transformations. The parameters defining these transformations are stored in the arrays *itraf* and *dtraf* as follows:

Consider the *i*-th transformation acting on rows/columns *pos*, *pos*+1, ... If this transformation is

- a Givens rotation with cosine *c* and sine *s* then

  itraf(*i*)= *pos*, *dtraf*(*i*) = *c*, *dtraf*(*i*+1) = *s*;
- a Householder reflector *H* = *I* - *t* * *v* * *v*' with *v* = [1; *v2*; *v3*] then

  itraf(*i*) = *n* + *pos*, *dtraf*(*i*) = *t*, *dtraf*(*i*+1) = *v2*, *dtraf*(*i*+2) = v3;
- a Householder reflector H = I - *t** *v* * *v*' with *v* = [*v1*; *v2*; 1] then

  itraf(*i*) = 2**n* + *pos*, *dtraf*(*i*) = *v1*, *dtraf*(*i*+1) = *v2*, *dtraf*(*i*+2) = *t*;

Note that the parameters in *dtraf* are stored consecutively.

p?lacgv

Conjugates a complex vector.

Syntax

```
call pclacgv(n, x, ix, jx, descx, incx)
call pzlacgv(n, x, ix, jx, descx, incx)
```

Description

The p?lacgvroutine conjugates a complex vector sub(*X*) of length *n*, where sub(*X*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*:*ix*+*n*-1, *jx*) if *incx* = 1.

Input Parameters

n — (global) INTEGER. The length of the distributed vector sub(*X*).

x — (local).

COMPLEX for pclacgv

COMPLEX*16 for pzlacgv.

Pointer into the local memory to an array of size (*lld_x*,*). On entry the vector to be conjugated *x*(i) = *X*(*ix*+(*jx*-1)*m_x+(*i*-1)**incx*), 1 ≤ *i* ≤ *n*.

ix — (global) INTEGER. The row index in the global matrix *X* indicating the first row of sub(*X*).

jx — (global) INTEGER. The column index in the global matrix *X* indicating the first column of sub(*X*).

descx — (global and local) INTEGER. Array of size *dlen_*=9. The array descriptor for the distributed matrix *X*.

incx — (global) INTEGER. The global increment for the elements of *X*. Only two values of *incx* are supported in this version, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

x — (local).

On exit, the local pieces of conjugated distributed vector sub(*X*).

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?max1

Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS p?amax, but using the absolute value to the real part).

Syntax

```
call pcmax1(n, amax, indx, x, ix, jx, descx, incx)
call pzmax1(n, amax, indx, x, ix, jx, descx, incx)
```

Description

The p?max1routine computes the global index of the maximum element in absolute value of a distributed vector sub(*X*). The global index is returned in *indx* and the value is returned in *amax*, where sub(*X*) denotes *X*(*ix*:*ix*+*n*-1, *jx*) if *incx* = 1, *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*.

Input Parameters

n	(global) pointer to INTEGER. The number of components of the distributed vector sub(*X*). $n \geq 0$.
x	(local) COMPLEX for pcmax1. COMPLEX*16 for pzmax1 Pointer into the local memory to an array of size (*lld_x*, *LOCc*(*jx*+*n*-1)). On entry this array contains the local pieces of the distributed vector sub(*X*).
ix	(global) INTEGER. The row index in the global matrix *X* indicating the first row of sub(*X*).
jx	(global) INTEGER. The column index in the global matrix *X* indicating the first column of sub(*X*).
descx	(global and local) INTEGER. Array of size *dlen_*. The array descriptor for the distributed matrix *X*.
incx	(global)INTEGER.The global increment for the elements of *X*. Only two values of *incx* are supported in this version, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

amax	(global output) pointer to REAL.The absolute value of the largest entry of the distributed vector sub(*X*) only in the scope of sub(*X*).
indx	(global output) pointer to INTEGER.The global index of the element of the distributed vector sub(*X*) whose real part has maximum absolute value.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

pilaver

Returns the ScaLAPACK version.

Syntax

```
call pilaver (vers_major, vers_minor, vers_patch )
```

Description

This subroutine returns the ScaLAPACK version.

Output Parameters

vers_major	INTEGER. Return the ScaLAPACK major version.
vers_minor	INTEGER. Return the ScaLAPACK minor version from the major version.
vers_patch	INTEGER.

Return the ScaLAPACK patch version from the minor version.

pmpcol

Finds the collaborators of a process.

Syntax

```
call pmpcol( myproc, nprocs, iil, needil, neediu, pmyils, pmyius, colbrt, frstcl,
lastcl )
```

Description

Using the output from pmpim2 and given the information on eigenvalue clusters, pmpcol finds the collaborators of *myproc*.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.
Notice revision #20201201

Input Parameters

myproc INTEGER

The processor number, 0 ≤*myproc* < *nprocs*.

nprocs INTEGER

The total number of processors available.

iil INTEGER

The index of the leftmost eigenvalue in the eigenvalue cluster.

needil INTEGER

The leftmost position in the eigenvalue cluster needed by *myproc*.

neediu INTEGER

The rightmost position in the eigenvalue cluster needed by *myproc*.

pmyils INTEGER array

For each processor *p*, 0 < *p*≤*nprocs*, *pmyils*(*p*) is the index of the first eigenvalue in the eigenvalue cluster to be computed.

pmyils(*p*) equals zero if *p* stays idle.

pmyius INTEGER array

For each processor *p*, *pmyius*(*p*) is the index of the last eigenvalue in the eigenvalue cluster to be computed.

pmyius(*p*) equals zero if *p* stays idle.

OUTPUT Parameters

colbrt LOGICAL

Equals .TRUE. if *myproc* collaborates.

frstcl, *lastcl*

INTEGER

First and last collaborator of *myproc* .

myproc collaborates with:

frstcl, ..., *myproc*-1, *myproc*+1, ...,*lastcl*

If *myproc* = *frstcl*, there are no collaborators on the left. If *myproc* = *lastcl*, there are no collaborators on the right.

If *frstcl* = 0 and *lastcl* = *nprocs*-1, then *myproc* collaborates with everybody

pmpim2

Computes the eigenpair range assignments for all processes.

Syntax

```
call pmpim2( il, iu, nprocs, pmyils, pmyius )
```

Description

pmpim2 is the scheduling subroutine. It computes for all processors the eigenpair range assignments.

Input Parameters

il, *iu*

INTEGER

The range of eigenpairs to be computed.

nprocs

INTEGER

The total number of processors available.

Output Parameters

pmyils

INTEGER array

For each processor *p*, *pmyils*(*p*) is the index of the first eigenvalue in a cluster to be computed.

pmyils(*p*) equals zero if *p* stays idle.

pmyius

INTEGER array

For each processor *p*, *pmyius*(*p*) is the index of the last eigenvalue in a cluster to be computed.

pmyius(*p*) equals zero if *p* stays idle.

?combamax1

Finds the element with maximum real part absolute value and its corresponding global index.

Syntax

```
call ccombamax1(v1, v2)
call zcombamax1(v1, v2)
```

Description

The ?combamax1routine finds the element having maximum real part absolute value as well as its corresponding global index.

Input Parameters

v1 (local)

COMPLEX for ccombamax1

COMPLEX*16 for zcombamax1

Array of size 2. The first maximum absolute value element and its global index. *v1*(1)=amax, *v1*(2)=indx.

v2 (local)

COMPLEX for ccombamax1

COMPLEX*16 for zcombamax1

Array of size 2. The second maximum absolute value element and its global index. *v2*(1)=amax, *v2*(2)=indx.

Output Parameters

v1 (local).

The first maximum absolute value element and its global index. *v1*(1)=amax, *v1*(2)=indx.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?sum1

Forms the 1-norm of a complex vector similar to Level 1 PBLAS p?asum*, but using the true absolute value.*

Syntax

```
call pscsum1(n, asum, x, ix, jx, descx, incx)
call pdzsum1(n, asum, x, ix, jx, descx, incx)
```

Description

The p?sum1routine returns the sum of absolute values of a complex distributed vector sub(*x*) in *asum*, where sub(*x*) denotes *X*(*ix*:*ix*+*n*-1, *jx*:*jx*), if *incx* = 1, *X*(*ix*:*ix*, *jx*:*jx*+*n*-1), if *incx* = *m_x*.

Based on p?asum from the Level 1 PBLAS. The change is to use the 'genuine' absolute value.

Input Parameters

n	(global) pointer to INTEGER. The number of components of the distributed vector sub(*x*). $n \geq 0$.
x	(local) COMPLEX for pscsum1 COMPLEX*16 for pdzsum1. Pointer into the local memory to an array of size (*lld_x*, *LOCc*(*jx*+*n*-1)). This array contains the local pieces of the distributed vector sub(*X*).
ix	(global) INTEGER.The row index in the global matrix *X* indicating the first row of sub(*X*).
jx	(global) INTEGER. The column index in the global matrix *X* indicating the first column of sub(*X*)
descx	(local) INTEGER. Array of size *dlen_*=9. The array descriptor for the distributed matrix *X*.
incx	(global) INTEGER.The global increment for the elements of *X*. Only two values of *incx* are supported in this version, namely 1 and *m_x*.

Output Parameters

asum	(local) Pointer to REAL. The sum of absolute values of the distributed vector sub(*X*) only in its scope.

p?dbtrsv

Computes an LU factorization of a general triangular matrix with no pivoting. The routine is called by p?dbtrs.

Syntax

```
call psdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pddbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pcdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pzdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork, info)
```

Description

The p?dbtrsvroutine solves a banded triangular system of linear equations

A(1 :*n*, *ja*:*ja*+*n*-1) * *X* = *B*(*ib*:*ib*+*n*-1, 1 :*nrhs*) or

A(1 :*n*, *ja*:*ja*+*n*-1)^T * *X* = *B*(*ib*:*ib*+*n*-1, 1 :*nrhs*) (for real flavors); *A*(1 :*n*, *ja*:*ja*+*n*-1)^H* *X* = *B*(*ib*:*ib*+*n*-1, 1 :*nrhs*) (for complex flavors),

where *A*(1 :*n*, *ja*:*ja*+*n*-1) is a banded triangular matrix factor produced by the Gaussian elimination code of p?dbtrf and is stored in *A*(1 :*n*, *ja*:*ja*+*n*-1) and *af*. The matrix stored in *A*(1 :*n*, *ja*:*ja*+*n*-1) is either upper or lower triangular according to *uplo*, and the choice of solving *A*(1 :*n*, *ja*:*ja*+*n*-1) or *A*(1 :*n*, *ja*:*ja*+*n*-1)^T is dictated by the user by the parameter *trans*.

The routine p?dbtrf must be called first.

Input Parameters

uplo

(global) CHARACTER.

If *uplo*='U', the upper triangle of *A*(1:*n*, *ja*:*ja*+*n*-1) is stored,

if *uplo* = 'L', the lower triangle of *A*(1:*n*, *ja*:*ja*+*n*-1) is stored.

trans

(global) CHARACTER.

If *trans* = 'N', solve with *A*(1:*n*, *ja*:*ja*+*n*-1),

if *trans* = 'C', solve with conjugate transpose *A*(1:*n*, *ja*:*ja*+*n*-1).

n

(global) INTEGER. The order of the distributed submatrix *A*;(*n*≥ 0).

bwl

(global) INTEGER. Number of subdiagonals. 0 ≤ *bwl* ≤ *n*-1.

bwu

(global) INTEGER. Number of subdiagonals. 0 ≤ *bwu* ≤ *n*-1.

nrhs

(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix *B* (*nrhs*≥ 0).

a

(local).

REAL for psdbtrsv

DOUBLE PRECISION for pddbtrsv

COMPLEX for pcdbtrsv

COMPLEX*16 for pzdbtrsv.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)), where *lld_a*≥(*bwl*+*bwu*+1). On entry, this array contains the local pieces of the *n*-by-*n* unsymmetric banded distributed Cholesky factor *L* or L^T, represented in global *A* as *A*(1 :*n*, *ja*:*ja*+*n*-1). This local portion is stored in the packed banded format used in LAPACK. See the *Application Notes* below and the ScaLAPACK manual for more detail on the format of distributed matrices.

ja

(global) INTEGER. The index in the global matrix *A* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca

(global and local) INTEGER array of size *dlen_*.

if 1*d* type (*dtype_a* = 501 or 502), *dlen*≥ 7;

if 2*d* type (*dtype_a* = 1), *dlen*≥ 9. The array descriptor for the distributed matrix *A*. Contains information of mapping of *A* to memory.

b

(local)

REAL for psdbtrsv

DOUBLE PRECISION for pddbtrsv

COMPLEX for pcdbtrsv

COMPLEX*16 for pzdbtrsv.

Pointer into the local memory to an array of local lead dimension *lld_b*≥*nb*. On entry, this array contains the local pieces of the right-hand sides *B*(*ib*:*ib*+*n*-1, 1:*nrhs*).

ib

(global) INTEGER. The row index in the global matrix *B* that points to the first row of the matrix to be operated on (which may be either all of *B* or a submatrix of *B*).

descb

(global and local) INTEGER array of size *dlen_*.

if 1*d* type (*dtype_b* =502), *dlen*≥7;

if 2*d* type (*dtype_b* =1), *dlen*≥9. The array descriptor for the distributed matrix *B*. Contains information of mapping *B* to memory.

laf

(local)

INTEGER. Size of user-input auxiliary fill-in space *af*.

laf≥*nb**(*bwl*+*bwu*)+6*max(*bwl*, *bwu*)*max(*bwl*, *bwu*). If *laf* is not large enough, an error code is returned and the minimum acceptable size will be returned in *af*(1).

work

(local).

REAL for psdbtrsv

DOUBLE PRECISION for pddbtrsv

COMPLEX for pcdbtrsv

COMPLEX*16 for pzdbtrsv.

Temporary workspace. This space may be overwritten in between calls to routines.

work must be the size given in *lwork*.

lwork

(local or global) INTEGER.

Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

lwork≥ max(*bwl*, *bwu*)**nrhs*.

Output Parameters

a

(local).

This local portion is stored in the packed banded format used in LAPACK. Please see the ScaLAPACK manual for more detail on the format of distributed matrices.

b — On exit, this contains the local piece of the solutions distributed matrix *X*.

af — (local).

`REAL` for `psdbtrsv`

`DOUBLE PRECISION` for `pddbtrsv`

`COMPLEX` for `pcdbtrsv`

`COMPLEX*16` for `pzdbtrsv`.

auxiliary fill-in space. The fill-in space is created in a call to the factorization routine `p?dbtrf` and is stored in *af*. If a linear system is to be solved using `p?dbtrf` after the factorization routine, *af* must not be altered after the factorization.

work — On exit, *work*`(1)` contains the minimal *lwork*.

info — (local).

`INTEGER`. If *info* = 0, the execution is successful.

< 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info*`= - (`*i*`*100+`*j*`)`, if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?dttrsv

Computes an LU factorization of a general band matrix, using partial pivoting with row interchanges. The routine is called by `p?dttrs`.

Syntax

```
call psdttrsv(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pddttrsv(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pcdttrsv(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pzdttrsv(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf, work, lwork, info)
```

Description

The `p?dttrsv`routine solves a tridiagonal triangular system of linear equations

A`(1 :`*n*`, `*ja*`:`*ja*`+`*n*`-1)*`*X* `= `*B*`(`*ib*`:`*ib*`+`*n*`-1, 1 :`*nrhs*`)` or

A`(1 :`*n*`, `*ja*`:`*ja*`+`*n*`-1)`^{T} `* `*X* `= `*B*`(`*ib*`:`*ib*`+`*n*`-1, 1 :`*nrhs*`)` for real flavors; *A*`(1 :`*n*`, `*ja*`:`*ja*`+`*n*`-1)`^{H}`* `*X* `= `*B*`(`*ib*`:`*ib*`+`*n*`-1, 1 :`*nrhs*`)` for complex flavors,

where A(1 :n, ja:ja+n-1) is a tridiagonal matrix factor produced by the Gaussian elimination code of p?dttrf and is stored in A(1 :n, ja:ja+n-1) and *af*.

The matrix stored in A(1 :n, ja:ja+n-1) is either upper or lower triangular according to *uplo*, and the choice of solving A(1 :n, ja:ja+n-1) or $A(1:n, ja:ja+n-1)^T$ is dictated by the user by the parameter *trans*.

The routine p?dttrf must be called first.

Input Parameters

uplo

(global) CHARACTER.

If *uplo*='U', the upper triangle of A(1:n, ja:ja+n-1) is stored,

if *uplo* = 'L', the lower triangle of *A*(1:*n*, ja:ja+n-1) is stored.

trans

(global) CHARACTER.

If *trans* = 'N', solve with A(1:n, ja:ja+n-1),

if *trans* = 'C', solve with conjugate transpose A(1:n, ja:ja+n-1).

n

(global) INTEGER. The order of the distributed submatrix *A*; (*n*≥ 0).

nrhs

(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix B(*ib*:*ib*+*n*-1, 1:*nrhs*). (*nrhs*≥ 0).

dl

(local).

REAL for psdttrsv

DOUBLE PRECISION for pddttrsv

COMPLEX for pcdttrsv

COMPLEX*16 for pzdttrsv.

Pointer to local part of global vector storing the lower diagonal of the matrix.

Globally, *dl*(1) is not referenced, and *dl* must be aligned with *d*.

Must be of size ≥*nb_a*.

d

(local).

REAL for psdttrsv

DOUBLE PRECISION for pddttrsv

COMPLEX for pcdttrsv

COMPLEX*16 for pzdttrsv.

Pointer to local part of global vector storing the main diagonal of the matrix.

du

(local).

REAL for psdttrsv

DOUBLE PRECISION for pddttrsv

COMPLEX for pcdttrsv

COMPLEX*16 for pzdttrsv.

Pointer to local part of global vector storing the upper diagonal of the matrix.

Globally, *du*(*n*) is not referenced, and *du* must be aligned with *d*.

ja

(global) INTEGER. The index in the global matrix *A* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca

(global and local) INTEGER array of size *dlen_*.

if 1*d* type (*dtype_a* = 501 or 502), *dlen*≥ 7;

if 2*d* type (*dtype_a* = 1), *dlen*≥ 9.

The array descriptor for the distributed matrix *A*. Contains information of mapping of *A* to memory.

b

(local)

REAL for psdttrsv

DOUBLE PRECISION for pddttrsv

COMPLEX for pcdttrsv

COMPLEX*16 for pzdttrsv.

Pointer into the local memory to an array of local lead dimension *lld_b*≥*nb*. On entry, this array contains the local pieces of the right-hand sides *B*(*ib*:*ib*+*n*-1, 1 :*nrhs*).

ib

(global) INTEGER. The row index in the global matrix *B* that points to the first row of the matrix to be operated on (which may be either all of *B* or a submatrix of *B*).

descb

(global and local) INTEGER array of size *dlen_*.

if 1*d* type (*dtype_b* = 502), *dlen*≥7;

if 2*d* type (*dtype_b* = 1), *dlen*≥ 9.

The array descriptor for the distributed matrix *B*. Contains information of mapping *B* to memory.

laf

(local).

INTEGER.

Size of user-input auxiliary fill-in space *af*.

laf≥ 2*(*nb*+2). If *laf* is not large enough, an error code is returned and the minimum acceptable size will be returned in *af*(1).

work

(local).

REAL for psdttrsv

DOUBLE PRECISION for pddttrsv

COMPLEX for pcdttrsv

COMPLEX*16 for pzdttrsv.

Temporary workspace. This space may be overwritten in between calls to routines.

work must be the size given in *lwork*.

lwork

(local or global) INTEGER.

Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

lwork≥ 10*npcol+4*nrhs.

Output Parameters

dl

(local).

On exit, this array contains information containing the factors of the matrix.

d

On exit, this array contains information containing the factors of the matrix. Must be of size ≥*nb_a*.

b

On exit, this contains the local piece of the solutions distributed matrix X.

af

(local).

REAL for psdttrsv

DOUBLE PRECISION for pddttrsv

COMPLEX for pcdttrsv

COMPLEX*16 for pzdttrsv.

Auxiliary fill-in space. The fill-in space is created in a call to the factorization routine p?dttrf and is stored in *af*. If a linear system is to be solved using p?dttrs after the factorization routine, *af* must not be altered after the factorization.

work

On exit, work(1) contains the minimal *lwork*.

info

(local). INTEGER.

If *info*=0, the execution is successful.

if *info*< 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = - (*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?gebal

Balances a general real/complex matrix.

Syntax

```
call psgebal( job, n, a, desca, ilo, ihi, scale, info )
call pdgebal( job, n, a, desca, ilo, ihi, scale, info )
call pcgebal( job, n, a, desca, ilo, ihi, scale, info )call pzgebal( job, n, a, desca, ilo, ihi, scale, info )
```

Description

p?gebal balances a general real/complex matrix *A*. This involves, first, permuting *A* by a similarity transformation to isolate eigenvalues in the first 1 to *ilo*-1 and last *ihi*+1 to *n* elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns *ilo* to *ihi* to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

Input Parameters

job

(global) CHARACTER*1

Specifies the operations to be performed on *a*:

= 'N': none: simply set *ilo* = 1, *ihi* = *n*, *scale*(*i*) = 1.0 for *i* = 1,...,*n*;

= 'P': permute only;

= 'S': scale only;

= 'B': both permute and scale.

n

(global) INTEGER

The order of the matrix *A* ($n \geq 0$).

a

REAL for psgebal

DOUBLE PRECISION for pdgebal

COMPLEX for pcgebal

COMPLEX DOUBLE for pzgebal

(local) Pointer into the local memory to an array of size (*lld_a*, $LOC_c(n)$)

This array contains the local pieces of global input matrix *A*.

desca

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *A*.

OUTPUT Parameters

a

On exit, *a* is overwritten by the balanced matrix.

If *job* = 'N', *a* is not referenced.

See Notes for further details.

ilo, *ihi*

(global) INTEGER

ilo and *ihi* are set to integers such that on exit matrix elements *A*(*i*,*j*) are zero if *i* > *j* and *j* = 1,...,*ilo*-1 or *i* = *ihi*+1,...,*n*.

If *job* = 'N' or 'S', *ilo* = 1 and *ihi* = *n*.

scale

REAL for psgebal and pcgebal

DOUBLE PRECISION for pdgebal and pzgebal

(global) array of size *n*.

Details of the permutations and scaling factors applied to `a`. If *pj* is the index of the row and column interchanged with row and column *j* and *dj* is the scaling factor applied to row and column *j*, then

`scale`(*j*) = *pj* for *j* = 1,...,`ilo`-1, `ihi`+1,..., n

`scale`(*j*) = *dj* for *j* = `ilo`,...,`ihi`

The order in which the interchanges are made is `n` to `ihi`+1, then 1 to `ilo`-1.

`info` (global) `INTEGER`

= 0: successful exit.

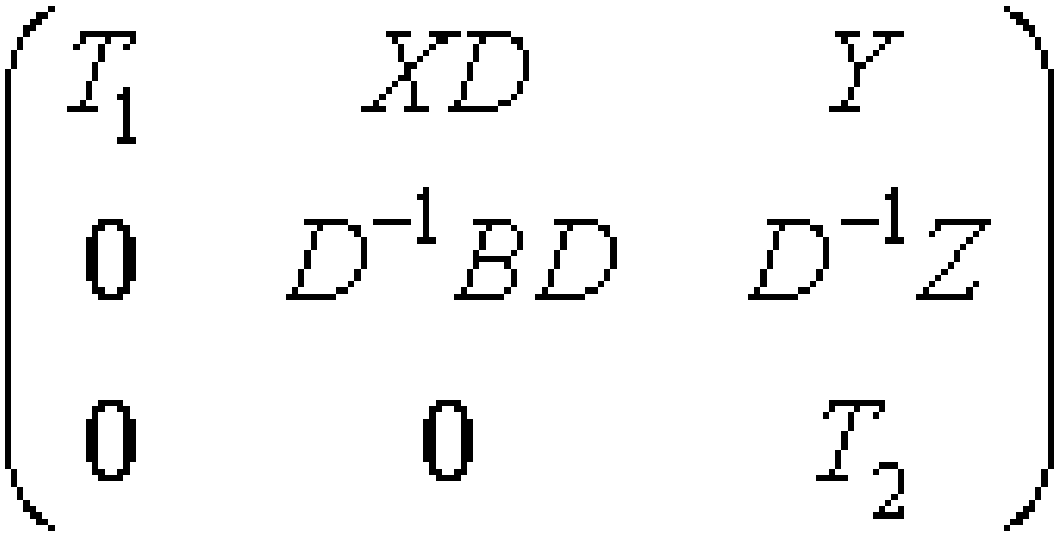
< 0: if `info` = -*i*, the *i*-th argument had an illegal value.

Application Notes

The permutations consist of row and column interchanges which put the matrix in the form

$$PAP = \begin{pmatrix} T_1 & X & Y \\ 0 & B & Z \\ 0 & 0 & T_2 \end{pmatrix}$$

where *T1* and *T2* are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices `ilo` and `ihi` mark the starting and ending columns of the submatrix B. Balancing consists of applying a diagonal similarity transformation $D^{-1}BD$ to make the 1-norms of each row of *B* and its corresponding column nearly equal. The output matrix is



Information about the permutations *P* and the diagonal matrix *D* is returned in the vector `scale`.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?gebd2

Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).

Syntax

```
call psgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pdgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pcgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pzgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
```

Description

The `p?gebd2`routine reduces a real/complex general *m*-by-*n* distributed matrix sub(*A*) = *A*`(ia:ia+m-1, ja:ja+n-1)` to upper or lower bidiagonal form *B* by an orthogonal/unitary transformation:

```
Q'*sub(A)*P = B.
```

If $m \geq n$, *B* is the upper bidiagonal; if $m<n$, *B* is the lower bidiagonal.

Input Parameters

`m`	(global) `INTEGER`. The number of rows of the distributed matrix sub(*A*). $(m \geq 0)$.
`n`	(global) `INTEGER`. The number of columns in the distributed matrix sub(*A*). ($n \geq 0$).
`a`	(local).

REAL for psgebd2

DOUBLE PRECISION for pdgebd2

COMPLEX for pcgebd2

COMPLEX*16 for pzgebd2.

Pointer into the local memory to an array of size (*lld_a*, LOC_c(*ja*+*n*-1)).

On entry, this array contains the local pieces of the general distributed matrix sub(*A*).

ia, *ja* (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A.

work (local).

REAL for psgebd2

DOUBLE PRECISION for pdgebd2

COMPLEX for pcgebd2

COMPLEX*16 for pzgebd2.

This is a workspace array of size *lwork*.

lwork (local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least *lwork* ≥ max(*mpa*0, *nqa*0),

where *nb* = *mb_a* = *nb_a*, *iroffa* = mod(*ia*-1, *nb*),

iarow = indxg2p(*ia*, *nb*, *myrow*, *rsrc_a*, *nprow*),

iacol = indxg2p(*ja*, *nb*, *mycol*, *csrc_a*, *npcol*),

*mpa*0 = numroc(*m*+*iroffa*, *nb*, *myrow*, *iarow*, *nprow*),

*nqa*0 = numroc(*n*+*icoffa*, *nb*, *mycol*, *iacol*, *npcol*).

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a (local).

On exit, if *m* ≥ *n*, the diagonal and the first superdiagonal of sub(*A*) are overwritten with the upper bidiagonal matrix *B*; the elements below the diagonal, with the array *tauq*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors, and the elements above the first superdiagonal, with the array *taup*, represent the orthogonal matrix *P* as a

product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix *B*; the elements below the first subdiagonal, with the array *tauq*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors, and the elements above the diagonal, with the array *taup*, represent the orthogonal matrix *P* as a product of elementary reflectors. See *Applications Notes* below.

d (local)

REAL for psgebd2

DOUBLE PRECISION for pdgebd2

COMPLEX for pcgebd2

COMPLEX*16 for pzgebd2.

Array of size $LOCc(ja+\min(m,n)-1)$ if $m \geq n$; $LOCr(ia+\min(m,n)-1)$ otherwise. The distributed diagonal elements of the bidiagonal matrix *B*: $d(i) = a(i,i)$. *d* is tied to the distributed matrix *A*.

e (local)

REAL for psgebd2

DOUBLE PRECISION for pdgebd2

COMPLEX for pcgebd2

COMPLEX*16 for pzgebd2.

Array of size $LOCc(ja+\min(m,n)-1)$ if $m \geq n$; $LOCr(ia+\min(m,n)-2)$ otherwise. The distributed diagonal elements of the bidiagonal matrix *B*:

if $m \geq n$, $e(i) = a(i, i+1)$ for $i = 1, 2, \ldots, n-1$;

if $m < n$, $e(i) = a(i+1, i)$ for $i = 1, 2, \ldots, m-1$. *e* is tied to the distributed matrix *A*.

tauq (local).

REAL for psgebd2

DOUBLE PRECISION for pdgebd2

COMPLEX for pcgebd2

COMPLEX*16 for pzgebd2.

Array of size $LOCc(ja+\min(m,n)-1)$. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Q*. *tauq* is tied to the distributed matrix *A*.

taup (local).

REAL for psgebd2

DOUBLE PRECISION for pdgebd2

COMPLEX for pcgebd2

COMPLEX*16 for pzgebd2.

Array of size `LOCr(ia+min(m,n)-1)`. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *P*. *taup* is tied to the distributed matrix *A*.

work

On exit, `work(1)` returns the minimal and optimal *lwork*.

info

(local)

`INTEGER`.

If `info = 0`, the execution is successful.

if `info < 0`: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then `info` = - (*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then `info` = -*i*.

Application Notes

The matrices *Q* and *P* are represented as products of elementary reflectors:

If `m≥n`,

`Q = H(1)*H(2)*...*H(n), and P = G(1)*G(2)*...*G(n-1)`

Each *H*(i) and *G*(i) has the form:

`H(i) = I - tauq*v*v', and G(i) = I - taup*u*u',`

where *tauq* and *taup* are real/complex scalars, and *v* and *u* are real/complex vectors. `v(1: i-1) = 0`, `v(i) = 1`, and `v(i+i:m)` is stored on exit in

`A(ia+i-ia+m-1, ja+i-1);`

`u(1:i) = 0, u(i+1) = 1`, and `u(i+2:n)` is stored on exit in `A(ia+i-1, ja+i+1:ja+n-1);`

tauq is stored in `tauq(ja+i-1)` and *taup* in `taup(ia+i-1)`.

If `m < n`,

`v(1: i) = 0, v(i+1) = 1`, and `v(i+2:m)` is stored on exit in `A(ia+i+1: ia+m-1, ja+i-1);`

`u(1: i-1) = 0, u(i) = 1`, and `u(i+1 :n)` is stored on exit in `A(ia+i-1,ja+i:ja+n-1);`

tauq is stored in `tauq(ja+i-1)` and *taup* in `taup(ia+i-1)`.

The contents of sub(*A*) on exit are illustrated by the following examples:

$m = 6\ and\ n = 5 (m > n):$

$$\begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}$$

$m = 5\ and\ n = 6 (m < n):$

$$\begin{bmatrix} d & u1 & u1 & u1 & u1 & u1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}$$

where *d* and *e* denote diagonal and off-diagonal elements of *B*, *vi* denotes an element of the vector defining `H(i)`, and *ui* an element of the vector defining `G(i)`.

p?gehd2

Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm).

Syntax

```
call psgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pdgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pcgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pzgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The p?gehd2routine reduces a real/complex general distributed matrix sub(*A*) to upper Hessenberg form *H* by an orthogonal/unitary similarity transformation: *Q*'*sub(*A*)**Q* = *H*, where sub(*A*) = *A*(*ia*+*n*-1 :*ia*+*n*-1, *ja*+*n*-1 :*ja*+*n*-1).

Input Parameters

n — (global) INTEGER. The order of the distributed submatrix *A*. (*n*≥ 0).

ilo, *ihi* — (global) INTEGER. It is assumed that the matrix sub(*A*) is already upper triangular in rows *ia*:*ia*+*ilo*-2 and *ia*+*ihi*:*ia*+*n*-1 and columns *ja*:*ja*+*jlo*-2 and *ja*+*jhi*:*ja*+*n*-1. See *Application Notes* for further information.

If *n*≥ 0, 1 ≤ *ilo* ≤ *ihi* ≤ *n*; otherwise set *ilo* = 1, *ihi* = *n*.

a — (local).

REAL for psgehd2

DOUBLE PRECISION for pdgehd2

COMPLEX for pcgehd2

COMPLEX*16 for pzgehd2.

Pointer into the local memory to an array of size (*lld_a*, LOC_c(*ja*+*n*-1)).

On entry, this array contains the local pieces of the *n*-by-*n* general distributed matrix sub(*A*) to be reduced.

ia, *ja* — (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of sub(*A*), respectively.

desca — (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

work — (local).

REAL for psgehd2

DOUBLE PRECISION for pdgehd2

COMPLEX for pcgehd2

COMPLEX*16 for pzgehd2.

This is a workspace array of size *lwork*.

lwork (local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least *lwork*≥*nb* + max(*npa*0, *nb*), where *nb* = *mb_a* = *nb_a*, *iroffa* = mod(*ia*-1, *nb*), *iarow* = indxg2p (*ia*, *nb*, *myrow*, *rsrc_a*, *nprow*),*npa*0 = numroc(*ihi* +*iroffa*, *nb*, *myrow*, *iarow*, *nprow*).

indxg2p and numroc are ScaLAPACK tool functions;*myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a (local). On exit, the upper triangle and the first subdiagonal of sub(*A*) are overwritten with the upper Hessenberg matrix *H*, and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors. (see *Application Notes* below).

tau (local).

REAL for psgehd2

DOUBLE PRECISION for pdgehd2

COMPLEX for pcgehd2

COMPLEX*16 for pzgehd2.

Array of size *LOCc*(*ja*+*n*-2) The scalar factors of the elementary reflectors (see *Application Notes* below). Elements *ja*:*ja*+*ilo*-2 and *ja*+*ihi*:*ja*+*n*-2 of the global vector *tau* are set to zero. *tau* is tied to the distributed matrix *A*.

work On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local) INTEGER.

If *info* = 0, the execution is successful.

if *info* < 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = - (*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrix *Q* is represented as a product of (*ihi-ilo*) elementary reflectors

```
Q = H(ilo)*H(ilo+1)*...*H(ihi-1).
```

Each *H*(*i*) has the form

```
H(i) = I - tau*v*v',
```

where *tau* is a real/complex scalar, and *v* is a real/complex vector with `v(1: i)=0`, `v(i+1)=1` and `v(ihi +1:n)=0`; `v(i+2:ihi)` is stored on exit in `A(ia+ilo+i:ia+ihi-1, ia+ilo+i-2)`, and *tau* in `tau(ja+ilo +i-2)`.

The contents of `A(ia:ia+n-1, ja:ja+n-1)` are illustrated by the following example, with `n = 7`, `ilo = 2` and `ihi = 6`:

on entry

$$\begin{bmatrix} a & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & & & & & & a \end{bmatrix}$$

on exit

$$\begin{bmatrix} a & a & h & h & h & h & a \\ & a & h & h & h & h & a \\ & h & h & h & h & h & h \\ & v2 & h & h & h & h & h \\ & v2 & v3 & h & h & h & h \\ & v2 & v3 & v4 & h & h & h \\ & & & & & & a \end{bmatrix}$$

where *a* denotes an element of the original matrix sub(*A*), *h* denotes a modified element of the upper Hessenberg matrix *H*, and *vi* denotes an element of the vector defining `H(ja+ilo+i-2)`.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?gelq2

Computes an LQ factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The `p?gelq2`routine computes an *LQ* factorization of a real/complex distributed *m*-by-*n* matrix `sub(A) = A(ia:ia+m-1, ja:ja+n-1) = L*Q`.

Input Parameters

`m` (global) `INTEGER`.

The number of rows of the distributed matrix sub(*A*). `(m≥0)`.

`n` (global) `INTEGER`.

The number of columns of the distributed matrix sub(*A*). `(n≥0)`.

`a` (local).

REAL for psgelq2

DOUBLE PRECISION for pdgelq2

COMPLEX for pcgelq2

COMPLEX*16 for pzgelq2.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)).

On entry, this array contains the local pieces of the *m*-by-*n* distributed matrix sub(*A*) which is to be factored.

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of sub(*A*), respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

work

(local).

REAL for psgelq2

DOUBLE PRECISION for pdgelq2

COMPLEX for pcgelq2

COMPLEX*16 for pzgelq2.

This is a workspace array of size *lwork*.

lwork

(local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least *lwork*≥*nq*0 + max(1, *mp*0),

where *iroff* = mod(*ia*-1, *mb_a*), *icoff* = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),

*mp*0 = numroc(*m*+*iroff*, *mb_a*, *myrow*, *iarow*, *nprow*),

*nq*0 = numroc(*n*+*icoff*, *nb_a*, *mycol*, *iacol*, *npcol*),

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a

(local).

On exit, the elements on and below the diagonal of sub(*A*) contain the *m* by min(*m*,*n*) lower trapezoidal matrix *L* (*L* is lower triangular if *m* ≤ *n*); the elements above the diagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors (see *Application Notes* below).

tau	(local).
	`REAL` for `psgelq2`
	`DOUBLE PRECISION` for `pdgelq2`
	`COMPLEX` for `pcgelq2`
	`COMPLEX*16` for `pzgelq2`.
	Array of size *LOCr*(*ia*+min(*m*, *n*)-1). This array contains the scalar factors of the elementary reflectors. *tau* is tied to the distributed matrix *A*.

work	On exit, *work*(1) returns the minimal and optimal *lwork*.
info	(local) `INTEGER`. If *info* = 0, the execution is successful. if *info* < 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = - (*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

Q =*H*(*ia*+*k*-1)**H*(*ia*+*k*-2)*. . . **H*(*ia*) for real flavors, *Q* =(*H*(*ia*+*k*-1))^H*(*H*(*ia*+*k*-2))^H...*(*H*(*ia*))^H for complex flavors,

where *k* = min(*m*,*n*).

Each *H*(*i*) has the form

H(*i*) = *I* - *tau***v***v*'

where *tau* is a real/complex scalar, and *v* is a real/complex vector with *v*(1: *i*-1) = 0 and *v*(*i*) = 1; *v*(*i*+1: *n*) (for real flavors) or conjg(*v*(*i*+1: *n*)) (for complex flavors) is stored on exit in *A*(*ia*+*i*-1,*ja*+*i*:*ja*+*n*-1), and *tau* in *tau*(*ia*+*i*-1).

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?geql2

Computes a QL factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The p?geql2routine computes a *QL* factorization of a real/complex distributed *m*-by-*n* matrix sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1)= *Q* **L*.

Input Parameters

m	(global) `INTEGER`.

The number of rows in the distributed matrix sub(*A*). (*m*≥ 0).

n

(global) INTEGER.

The number of columns in the distributed matrix sub(*A*). (*n*≥ 0).

a

(local).

REAL for psgeql2

DOUBLE PRECISION for pdgeql2

COMPLEX for pcgeql2

COMPLEX*16 for pzgeql2.

Pointer into the local memory to an array of size (*lld_a*, $LOC_c(ja+n-1)$).

On entry, this array contains the local pieces of the *m*-by-*n* distributed matrix sub(*A*) which is to be factored.

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of sub(*A*), respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A.

work

(local).

REAL for psgeql2

DOUBLE PRECISION for pdgeql2

COMPLEX for pcgeql2

COMPLEX*16 for pzgeql2.

This is a workspace array of size *lwork*.

lwork

(local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least lwork≥*mp*0 + max(1, *nq*0),

where *iroff* = mod(*ia*-1, *mb_a*), *icoff* = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),

*mp*0 = numroc(*m*+*iroff*, *mb_a*, *myrow*, *iarow*, *nprow*),

*nq*0 = numroc(*n*+*icoff*, *nb_a*, *mycol*, *iacol*, *npcol*),

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a

(local).

On exit,

if $m \geq n$, the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the n-by-n lower triangular matrix L;

if $m \leq n$, the elements on and below the $(n-m)$-th superdiagonal contain the m-by-n lower trapezoidal matrix L; the remaining elements, with the array *tau*, represent the orthogonal/ unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

tau (local).

`REAL` for `psgeql2`

`DOUBLE PRECISION` for `pdgeql2`

`COMPLEX` for `pcgeql2`

`COMPLEX*16` for `pzgeql2`.

Array of size *LOCc*(*ja*+*n*-1). This array contains the scalar factors of the elementary reflectors. *tau* is tied to the distributed matrix *A*.

work On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local). `INTEGER`.

If *info* = 0, the execution is successful. if *info* < 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrix Q is represented as a product of elementary reflectors

Q = *H*(*ja*+*k*-1)*...**H*(*ja*+1)**H*(*ja*), where *k* = min(*m*,*n*).

Each *H*(*i*) has the form

H(*i*) = *I*- *tau* **v***v*'

where *tau* is a real/complex scalar, and *v* is a real/complex vector with *v*(*m*-*k*+*i*+1: *m*) = 0 and *v*(*m*-*k*+*i*) = 1; *v*(1: *m*-*k*+*i*-1) is stored on exit in *A*(*ia*:*ia*+*m*-*k*+*i*-2, *ja*+*n*-*k*+*i*-1), and *tau* in *tau*(*ja*+*n*-*k*+*i*-1).

p?geqr2

Computes a QR factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The p?geqr2routine computes a *QR* factorization of a real/complex distributed *m*-by-*n* matrix sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1)= *Q***R*.

Input Parameters

m — (global) INTEGER.

The number of rows in the distributed matrix sub(*A*). (*m*≥0).

n — (global) INTEGER. The number of columns in the distributed matrix sub(*A*). (*n*≥0).

a — (local).

REAL for psgeqr2

DOUBLE PRECISION for pdgeqr2

COMPLEX for pcgeqr2

COMPLEX*16 for pzgeqr2.

Pointer into the local memory to an array of size (*lld_a*, LOC_c(*ja*+*n*-1)).

On entry, this array contains the local pieces of the *m*-by-*n* distributed matrix sub(*A*) which is to be factored.

ia, *ja* — (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of sub(*A*), respectively.

desca — (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A.

work — (local).

REAL for psgeqr2

DOUBLE PRECISION for pdgeqr2

COMPLEX for pcgeqr2

COMPLEX*16 for pzgeqr2.

This is a workspace array of size *lwork*.

lwork — (local or global) INTEGER.

The size of the array *work*.

l*work* is local input and must be at least *lwork*≥*mp*0+max(1, *nq*0),

where *iroff* = mod(*ia*-1, *mb_a*), *icoff* = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),

*mp*0 = numroc(*m*+*iroff*, *mb_a*, *myrow*, *iarow*, *nprow*),

*nq*0 = numroc(*n*+*icoff*, *nb_a*, *mycol*, *iacol*, *npcol*).

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a (local).

On exit, the elements on and above the diagonal of sub(*A*) contain the min(*m*,*n*) by *n* upper trapezoidal matrix *R* (*R* is upper triangular if *m*≥*n*); the elements below the diagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors (see *Application Notes* below).

tau (local).

REAL for psgeqr2

DOUBLE PRECISION for pdgeqr2

COMPLEX for pcgeqr2

COMPLEX*16 for pzgeqr2.

Array of size *LOCc*(*ja*+min(*m*,*n*)-1). This array contains the scalar factors of the elementary reflectors. *tau* is tied to the distributed matrix *A*.

work On exit, work(1) returns the minimal and optimal *lwork*.

info (local) INTEGER.

If info = 0, the execution is successful. if *info* < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then info = - (*i**100+*j*),

if the *i*-th argument is a scalar and had an illegal value, then info = -*i*.

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

Q = *H*(*ja*)**H*(*ja*+1)*. . .* *H*(*ja*+*k*-1), where *k* = min(*m*,*n*).

Each *H*(*i*) has the form

H(*j*)= *I* - *tau***v***v*',

where *tau* is a real/complex scalar, and *v* is a real/complex vector with *v*(1: *i*-1) = 0 and *v*(*i*) = 1; *v*(*i*+1: *m*) is stored on exit in *A*(*ia*+*i*:*ia*+*m*-1, *ja*+*i*-1), and *tau* in *tau*(*ja*+*i*-1).

p?gerq2

Computes an RQ factorization of a general rectangular matrix (unblocked algorithm).

Syntax

call psgerq2(*m*, *n*, *a*, *ia*, *ja*, *desca*, *tau*, *work*, *lwork*, *info*)

```
call pdgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The p?gerq2routine computes an *RQ* factorization of a real/complex distributed *m*-by-*n* matrix sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1) = *R***Q*.

Input Parameters

m — (global) INTEGER. The number of rows in the distributed matrix sub(*A*). (*m*≥0).

n — (global) INTEGER. The number of columns in the distributed matrix sub(*A*). (*n*≥0).

a — (local).

REAL for psgerq2

DOUBLE PRECISION for pdgerq2

COMPLEX for pcgerq2

COMPLEX*16 for pzgerq2.

Pointer into the local memory to an array of size (*lld_a*, LOC_c(*ja*+*n*-1)).

On entry, this array contains the local pieces of the *m*-by-*n* distributed matrix sub(*A*) which is to be factored.

ia, *ja* — (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of sub(*A*), respectively.

desca — (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A.

work — (local).

REAL for psgerq2

DOUBLE PRECISION for pdgerq2

COMPLEX for pcgerq2

COMPLEX*16 for pzgerq2.

This is a workspace array of size *lwork*.

lwork — (local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least *lwork*≥*nq*0 + max(1, *mp*0), where

iroff = mod(*ia*-1, *mb_a*), *icoff* = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*), *mp*0 = numroc(*m*+*iroff*, *mb_a*, *myrow*, *iarow*, *nprow*),

*nq*0 = numroc(*n*+*icoff*, *nb_a*, *mycol*, *iacol*, *npcol*),

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a (local).

On exit,

if *m* ≤ *n*, the upper triangle of *A*(*ia*+*m*-*n*:*ia*+*m*-*1*, *ja*:*ja*+*n*-*1*) contains the *m*-by-*m* upper triangular matrix *R*;

if *m* ≥ *n*, the elements on and above the (*m*-*n*)-th subdiagonal contain the *m*-by-*n* upper trapezoidal matrix *R*; the remaining elements, with the array *tau*, represent the orthogonal/ unitary matrix *Q* as a product of elementary reflectors (see *Application Notes* below).

tau (local).

REAL for psgerq2

DOUBLE PRECISION for pdgerq2

COMPLEX for pcgerq2

COMPLEX*16 for pzgerq2.

Array of size *LOCr*(*ia*+*m* -1). This array contains the scalar factors of the elementary reflectors. *tau* is tied to the distributed matrix *A*.

work On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local) INTEGER.

If *info* = 0, the execution is successful.

if *info* < 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = - (*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

Q = *H*(*ia*)**H*(*ia*+1)*...**H*(*ia*+*k*-1) for real flavors,

$Q = (H(ia))^{H}*(H(ia+1))^{H}...*(H(ia+k-1))^{H}$ for complex flavors,

where *k* = min(*m*, *n*).

Each *H*(*i*) has the form

H(*i*) = *I* - *tau***v***v*',

where *tau* is a real/complex scalar, and *v* is a real/complex vector with *v*(*n*-*k*+*i*+1:*n*) = 0 and *v*(*n*-*k*+*i*) = 1; *v*(1:*n*-*k*+*i*-1) for real flavors or conjg(*v*(1:*n*-*k*+*i*-1)) for complex flavors is stored on exit in *A*(*ia*+*m*-*k*+*i*-1, *ja*:*ja*+*n*-*k*+*i*-2), and *tau* in *tau*(*ia*+*m*-*k*+*i*-1).

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?getf2

Computes an LU factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).

Syntax

```
call psgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pdgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pcgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pzgetf2(m, n, a, ia, ja, desca, ipiv, info)
```

Description

The p?getf2routine computes an *LU* factorization of a general *m*-by-*n* distributed matrix sub(*A*) = `A(ia:ia+m-1, ja:ja+n-1)` using partial pivoting with row interchanges.

The factorization has the form `sub(A) = P * L* U`, where *P* is a permutation matrix, *L* is lower triangular with unit diagonal elements (lower trapezoidal if $m>n$), and *U* is upper triangular (upper trapezoidal if $m < n$). This is the right-looking Parallel Level 2 BLAS version of the algorithm.

Input Parameters

m

(global) INTEGER.

The number of rows in the distributed matrix sub(*A*). $(m\geq 0)$.

n

(global) INTEGER. The number of columns in the distributed matrix sub(*A*). $(nb\_a - \mathrm{mod}(ja-1, nb\_a)\geq n\geq 0)$.

a

(local).

REAL for psgetf2

DOUBLE PRECISION for pdgetf2

COMPLEX for pcgetf2

COMPLEX*16 for pzgetf2.

Pointer into the local memory to an array of size $(lld\_a, LOC_c(ja+n-1))$.

On entry, this array contains the local pieces of the *m*-by-*n* distributed matrix sub(*A*).

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

Output Parameters

ipiv (local) INTEGER.

Array of size (*LOCr(m_a) + mb_a*). This array contains the pivoting information. *ipiv(i)* -> The global row that local row *i* was swapped with. This array is tied to the distributed matrix *A*.

info (local). INTEGER.

If *info* = 0: successful exit.

If *info* < 0:

- if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*),
- if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* > 0: If *info* = *k*, the matrix element *U*(*ia*+*k*-1, *ja*+*k*-1) is exactly zero. The factorization has been completed, but the factor *U* is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?labrd

Reduces the first nb rows and columns of a general rectangular matrix A to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.

Syntax

```
call pslabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx, y, iy, jy, descy, work)
call pdlabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx, y, iy, jy, descy, work)
call pclabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx, y, iy, jy, descy, work)
call pzlabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx, y, iy, jy, descy, work)
```

Description

The p?labrdroutine reduces the first *nb* rows and columns of a real/complex general *m*-by-*n* distributed matrix sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1) to upper or lower bidiagonal form by an orthogonal/unitary transformation *Q'* A * P*, and returns the matrices *X* and *Y* necessary to apply the transformation to the unreduced part of sub(*A*).

If *m* ≥*n*, sub(*A*) is reduced to upper bidiagonal form; if *m* < *n*, sub(*A*) is reduced to lower bidiagonal form.

This is an auxiliary routine called by p?gebrd.

Input Parameters

m

(global) INTEGER. The number of rows in the distributed matrix sub(*A*). (*m*≥ 0).

n

(global) INTEGER. The number of columns in the distributed matrix sub(*A*). (*n* ≥ 0).

nb

(global) INTEGER.

The number of leading rows and columns of sub(*A*) to be reduced.

a

(local).

REAL for pslabrd

DOUBLE PRECISION for pdlabrd

COMPLEX for pclabrd

COMPLEX*16 for pzlabrd.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)).

On entry, this array contains the local pieces of the general distributed matrix sub(*A*).

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

ix, *jx*

(global) INTEGER. The row and column indices in the global matrix *X* indicating the first row and the first column of the matrix sub(*X*), respectively.

descx

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *X*.

iy, *jy*

(global) INTEGER. The row and column indices in the global matrix *Y* indicating the first row and the first column of the matrix sub(*Y*), respectively.

descy

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Y*.

work

(local).

REAL for pslabrd

DOUBLE PRECISION for pdlabrd

COMPLEX for pclabrd

COMPLEX*16 for pzlabrd

Workspace array of size*lwork*.

lwork ≥ *nb_a* + *nq*,

with *nq* = numroc(*n*+mod(*ia*-1, *nb_y*), *nb_y*, *mycol*, *iacol*, *npcol*)

iacol = indxg2p (*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*)

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

a (local)

On exit, the first *nb* rows and columns of the matrix are overwritten; the rest of the distributed matrix sub(*A*) is unchanged.

If $m \geq n$, elements on and below the diagonal in the first *nb* columns, with the array *tauq*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors; and elements above the diagonal in the first *nb* rows, with the array *taup*, represent the orthogonal/unitary matrix *P* as a product of elementary reflectors.

If $m < n$, elements below the diagonal in the first *nb* columns, with the array *tauq*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors, and elements on and above the diagonal in the first *nb* rows, with the array *taup*, represent the orthogonal/unitary matrix *P* as a product of elementary reflectors. See *Application Notes* below.

d (local).

REAL for pslabrd

DOUBLE PRECISION for pdlabrd

COMPLEX for pclabrd

COMPLEX*16 for pzlabrd

Array of size *LOCr*(*ia*+min(*m*,*n*)-1) if $m \geq n$; *LOCc*(*ja*+min(*m*,*n*)-1) otherwise. The distributed diagonal elements of the bidiagonal distributed matrix *B*:

d(*i*) = *A*(*ia*+*i*-1, *ja*+*i*-1).

d is tied to the distributed matrix *A*.

e (local).

REAL for pslabrd

DOUBLE PRECISION for pdlabrd

COMPLEX for pclabrd

COMPLEX*16 for pzlabrd

Array of size *LOCr*(*ia*+min(*m*,*n*)-1) if $m \geq n$; *LOCc*(*ja*+min(*m*,*n*)-2) otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix *B*:

if $m \geq n$, *E*(*i*) = *A*(*ia*+*i*-1, *ja*+*i*) for *i* = 1, 2, ..., *n*-1;

if $m<n$, *E*(*i*) = *A*(*ia*+*i*, *ja*+*i*-1) for *i* = 1, 2, ..., *m*-1.

e is tied to the distributed matrix *A*.

tauq, *taup* (local).

REAL for pslabrd

DOUBLE PRECISION for pdlabrd

COMPLEX for pclabrd

COMPLEX*16 for pzlabrd

Array size *LOCc*(*ja*+min(*m*, *n*)-1) for *tauq*, size *LOCr*(*ia*+min(*m*, *n*)-1) for *taup*. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Q* for *tauq*, *P* for *taup*. *tauq* and *taup* are tied to the distributed matrix *A*. See *Application Notes* below.

x (local)

REAL for pslabrd

DOUBLE PRECISION for pdlabrd

COMPLEX for pclabrd

COMPLEX*16 for pzlabrd

Pointer into the local memory to an array of size *lld_x* by *nb*. On exit, the local pieces of the distributed *m*-by-*nb* matrix *X*(*ix*:*ix*+*m*-1, *jx*:*jx*+*nb*-1) required to update the unreduced part of sub(*A*).

y (local).

REAL for pslabrd

DOUBLE PRECISION for pdlabrd

COMPLEX for pclabrd

COMPLEX*16 for pzlabrd

Pointer into the local memory to an array of size *lld_y* by *nb*. On exit, the local pieces of the distributed *n*-by-*nb* matrix *Y*(*iy*:*iy*+*n*-1, *jy*:*jy*+*nb*-1) required to update the unreduced part of sub(*A*).

Application Notes

The matrices *Q* and *P* are represented as products of elementary reflectors:

Q = *H*(1)**H*(2)*...**H*(*nb*), and *P* = *G*(1)**G*(2)*...**G*(*nb*)

Each *H*(i) and *G*(i) has the form:

H(i) = *I* - *tauq***v***v*', and *G*(i) = *I* - *taup***u***u*',

where *tauq* and *taup* are real/complex scalars, and *v* and *u* are real/complex vectors.

If *m* ≥ *n*, *v*(1: *i*-1) = 0, *v*(*i*) = 1, and *v*(*i*:*m*) is stored on exit in

A(*ia*+*i*-1:*ia*+*m*-1, *ja*+*i*-1); *u*(1:*i*) = 0, *u*(*i*+1) = 1, and *u*(*i*+1:*n*) is stored on exit in *A*(*ia*+*i*-1, *ja*+*i*:*ja*+*n*-1); *tauq* is stored in *tauq*(*ja*+*i*-1) and *taup* in *taup*(*ia*+*i*-1).

If *m* < *n*, *v*(1: *i*) = 0, *v*(*i*+1) = 1, and *v*(*i*+1:*m*) is stored on exit in

A(*ia*+*i*+1:*ia*+*m*-1, *ja*+*i*-1); *u*(1:*i*-1) = 0, *u*(*i*) = 1, and *u*(*i*:*n*) is stored on exit in *A*(*ia*+*i*-1, *ja*+*i*:*ja*+*n*-1); *tauq* is stored in *tauq*(*ja*+*i*-1) and *taup* in *taup*(*ia*+*i*-1). The elements of the vectors *v* and *u* together form the *m*-by-*nb* matrix *V* and the *nb*-by-*n* matrix *U*' which are necessary, with *X* and *Y*, to apply the transformation to the unreduced part of the matrix, using a block update of the form: sub(*A*) := sub(*A*) - *V***Y*' - *X***U*'. The contents of sub(*A*) on exit are illustrated by the following examples with *nb* = 2:

$m = 6$ **and** $n = 5 (m > n)$:

$$\begin{bmatrix} 1 & 1 & u1 & u1 & u1 \\ v1 & 1 & 1 & u2 & u2 \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix}$$

$m = 5$ **and** $n = 6 (m < n)$ **:**

$$\begin{bmatrix} 1 & u1 & u1 & u1 & u1 & u1 \\ 1 & 1 & u2 & u2 & u2 & u2 \\ v1 & 1 & a & a & a & a \\ v1 & v2 & a & a & a & a \\ v1 & v2 & a & a & a & a \end{bmatrix}$$

where *a* denotes an element of the original matrix which is unchanged, *vi* denotes an element of the vector defining `H(i)`, and *ui* an element of the vector defining `G(i)`.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lacon

Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.

Syntax

```
call pslacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pdlacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pclacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pzlacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
```

Description

The `p?lacon`routine estimates the 1-norm of a square, real/unitary distributed matrix *A*. Reverse communication is used for evaluating matrix-vector products. *x* and *v* are aligned with the distributed matrix *A*, this information is implicitly contained within *iv*, *ix*, *descv*, and *descx*.

Input Parameters

n

(global) `INTEGER`. The length of the distributed vectors *v* and *x*. $n \geq 0$.

v

(local).

`REAL` for `pslacon`

`DOUBLE PRECISION` for `pdlacon`

`COMPLEX` for `pclacon`

`COMPLEX*16` for `pzlacon`.

Pointer into the local memory to an array of size *LOCr*(*n*+mod(*iv*-1, *mb_v*)). On the final return, `v = a*w`, where *est* = norm(*v*)/norm(*w*) (*w* is not returned).

iv, *jv*	(global) INTEGER. The row and column indices in the global matrix *V* indicating the first row and the first column of the submatrix *V*, respectively.
descv	(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix V.
x	(local). REAL for pslacon DOUBLE PRECISION for pdlacon COMPLEX for pclacon COMPLEX*16 for pzlacon. Pointer into the local memory to an array of size *LOCr*(*n*+mod(*ix*-1, *mb_x*)).
ix, *jx*	(global) INTEGER. The row and column indices in the global matrix *X* indicating the first row and the first column of the submatrix *X*, respectively.
descx	(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix X.
isgn	(local). INTEGER. Array of size *LOCr*(*n*+mod(*ix*-1, *mb_x*)). *isgn* is aligned with *x* and *v*.
kase	(local). INTEGER. On the initial call to p?lacon, *kase* should be 0.

Output Parameters

x	(local). On an intermediate return, X should be overwritten by *A***X*, if *kase*=1, *A*'**X*, if *kase*=2, p?lacon must be re-called with all the other parameters unchanged.
est	(global). REAL for single precision flavors DOUBLE PRECISION for double precision flavors
kase	(local) INTEGER. On an intermediate return, *kase* is 1 or 2, indicating whether *X* should be overwritten by *A*X,* or *A'*X*. On the final return from p?lacon, *kase* is again 0.

p?laconsb

Looks for two consecutive small subdiagonal elements.

Syntax

```
call pslaconsb(a, desca, i, l, m, h44, h33, h43h34, buf, lwork)
call pdlaconsb(a, desca, i, l, m, h44, h33, h43h34, buf, lwork)
call pclaconsb(a, desca, i, l, m, h44, h33, h43h34, buf, lwork)
```

```
call pzlaconsb(a, desca, i, l, m, h44, h33, h43h34, buf, lwork)
```

Description

The p?laconsbroutine looks for two consecutive small subdiagonal elements by analyzing the effect of starting a double shift *QR* iteration given by *h44*, *h33*, and *h43h34* to see if this process makes a subdiagonal negligible.

Input Parameters

a

(local) REAL for pslaconsb

DOUBLE PRECISION for pdlaconsb

COMPLEX for pclaconsb

DOUBLE COMPLEX for pzlaconsb

Array of size (*lld_a*,*LOCc*(*n_a*)). On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.

desca

(global and local) INTEGER.

Array of size *dlen_*. The array descriptor for the distributed matrix *A*.

i

(global) INTEGER.

The global location of the bottom of the unreduced submatrix of *A*. Unchanged on exit.

l

(global) INTEGER.

The global location of the top of the unreduced submatrix of *A*. Unchanged on exit.

h44, *h33*, *h43h34*

(global). REAL for pslaconsb

DOUBLE PRECISION for pdlaconsb

COMPLEX for pclaconsb

DOUBLE COMPLEX for pzlaconsb

These three values are for the double shift *QR* iteration.

lwork

(local) INTEGER.

This must be at least 7*ceil(ceil((*i*-l)/*mb_a*)/lcm(*nprow*, *npcol*)). Here lcm is the least common multiple and *nprow***npcol* is the logical grid size.

Output Parameters

m

(global). On exit, this yields the starting location of the *QR* double shift. This will satisfy:

$l \le m \le i-2$.

buf

(local).

REAL for pslaconsb

DOUBLE PRECISION for pdlaconsb

COMPLEX for pclaconsb

DOUBLE COMPLEX for pzlaconsb

Array of size *lwork*.

p?lacp2

Copies all or part of a distributed matrix to another distributed matrix.

Syntax

```
call pslacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pdlacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pclacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pzlacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
```

Description

The p?lacp2routine copies all or part of a distributed matrix *A* to another distributed matrix *B*. No communication is performed, p?lacp2 performs a local copy sub(*A*):= sub(*B*), where sub(*A*) denotes *A*(*ia*:*ia*+*m*-1, *a*:*ja*+*n*-1) and sub(*B*) denotes *B*(*ib*:*ib*+*m*-1, *jb*:*jb*+*n*-1).

p?lacp2 requires that only dimension of the matrix operands is distributed.

Input Parameters

uplo

(global) CHARACTER. Specifies the part of the distributed matrix sub(*A*) to be copied:

= 'U': Upper triangular part is copied; the strictly lower triangular part of sub(*A*) is not referenced;

= 'L': Lower triangular part is copied; the strictly upper triangular part of sub(*A*) is not referenced.

Otherwise: all of the matrix sub(*A*) is copied.

m

(global) INTEGER.

The number of rows in the distributed matrix sub(*A*). (*m*≥ 0).

n

(global) INTEGER.

The number of columns in the distributed matrix sub(*A*). (*n*≥ 0).

a

(local).

REAL for pslacp2

DOUBLE PRECISION for pdlacp2

COMPLEX for pclacp2

COMPLEX*16 for pzlacp2.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)).

On entry, this array contains the local pieces of the *m*-by-*n* distributed matrix sub(*A*).

ia, *ja*	(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of sub(*A*), respectively.
desca	(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.
ib, *jb*	(global) INTEGER. The row and column indices in the global matrix *B* indicating the first row and the first column of sub(*B*), respectively.
descb	(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

Output Parameters

b	(local). REAL for pslacp2 DOUBLE PRECISION for pdlacp2 COMPLEX for pclacp2 COMPLEX*16 for pzlacp2. Pointer into the local memory to an array of size (*lld_b*, *LOCc*(*jb*+*n*-1)). This array contains on exit the local pieces of the distributed matrix sub(*B*) set as follows: if *uplo* = 'U', *B*(*ib*+*i*-1, *jb*+*j*-1) = *A*(*ia*+*i*-1, *ja*+*j*-1), 1≤*i*≤*j*, 1≤*j*≤*n*; if *uplo* = 'L', *B*(*ib*+*i*-1, *jb*+*j*-1) = *A*(*ia*+*i*-1, *ja*+*j*-1), *j*≤*i*≤*m*, 1≤*j*≤*n*; otherwise, *B*(*ib*+*i*-1, *jb*+*j*-1) = *A*(*ia*+*i*-1, *ja*+*j*-1), 1≤*i*≤*m*, 1≤*j*≤*n*.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lacp3

Copies from a global parallel array into a local replicated array or vice versa.

Syntax

```
call pslacp3(m, i, a, desca, b, ldb, ii, jj, rev)
call pdlacp3(m, i, a, desca, b, ldb, ii, jj, rev)
call pclacp3(m, i, a, desca, b, ldb, ii, jj, rev)
call pzlacp3(m, i, a, desca, b, ldb, ii, jj, rev)
```

Description

This is an auxiliary routine that copies from a global parallel array into a local replicated array or vise versa. Note that the entire submatrix that is copied gets placed on one node or more. The receiving node can be specified precisely, or all nodes can receive, or just one row or column of nodes.

Product and Performance Information
Notice revision #20201201

Input Parameters

m

(global) INTEGER.

m is the order of the square submatrix that is copied.

m≥ 0. Unchanged on exit.

i

(global) INTEGER. *A*(*i*, *i*) is the global location that the copying starts from. Unchanged on exit.

a

(local) REAL for pslacp3

DOUBLE PRECISION for pdlacp3

COMPLEX for pclacp3

DOUBLE COMPLEX for pzlacp3

Array of size (*lld_a*,*LOCc*(*n_a*)). On entry, the parallel matrix to be copied into or from.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

b

(local)

REAL for pslacp3

DOUBLE PRECISION for pdlacp3

COMPLEX for pclacp3

DOUBLE COMPLEX for pzlacp3

Array of size (*lld_b*,*LOCc*(*m*)). If *rev* = 0, this is the global portion of the matrix *A*(*i*:*i*+*m*-1, *i*:*i*+*m*-1). If *rev* = 1, this is unchanged on exit.

ldb

(local)

INTEGER.

The leading dimension of *B*.

ii, *jj*

(global) INTEGER. By using *rev* 0 and 1, data can be sent out and returned again. If *rev* = 0, then *ii* is destination row index and *jj* is destination column index for the node(s) receiving the replicated *B*. If *ii* ≥ 0, *jj* ≥ 0, then node (*ii*, *jj*) receives the data. If *ii* = -1, *jj* ≥ 0, then all rows in column *jj* receive the data. If *ii* ≥ 0, *jj* = -1, then all cols in row *ii* receive the data. If *ii* = -1, *jj* = -1, then all nodes receive the data. If *rev* !=0, then *ii* is the source row index for the node(s) sending the replicated *B*.

rev

(global) INTEGER. Use *rev* = 0 to send global *A* into locally replicated *B* (on node (*ii*, *jj*)). Use *rev* != 0 to send locally replicated *B* from node (*ii*, *jj*) to its owner (which changes depending on its location in *A*) into the global *A*.

Output Parameters

a	On exit, if *rev* = 1, the copied data. Unchanged on exit if *rev* = 0.
b	If *rev* = 1, this is unchanged on exit.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lacpy

Copies all or part of one two-dimensional array to another.

Syntax

```
call pslacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pdlacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pclacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pzlacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
```

Description

The p?lacpyroutine copies all or part of a distributed matrix *A* to another distributed matrix *B*. No communication is performed, p?lacpy performs a local copy sub(*B*):= sub(*A*), where sub(*A*) denotes *A*(*ia*:*ia*+*m*-1,*ja*:*ja*+*n*-1) and sub(*B*) denotes *B*(*ib*:*ib*+*m*-1,*jb*:*jb*+*n*-1).

Input Parameters

uplo	(global) CHARACTER. Specifies the part of the distributed matrix sub(*A*) to be copied: = 'U': Upper triangular part; the strictly lower triangular part of sub(*A*) is not referenced; = 'L': Lower triangular part; the strictly upper triangular part of sub(*A*) is not referenced. Otherwise: all of the matrix sub(*A*) is copied.
m	(global) INTEGER. The number of rows in the distributed matrix sub(*A*). (*m*≥0).
n	(global) INTEGER. The number of columns in the distributed matrix sub(*A*). (*n*≥0).
a	(local). REAL for pslacpy DOUBLE PRECISION for pdlacpy COMPLEX for pclacpy COMPLEX*16 for pzlacpy. Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)).

	On entry, this array contains the local pieces of the distributed matrix sub(*A*).
ia, *ja*	(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.
desca	(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A.
ib, *jb*	(global) INTEGER. The row and column indices in the global matrix *B* indicating the first row and the first column of sub(*B*) respectively.
descb	(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A.

Output Parameters

b	(local). REAL for pslacpy DOUBLE PRECISION for pdlacpy COMPLEX for pclacpy COMPLEX*16 for pzlacpy. Pointer into the local memory to an array of size (*lld_b*, *LOCc*(*jb*+*n*-1)). This array contains on exit the local pieces of the distributed matrix sub(B) set as follows: if *uplo* = 'U', *B*(*ib*+*i*-1, *jb*+*j*-1) = *A*(*ia*+*i*-1, *ja*+*j*-1), 1≤*i*≤*j*, 1≤*j*≤*n*; if *uplo* = 'L', *B*(*ib*+*i*-1, *jb*+*j*-1) = *A*(*ia*+*i*-1, *ja*+*j*-1), *j*≤*i*≤*m*, 1≤*j*≤*n*; otherwise, *B*(*ib*+*i*-1, *jb*+*j*-1) = *A*(*ia*+*i*-1, *ja*+*j*-1), 1≤*i*≤*m*, 1≤*j*≤*n*.

p?laevswp

Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.

Syntax

```
call pslaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
call pdlaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
call pclaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
call pzlaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
```

Description

The p?laevswproutine moves the eigenvectors (potentially unsorted) from where they are computed, to a ScaLAPACK standard block cyclic array, sorted so that the corresponding eigenvalues are sorted.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

n (global) INTEGER.

The order of the matrix *A*. $n \geq 0$.

zin (local).

REAL for pslaevswp

DOUBLE PRECISION for pdlaevswp

COMPLEX for pclaevswp

COMPLEX*16 for pzlaevswp.

Array of size (*ldzi*, *nvs*(*iam*+2)). The eigenvectors on input. *iam* is a process rank from [0, *nprocs*) interval. Each eigenvector resides entirely in one process. Each process holds a contiguous set of *nvs*(*iam*+2) eigenvectors. The global number of the first eigenvector that the process holds is: ((sum for *i*=[1, *iam*+1] of *nvs*(*i*))+1).

ldzi (local)

INTEGER. The leading dimension of the *zin* array.

iz, *jz* (global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz (global and local) INTEGER

Array of size *dlen_*. The array descriptor for the distributed matrix Z.

nvs (global) INTEGER.

Array of size *nprocs*+1

nvs(*i*) = number of eigenvectors held by processes [0, *i*-1)

nvs(1) = number of eigenvectors held by processes [0, 1 -1) = 0

nvs(*nprocs*+1)= number of eigenvectors held by processes [0, *nprocs*)= total number of eigenvectors.

key (global) INTEGER.

Array of size *n*. Indicates the actual index (after sorting) for each of the eigenvectors.

rwork (local).

REAL for pslaevswp

DOUBLE PRECISION for pdlaevswp

COMPLEX for pclaevswp

COMPLEX*16 for pzlaevswp.

Array of size *lrwork*.

lrwork (local)

INTEGER. Size of *work.*

Output Parameters

z (local).

REAL for pslaevswp

DOUBLE PRECISION for pdlaevswp

COMPLEX for pclaevswp

COMPLEX*16 for pzlaevswp.

Array of global size *n*by *n* and of local size (*lld_z*, *nq*). The eigenvectors on output. The eigenvectors are distributed in a block cyclic manner in both dimensions, with a block size of *nb*.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lahrd

Reduces the first nb columns of a general rectangular matrix A so that elements below the k-th subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.

Syntax

```
call pslahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
call pdlahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
call pclahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
call pzlahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
```

Description

The p?lahrdroutine reduces the first *nb* columns of a real general *n*-by-(*n*-*k*+1) distributed matrix *A*(*ia*:*ia*+*n*-1 , *ja*:*ja*+*n*-*k*) so that elements below the *k*-th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation *Q'*A*Q*. The routine returns the matrices *V* and *T* which determine *Q* as a block reflector *I*-*V*T*V'*, and also the matrix *Y* = *A*V*T*.

This is an auxiliary routine called by p?gehrd. In the following comments sub(*A*) denotes *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1).

Input Parameters

n (global) INTEGER.

The order of the distributed matrix sub(*A*). *n* ≥ 0.

k (global) INTEGER.

The offset for the reduction. Elements below the *k*-th subdiagonal in the first *nb* columns are reduced to zero.

nb (global) INTEGER.

The number of columns to be reduced.

a (local).

REAL for pslahrd

DOUBLE PRECISION for pdlahrd

COMPLEX for pclahrd

COMPLEX*16 for pzlahrd.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*−*k*)). On entry, this array contains the local pieces of the *n*-by-(*n*−*k*+1) general distributed matrix *A*(*ia*:*ia*+*n*−1, *ja*:*ja*+*n*−*k*).

ia, *ja* (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

iy, *jy* (global) INTEGER. The row and column indices in the global matrix *Y* indicating the first row and the first column of the matrix sub(*Y*), respectively.

descy (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Y*.

work (local).

REAL for pslahrd

DOUBLE PRECISION for pdlahrd

COMPLEX for pclahrd

COMPLEX*16 for pzlahrd.

Array of size *nb*.

Output Parameters

a (local).

On exit, the elements on and above the *k*-th subdiagonal in the first *nb* columns are overwritten with the corresponding elements of the reduced distributed matrix; the elements below the *k*-th subdiagonal, with the array *tau*, represent the matrix *Q* as a product of elementary reflectors. The other columns of *A*(*ia*:*ia*+*n*−1, *ja*:*ja*+*n*−*k*) are unchanged. (See *Application Notes* below.)

tau (local)

REAL for pslahrd

DOUBLE PRECISION for pdlahrd

COMPLEX for pclahrd

COMPLEX*16 for pzlahrd.

Array of size *LOCc*(*ja*+*n*-2). The scalar factors of the elementary reflectors (see *Application Notes* below). *tau* is tied to the distributed matrix *A*.

t (local) REAL for pslahrd

`DOUBLE PRECISION` for `pdlahrd`

`COMPLEX` for `pclahrd`

`COMPLEX*16` for `pzlahrd`.

Array of size *nb_a*by *nb_a*. The upper triangular matrix *T*.

y (local).

`REAL` for `pslahrd`

`DOUBLE PRECISION` for `pdlahrd`

`COMPLEX` for `pclahrd`

`COMPLEX*16` for `pzlahrd`.

Pointer into the local memory to an array of size *lld_y*by *nb_a*. On exit, this array contains the local pieces of the *n*-by-*nb* distributed matrix *Y*. *lld_y* ≥ *LOCr*(`ia+n-1`).

Application Notes

The matrix *Q* is represented as a product of *nb* elementary reflectors

`Q = H(1)*H(2)*...*H(nb)`.

Each `H(i)` has the form

`H(i) = i-tau*v*v'`,

where *tau* is a real/complex scalar, and *v* is a real/complex vector with *v*(1: *i*+*k*-1)= 0, *v*(*i*+*k*)= 1; *v*(*i*+*k* +1:*n*) is stored on exit in *A*(*ia*+*i*+*k*:*ia*+*n*-1, *ja*+*i*-1), and *tau* in `tau`(`ja`+*i*-1).

The elements of the vectors *v* together form the (*n*-*k*+1)-by-*nb* matrix *V* which is needed, with *T* and *Y*, to apply the transformation to the unreduced part of the matrix, using an update of the form: `A(ia:ia+n-1`, *ja*:*ja*+*n*-*k*) := (*I*-*V***T***V'*)*(*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-*k*)-*Y***V'*). The contents of `A(ia:ia+n-1`, *ja*:*ja*+*n*-*k*) on exit are illustrated by the following example with `n = 7`, `k = 3`, and `nb = 2`:

$$\begin{bmatrix} a & h & a & a & a \\ a & h & a & a & a \\ a & h & a & a & a \\ h & h & a & a & a \\ v1 & h & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix}$$

where *a* denotes an element of the original matrix `A(ia:ia+n-1, ja:ja+n-k)`, *h* denotes a modified element of the upper Hessenberg matrix *H*, and *vi* denotes an element of the vector defining `H(i)`.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?laiect

Exploits IEEE arithmetic to accelerate the computations of eigenvalues. (C interface function).

Syntax

```
void pslaiect(float *sigma, int *n, float *d, int *count);
void pdlaiectb(float *sigma, int *n, float *d, int *count);
void pdlaiectl(float *sigma, int *n, float *d, int *count);
```

Description

The p?laiectroutine computes the number of negative eigenvalues of ($A - \sigma I$). This implementation of the Sturm Sequence loop exploits IEEE arithmetic and has no conditionals in the innermost loop. The signbit for real routine pslaiect is assumed to be bit 32. Double-precision routines pdlaiectb and pdlaiectl differ in the order of the double precision word storage and, consequently, in the signbit location. For pdlaiectb, the double precision word is stored in the big-endian word order and the signbit is assumed to be bit 32. For pdlaiectl, the double precision word is stored in the little-endian word order and the signbit is assumed to be bit 64.

Note that all arguments are call-by-reference so that this routine can be directly called from Fortran code.

This is a ScaLAPACK internal subroutine and arguments are not checked for unreasonable values.

Input Parameters

sigma

REALfor pslaiect

DOUBLE PRECISIONfor pdlaiectb/pdlaiectl.

The shift. p?laiect finds the number of eigenvalues less than equal to *sigma*.

n

INTEGER. The order of the tridiagonal matrix *T*. $n \geq 1$.

d

REALfor pslaiect

DOUBLE PRECISION for pdlaiectb/pdlaiectl.

Array of size $2n-1$.

On entry, this array contains the diagonals and the squares of the off-diagonal elements of the tridiagonal matrix *T*. These elements are assumed to be interleaved in memory for better cache performance. The diagonal entries of *T* are in the entries $d(1), d(3), \ldots, d(2n-1)$, while the squares of the off-diagonal entries are $d(2), d(4), \ldots, d(2n-2)$. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

Output Parameters

n

INTEGER. The count of the number of eigenvalues of *T* less than or equal to *sigma*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lamve

Copies all or part of one two-dimensional distributed array to another.

Syntax

```
call pslamve( uplo, m, n, a, ia, ja, desca, b, ib, jb, descb, dwork )
call pdlamve( uplo, m, n, a, ia, ja, desca, b, ib, jb, descb, dwork )
```

Description

`p?lamve` copies all or part of a distributed matrix *A* to another distributed matrix *B*. There is no alignment assumptions at all except that *A* and *B* are of the same size.

Input Parameters

uplo

(global) `CHARACTER*1`

Specifies the part of the distributed matrix sub(*A*) to be copied:

= 'U': Upper triangular part is copied; the strictly lower triangular part of sub(*A*) is not referenced;

= 'L': Lower triangular part is copied; the strictly upper triangular part of sub(*A*) is not referenced;

Otherwise: All of the matrix sub(*A*) is copied.

m

(global) `INTEGER`

The number of rows to be operated on, which is the number of rows of the distributed matrix sub(*A*). $m \geq 0$.

n

(global) `INTEGER`

The number of columns to be operated on, which is the number of columns of the distributed matrix sub(*A*). $n \geq 0$.

a

`REAL` for `pslamve`

`DOUBLE PRECISION` for `pdlamve`

(local) pointer into the local memory to an array of size (*lld_a*, $LOC_c(ja+n-1)$). This array contains the local pieces of the distributed matrix sub(*A*) to be copied from.

ia

(global) `INTEGER`

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja

(global) `INTEGER`

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca (global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *A*.

ib (global) INTEGER

The row index in the global matrix *B* indicating the first row of sub(*B*).

jb (global) INTEGER

The column index in the global matrix *B* indicating the first column of sub(*B*).

descb (global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *B*.

dwork REAL for pslamve

DOUBLE PRECISION for pdlamve

(local workspace) array

If *uplo* = 'U' or *uplo* = 'L' and number of processors > 1, the length of *dwork* is at least as large as the length of *b*.

Otherwise, *dwork* is not referenced.

OUTPUT Parameters

b REAL for pslamve

DOUBLE PRECISION for pdlamve

(local) pointer into the local memory to an array of size (*lld_b*, LOC_c(*jb* +*n*-1)). This array contains on exit the local pieces of the distributed matrix sub(*B*).

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.

Syntax

```
val = pslange(norm, m, n, a, ia, ja, desca, work)
val = pdlange(norm, m, n, a, ia, ja, desca, work)
val = pclange(norm, m, n, a, ia, ja, desca, work)
val = pzlange(norm, m, n, a, ia, ja, desca, work)
```

Description

The p?langeroutine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1).

Input Parameters

norm

(global) CHARACTER. Specifies what value is returned by the routine:

= 'M' or 'm': *val* = max(abs(A_{ij})), largest absolute value of the matrix *A*, it s not a matrix norm.

= '1' or 'O' or 'o': *val* = norm1(*A*), 1-norm of the matrix *A* (maximum column sum),

= 'I' or 'i': *val* = normI(*A*), infinity norm of the matrix *A* (maximum row sum),

= 'F', 'f', 'E' or 'e': *val* = normF(*A*), Frobenius norm of the matrix *A* (square root of sum of squares).

m

(global) INTEGER.

The number of rows in the distributed matrix sub(A). When *m* = 0, p?lange is set to zero. $m \geq 0$.

n

(global) INTEGER.

The number of columns in the distributed matrix sub(*A*). When *n* = 0, p?lange is set to zero. $n \geq 0$.

a

(local).

REAL for pslange

DOUBLE PRECISION for pdlange

COMPLEX for pclange

COMPLEX*16 for pzlange.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)) containing the local pieces of the distributed matrix sub(*A*).

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A.

work

(local).

REAL for pslange

DOUBLE PRECISION for pdlange

COMPLEX for pclange

COMPLEX*16 for pzlange.

Array size *lwork*.

lwork ≥ 0 if *norm* = 'M' or 'm' (not referenced),

*nq*0 if *norm* = '1', 'O' or 'o',

*mp*0 if *norm* = 'I' or 'i',

0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),

where

iroffa = mod(*ia*-1, *mb_a*), *icoffa* = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),

*mp*0 = numroc(*m*+*iroffa*, *mb_a*, *myrow*, *iarow*, *nprow*),

*nq*0 = numroc(*n*+*icoffa*, *nb_a*, *mycol*, *iacol*, *npcol*),

indxg2p and numroc are ScaLAPACK tool routines; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

val

REAL for pslange/pclange

DOUBLE PRECISION for pdlange/pzlange

The value returned by the routine.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lanhs

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.

Syntax

val = pslanhs(*norm*, *n*, *a*, *ia*, *ja*, *desca*, *work*)

val = pdlanhs(*norm*, *n*, *a*, *ia*, *ja*, *desca*, *work*)

val = pclanhs(*norm*, *n*, *a*, *ia*, *ja*, *desca*, *work*)

val = pzlanhs(*norm*, *n*, *a*, *ia*, *ja*, *desca*, *work*)

Description

The p?lanhsroutine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an upper Hessenberg distributed matrix sub(*A*) = *A*(*ia:ia+m-1*, *ja:ja+n-1*).

Input Parameters

norm

CHARACTER*1. Specifies the value to be returned by the routine:

= 'M' or 'm': *val* = max(abs(A_{ij})), largest absolute value of the matrix *A*.

= '1' or 'O' or 'o': *val* = norm1(*A*), 1-norm of the matrix *A* (maximum column sum),

= 'I' or 'i': *val* = normI(*A*), infinity norm of the matrix *A* (maximum row sum),

= 'F', 'f', 'E' or 'e': *val* = normF(*A*), Frobenius norm of the matrix *A* (square root of sum of squares).

n (global) INTEGER.

The number of columns in the distributed matrix sub(*A*). When *n* = 0, p?lanhs is set to zero. *n*≥ 0.

a (local).

REAL for pslanhs

DOUBLE PRECISION for pdlanhs

COMPLEX for pclanhs

COMPLEX*16 for pzlanhs.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)) containing the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER.

The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A.

work (local).

REAL for pslanhs

DOUBLE PRECISION for pdlanhs

COMPLEX for pclanhs

COMPLEX*16 for pzlanh.

Array of size *lwork*.

lwork ≥ 0 if *norm* = 'M' or 'm' (not referenced),

*nq*0 if *norm* = '1', 'O' or 'o',

*mp*0 if *norm* = 'I' or 'i',

0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),

where

iroffa = mod(*ia*-1, *mb_a*), *icoffa* = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),

*mp*0 = numroc(*m*+*iroffa*, *mb_a*, *myrow*, *iarow*, *nprow*),

*nq*0 = numroc(*n*+*icoffa*, *nb_a*, *mycol*, *iacol*, *npcol*),

indxg2p and numroc are ScaLAPACK tool routines; *myrow*, *imycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

val The value returned by the function.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lansy, p?lanhe

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a real symmetric or a complex Hermitian matrix.

Syntax

```
val = pslansy(norm, uplo, n, a, ia, ja, desca, work)
val = pdlansy(norm, uplo, n, a, ia, ja, desca, work)
val = pclansy(norm, uplo, n, a, ia, ja, desca, work)
val = pzlansy(norm, uplo, n, a, ia, ja, desca, work)
val = pclanhe(norm, uplo, n, a, ia, ja, desca, work)
val = pzlanhe(norm, uplo, n, a, ia, ja, desca, work)
```

Description

The p?lansy and p?lanheroutines return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1).

Input Parameters

norm

(global) CHARACTER. Specifies what value is returned by the routine:

= 'M' or 'm': *val* = max(abs(A_{ij})), largest absolute value of the matrix *A*, it s not a matrix norm.

= '1' or 'O' or 'o': *val* = norm1(*A*), 1-norm of the matrix *A* (maximum column sum),

= 'I' or 'i': *val* = normI(*A*), infinity norm of the matrix *A* (maximum row sum),

= 'F', 'f', 'E' or 'e': *val* = normF(*A*), Frobenius norm of the matrix *A* (square root of sum of squares).

uplo

(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric matrix sub(*A*) is to be referenced.

= 'U': Upper triangular part of sub(*A*) is referenced,

= 'L': Lower triangular part of sub(*A*) is referenced.

n

(global) INTEGER.

The number of columns in the distributed matrix sub(*A*). When *n* = 0, p?lansy is set to zero. $n \geq 0$.

a

(local).

REAL for pslansy

DOUBLE PRECISION for pdlansy

COMPLEX for pclansy, pclanhe

COMPLEX*16 for pzlansy, pzlanhe.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)) containing the local pieces of the distributed matrix sub(*A*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*A*) contains the upper triangular matrix whose norm is to be computed, and the strictly lower triangular part of this matrix is not referenced. If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular matrix whose norm is to be computed, and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

work

(local).

REAL for pslansy, pclansy, pclanhe

DOUBLE PRECISION for pdlansy, pzlansy, pzlanhe

Array of size *lwork*.

lwork ≥ 0 if *norm* = 'M' or 'm' (not referenced),

2**nq*0+*mp*0+*ldw* if *norm* = '1', 'O' or 'o', 'I' or 'i',

where *ldw* is given by:

```
if( nprow≠npcol ) then
ldw = mb_a*iceil(iceil(np0,mb_a),(lcm/nprow))
else
ldw = 0
end if
```

0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),

where *lcm* is the least common multiple of *nprow* and *npcol*, *lcm* = ilcm(*nprow*, *npcol*) and iceil(*x*,*y*) is a ScaLAPACK function that returns ceiling (*x*/*y*).

iroffa = mod(*ia*-1, *mb_a*), *icoffa* = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),

*mp*0 = numroc(*m*+*iroffa*, *mb_a*, *myrow*, *iarow*, *nprow*),

*nq*0 = numroc(*n*+*icoffa*, *nb_a*, *mycol*, *iacol*, *npcol*),

ilcm, iceil, indxg2p, and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

val

The value returned by the routine.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lantr

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.

Syntax

```
val = pslantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pdlantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pclantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pzlantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
```

Description

The p?lantrroutine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular distributed matrix sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1).

Input Parameters

norm

(global) CHARACTER. Specifies what value is returned by the routine:

= 'M' or 'm': *val* = max(abs(A_{ij})), largest absolute value of the matrix *A*, it s not a matrix norm.

= '1' or 'O' or 'o': *val* = norm1(*A*), 1-norm of the matrix *A* (maximum column sum),

= 'I' or 'i': *val* = normI(*A*), infinity norm of the matrix *A* (maximum row sum),

= 'F', 'f', 'E' or 'e': *val* = normF(*A*), Frobenius norm of the matrix *A* (square root of sum of squares).

uplo

(global) CHARACTER.

Specifies whether the upper or lower triangular part of the symmetric matrix sub(*A*) is to be referenced.

= 'U': Upper trapezoidal,

= 'L': Lower trapezoidal.

Note that sub(*A*) is triangular instead of trapezoidal if *m* = *n*.

diag

(global) CHARACTER.

Specifies whether the distributed matrix sub(*A*) has unit diagonal.

= 'N': Non-unit diagonal.

= 'U': Unit diagonal.

m

(global) INTEGER.

The number of rows in the distributed matrix sub(*A*). When *m* = 0, p?lantr is set to zero. *m* ≥ 0.

n (global) INTEGER.

The number of columns in the distributed matrix sub(*A*). When *n* = 0, p?lantr is set to zero. *n* ≥ 0.

a (local).

REAL for pslantr

DOUBLE PRECISION for pdlantr

COMPLEX for pclantr

COMPLEX*16 for pzlantr.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)) containing the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER.

The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A.

work (local).

REAL for pslantr

DOUBLE PRECISION for pdlantr

COMPLEX for pclantr

COMPLEX*16 for pzlantr.

Array size *lwork*.

lwork ≥ 0 if *norm* = 'M' or 'm' (not referenced),

*nq*0 if *norm* = '1', 'O' or 'o',

*mp*0 if *norm* = 'I' or 'i',

0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),

iroffa = mod(*ia*-1, *mb_a*), *icoffa* = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),

*mp*0 = numroc(*m*+*iroffa*, *mb_a*, *myrow*, *iarow*, *nprow*),

*nq*0 = numroc(*n*+*icoffa*, *nb_a*, *mycol*, *iacol*, *npcol*),

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

val The value returned by the routine.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lapiv

Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.

Syntax

```
call pslapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp, descip, iwork)
call pdlapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp, descip, iwork)
call pclapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp, descip, iwork)
call pzlapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp, descip, iwork)
```

Description

The p?lapivroutine applies either *P* (permutation matrix indicated by *ipiv*) or inv(*P*) to a general *m*-by-*n* distributed matrix sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1), resulting in row or column pivoting. The pivot vector may be distributed across a process row or a column. The pivot vector should be aligned with the distributed matrix *A*. This routine will transpose the pivot vector, if necessary.

For example, if the row pivots should be applied to the columns of sub(*A*), pass *rowcol*='C' and *pivroc*='C'.

Input Parameters

direc

(global) CHARACTER*1.

Specifies in which order the permutation is applied:

= 'F' (Forward): Applies pivots forward from top of matrix. Computes *P**sub(*A*).

= 'B' (Backward): Applies pivots backward from bottom of matrix. Computes inv(*P*)*sub(*A*).

rowcol

(global) CHARACTER*1.

Specifies if the rows or columns are to be permuted:

= 'R': Rows will be permuted,

= 'C': Columns will be permuted.

pivroc

(global) CHARACTER*1.

Specifies whether *ipiv* is distributed over a process row or column:

= 'R': *ipiv* is distributed over a process row,

= 'C': *ipiv* is distributed over a process column.

m

(global) INTEGER.

The number of rows in the distributed matrix sub(*A*). When *m* = 0, p?lapiv is set to zero. *m* ≥ 0.

n

(global) INTEGER.

The number of columns in the distributed matrix sub(*A*). When *n* = 0, p?lapiv is set to zero. *n* ≥ 0.

a

(local).

REAL for pslapiv

DOUBLE PRECISION for pdlapiv

COMPLEX for pclapiv

COMPLEX*16 for pzlapiv.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)) containing the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER.

The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A.

ipiv (local) INTEGER.

Array of size *lipiv* ;

when *rowcol*='R' or 'r':

lipiv≥*LOCr*(*ia*+*m*-1) + *mb_a* if *pivroc*='C' or 'c',

lipiv≥*LOCc*(*m* + *mod*(*jp*-1, *nb_p*)) if *pivroc*='R' or 'r', and,

when *rowcol*='C' or 'c':

lipiv≥*LOCr*(*n* + mod(*ip*-1, *mb_p*)) if *pivroc*='C' or 'c',

lipiv≥*LOCc*(*ja*+*n*-1) + *nb_a* if *pivroc*='R' or 'r'.

This array contains the pivoting information. *ipiv(i)* is the global row (column), local row (column) *i* was swapped with. When *rowcol*='R' or 'r' and *pivroc*='C' or 'c', or *rowcol*='C' or 'c' and *pivroc*='R' or 'r', the last piece of this array of size *mb_a* (resp. *nb_a*) is used as workspace. In those cases, this array is tied to the distributed matrix *A*.

ip, *jp* (global) INTEGER. The row and column indices in the global matrix *P* indicating the first row and the first column of the matrix sub(*P*), respectively.

descip (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed vector *ipiv*.

iwork (local). INTEGER.

Array of size *ldw*, where *ldw* is equal to the workspace necessary for transposition, and the storage of the transposed *ipiv*:

Let *lcm* be the least common multiple of *nprow* and *npcol*.

```
if( rowcol.eq.'r' .and.  pivroc. eq.'r') then
      if( nprow.eq. npcol) then
ldw = LOCr( n_p + mod(jp-1, nb_p) ) + nb_p
     else
ldw = LOCr( n_p + mod(jp-1, nb_p) )+
nb_p * ceil( ceil(LOCc(n_p)/nb_p) / (lcm/npcol) )
   end if
 else if( rowcol.eq.'c' .and.  pivroc.eq.'c') then
```

```
       if( nprow.eq. npcol ) then
ldw = LOCc( m_p + mod(ip-1, mb_p) ) + mb_p
       else
ldw = LOCc( m_p + mod(ip-1, mb_p) ) +
mb_p *ceil(ceil(LOCr(m_p)/mb_p) / (lcm/nprow) )
       end if
 else
iwork is not referenced.
 end if
```

Output Parameters

a (local).

On exit, the local pieces of the permuted distributed submatrix.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lapv2

Applies a permutation to an m-by-n distributed matrix.

Syntax

```
call pslapv2 (direc, rowcol, m, n, a, ia, ja, desca, ipiv, ip, jp, descip )
call pdlapv2 (direc, rowcol, m, n, a, ia, ja, desca, ipiv, ip, jp, descip )
call pclapv2 (direc, rowcol, m, n, a, ia, ja, desca, ipiv, ip, jp, descip )
call pzlapv2 (direc, rowcol, m, n, a, ia, ja, desca, ipiv, ip, jp, descip )
```

Description

p?lapv2 applies either *P* (permutation matrix indicated by *ipiv*) or inv(*P*) to an *m*-by-*n* distributed matrix sub(*A*) denoting *A*(*ia*:*ia*+*m*-1,*ja*:*ja*+*n*-1), resulting in row or column pivoting. The pivot vector should be aligned with the distributed matrix *A*. For pivoting the rows of sub(*A*), *ipiv* should be distributed along a process column and replicated over all process rows. Similarly, *ipiv* should be distributed along a process row and replicated over all process columns for column pivoting.

Input Parameters

direc (global)

CHARACTER.

Specifies in which order the permutation is applied:

= 'F' (Forward) Applies pivots Forward from top of matrix. Computes *P* * sub(*A*);

= 'B' (Backward) Applies pivots Backward from bottom of matrix. Computes inv(*P*) * sub(*A*).

rowcol (global)

CHARACTER.

Specifies if the rows or columns are to be permuted:

= 'R' Rows will be permuted,

= 'C' Columns will be permuted.

m (global)

INTEGER.

The number of rows to be operated on, i.e. the number of rows of the distributed submatrix sub(*A*). *m* >= 0.

n (global)

INTEGER.

The number of columns to be operated on, i.e. the number of columns of the distributed submatrix sub(*A*). *n* >= 0.

a Pointer into local memory to an array of size (*lld_a*,*LOCc*(*ja*+*n*-1)) .

On entry, this local array contains the local pieces of the distributed matrix sub(*A*) to which the row or columns interchanges will be applied.

ia (global)

INTEGER.

The row index in the global array *a* indicating the first row of sub(*A*).

ja (global)

INTEGER.

The column index in the global array *a* indicating the first column of sub(*A*).

desca (global and local)

INTEGER.

Array of size *dlen_*.

The array descriptor for the distributed matrix *A*.

ipiv INTEGER.

Array, size >= LOCr(*m_a*)+*mb_a* if *rowcol* = 'R', LOCc(*n_a*)+*nb_a* otherwise.

It contains the pivoting information. *ipiv*(*i*) is the global row (column), local row (column) *i* was swapped with. The last piece of the array of size *mb_a* or *nb_a* is used as workspace. *ipiv* is tied to the distributed matrix *A*.

ip (global)

INTEGER.

The global row index of *ipiv*, which points to the beginning of the submatrix on which to operate.

jp (global)

INTEGER.

The global column index of *ipiv*, which points to the beginning of the submatrix on which to operate.

descip (global and local)

INTEGER.

Array of size 8.

The array descriptor for the distributed matrix *ipiv*.

Output Parameters

a — On exit, this array contains the local pieces of the permuted distributed matrix.

p?laqge

Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ .

Syntax

```
call pslaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
call pdlaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
call pclaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
call pzlaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
```

Description

The p?laqgeroutine equilibrates a general *m*-by-*n* distributed matrix sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1) using the row and scaling factors in the vectors *r* and *c* computed by p?geequ.

Input Parameters

m — (global) INTEGER.

The number of rows in the distributed matrix sub(*A*). (*m* ≥0).

n — (global) INTEGER.

The number of columns in the distributed matrix sub(*A*). (*n* ≥0).

a — (local).

REAL for pslaqge

DOUBLE PRECISION for pdlaqge

COMPLEX for pclaqge

COMPLEX*16 for pzlaqge.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)).

On entry, this array contains the distributed matrix sub(*A*).

ia, *ja* — (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.

desca — (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

r — (local).

REAL for pslaqge

DOUBLE PRECISION for pdlaqge

COMPLEX for pclaqge

COMPLEX*16 for pzlaqge.

Array of size *LOCr(m_a)*. The row scale factors for sub(*A*). *r* is aligned with the distributed matrix *A*, and replicated across every process column. *r* is tied to the distributed matrix *A*.

c (local).

REAL for pslaqge

DOUBLE PRECISION for pdlaqge

COMPLEX for pclaqge

COMPLEX*16 for pzlaqge.

Array of size *LOCc(n_a)*. The row scale factors for sub(*A*). *c* is aligned with the distributed matrix *A*, and replicated across every process column. *c* is tied to the distributed matrix *A*.

rowcnd (local).

REAL for pslaqge

DOUBLE PRECISION for pdlaqge

COMPLEX for pclaqge

COMPLEX*16 for pzlaqge.

The global ratio of the smallest *r(i)* to the largest *r(i)*, $ia \le i \le ia+m-1$.

colcnd (local).

REAL for pslaqge

DOUBLE PRECISION for pdlaqge

COMPLEX for pclaqge

COMPLEX*16 for pzlaqge.

The global ratio of the smallest *c(i)* to the largest *c(i)*, $ia \le i \le ia+n-1$.

amax (global). REAL for pslaqge

DOUBLE PRECISION for pdlaqge

COMPLEX for pclaqge

COMPLEX*16 for pzlaqge.

Absolute value of largest distributed submatrix entry.

Output Parameters

a (local).

On exit, the equilibrated distributed matrix. See *equed* for the form of the equilibrated distributed submatrix.

equed (global) CHARACTER.

Specifies the form of equilibration that was done.

= 'N': No equilibration

= 'R': Row equilibration, that is, sub(*A*) has been pre-multiplied by diag(r(ia:ia+m-1)),

= 'C': column equilibration, that is, sub(*A*) has been post-multiplied by diag(c(ja:ja+n-1)),

= 'B': Both row and column equilibration, that is, sub(*A*) has been replaced by diag(r(ia:ia+m-1))* sub(*A*) * diag(c(ja:ja+n-1)).

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?laqr0

Computes the eigenvalues of a Hessenberg matrix and optionally returns the matrices from the Schur decomposition.

Syntax

call pslaqr0(*wantt*, *wantz*, *n*, *ilo*, *ihi*, *h*, *desch*, *wr*, *wi*, *iloz*, *ihiz*, *z*, *descz*, *work*, *lwork*, *iwork*, *liwork*, *info*, *reclevel*)

call pdlaqr0(*wantt*, *wantz*, *n*, *ilo*, *ihi*, *h*, *desch*, *wr*, *wi*, *iloz*, *ihiz*, *z*, *descz*, *work*, *lwork*, *iwork*, *liwork*, *info*, *reclevel*)

Description

p?laqr0 computes the eigenvalues of a Hessenberg matrix *H* and, optionally, the matrices T and *Z* from the Schur decomposition $H = Z*T*Z^T$, where *T* is an upper quasi-triangular matrix (the Schur form), and *Z* is the orthogonal matrix of Schur vectors.

Optionally *Z* may be postmultiplied into an input orthogonal matrix *Q* so that this routine can give the Schur factorization of a matrix *A* which has been reduced to the Hessenberg form *H* by the orthogonal matrix *Q*: $A = Q * H * Q^T = (QZ) * T * (QZ)^T$.

Input Parameters

wantt (global) LOGICAL

= .TRUE. : the full Schur form *T* is required;

= .FALSE. : only eigenvalues are required.

wantz (global) LOGICAL

= .TRUE. : the matrix of Schur vectors *Z* is required;

= .FALSE.: Schur vectors are not required.

n (global) INTEGER

The order of the Hessenberg matrix *H* (and *Z* if *wantz*). $n \geq 0$.

ilo, *ihi* (global) INTEGER

It is assumed that the matrix *H* is already upper triangular in rows and columns 1:*ilo*-1 and *ihi*+1:*n*. *ilo* and *ihi* are normally set by a previous call to p?gebal, and then passed to p?gehrd when the matrix output by *ihi* is reduced to Hessenberg form. Otherwise *ilo* and *ihi* should be set to 1 and *n*, respectively. If $n > 0$, then $1 \le ilo \le ihi \le n$.

If $n = 0$, then $ilo = 1$ and $ihi = 0$.

h

REAL for pslaqr0

DOUBLE PRECISION for pdlaqr0

(global) array of size (*lld_h*, $LOC_c(n)$)

The upper Hessenberg matrix *H*.

desch

(global and local) INTEGER

Array of size *dlen_*.

The array descriptor for the distributed matrix *H*.

iloz, *ihiz*

INTEGER

Specify the rows of the matrix *Z* to which transformations must be applied if *wantz* is .TRUE., $1 \le iloz \le ilo$; $ihi \le ihiz \le n$.

z

REAL for pslaqr0

DOUBLE PRECISION for pdlaqr0

Array of size (*lld_z*, $LOC_c(n)$).

If *wantz* is .TRUE., contains the matrix *Z*.

If *wantz*is .FALSE., *z* is not referenced.

descz

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *Z*.

work

REAL for pslaqr0

DOUBLE PRECISION for pdlaqr0

(local workspace) array of size *lwork*

lwork

(local) INTEGER

The length of the workspace array *work*.

iwork

(local workspace) INTEGER array of size *liwork*

liwork

(local) INTEGER

The length of the workspace array *iwork*.

reclevel

(local) INTEGER

Level of recursion. *reclevel* = 0 must hold on entry.

OUTPUT Parameters

h

On exit, if *wantt* is .TRUE., the matrix *H* is upper quasi-triangular in rows and columns *ilo*:*ihi*, with 1-by-1 and 2-by-2 blocks on the main diagonal. The 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with *H*(*i*,*i*) = *H*(*i*+1,*i*+1) and *H*(*i*+1,*i*)**H*(*i*,*i*+1) < 0. If *info* = 0 and *wantt*is .FALSE., the contents of *h* are unspecified on exit.

wr, *wi*

REAL for pslaqr0

DOUBLE PRECISION for pdlaqr0

The real and imaginary parts, respectively, of the computed eigenvalues *ilo* to *ihi* are stored in the corresponding elements of *wr* and *wi*. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and (*i*+1)th, with *wi*(*i*) > 0 and *wi*(*i*+1) < 0. If *wantt* is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*.

z

Updated matrix with transformations applied only to the submatrix *Z*(*ilo*:*ihi*,*ilo*:*ihi*).

If COMPZ = 'I', on exit, if *info* = 0, *z* contains the orthogonal matrix *Z* of the Schur vectors of *H*.

If *wantz* is .TRUE., then *Z*(*ilo*:*ihi*,*iloz*:*ihi*z) is replaced by *Z*(*ilo*:*ihi*,*iloz*:*ihiz*)**U*, when *U* is the orthogonal/unitary Schur factor of *H*(*ilo*:*ihi*,*ilo*:*ihi*).

If *wantz*is .FALSE., then *z* is not defined.

work(1)

On exit, if *info* = 0, *work*(1) returns the optimal *lwork*.

iwork(1)

On exit, if *info* = 0, *iwork*(1) returns the optimal *liwork*.

info

INTEGER

> 0: if *info* = *i*, then the routine failed to compute all the eigenvalues. Elements 1:*ilo*-1 and *i*+1:*n* of *wr* and *wi* contain those eigenvalues which have been successfully computed.

> 0: if *wantt*is .FALSE., then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns *ilo* through *ihi* of the final output value of *h*.

> 0: if *wantt* is .TRUE., then (initial value of *H*)**U* = *U**(final value of *H*), where *U* is an orthogonal/unitary matrix. The final value of *H* is upper Hessenberg and quasi-triangular/triangular in rows and columns *info*+1 through *ihi*.

> 0: if *wantz* is .TRUE., then (final value of *Z*(*ilo*:*ihi*,*iloz*:*ihiz*))=(initial value of *Z*(*ilo*:*ihi*,*iloz*:*ihiz*))**U*, where *U* is the orthogonal/unitary matrix in the previous expression (regardless of the value of *wantt*).

> 0: if *wantz*is .FALSE., then *z* is not accessed.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?laqr1

Sets a scalar multiple of the first column of the product of a 2-by-2 or 3-by-3 matrix and specified shifts.

Syntax

```
call pslaqr1( wantt, wantz, n, ilo, ihi, a, desca, wr, wi, iloz, ihiz, z, descz, work, lwork, iwork, ilwork, info )
```

```
call pdlaqr1( wantt, wantz, n, ilo, ihi, a, desca, wr, wi, iloz, ihiz, z, descz, work, lwork, iwork, ilwork, info )
```

Description

`p?laqr1` is an auxiliary routine used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns *ilo* to *ihi*.

This is a modified version of `p?lahqr` from ScaLAPACK version 1.7.3. The following modifications were made:

- Workspace query functionality was added.
- Aggressive early deflation is implemented.
- Aggressive deflation (looking for two consecutive small subdiagonal elements by PSLACONSB) is abandoned.
- The returned Schur form is now in canonical form, i.e., the returned 2-by-2 blocks really correspond to complex conjugate pairs of eigenvalues.
- For some reason, the original version of `p?lahqr` sometimes did not read out the converged eigenvalues correctly. This is now fixed.

Input Parameters

wantt (global) `LOGICAL`

= `.TRUE.` : the full Schur form *T* is required;

= `.FALSE.`: only eigenvalues are required.

wantz (global) LOGICAL

= `.TRUE.` : the matrix of Schur vectors *Z* is required;

= `.FALSE.`: Schur vectors are not required.

n (global) `LOGICAL`

The order of the Hessenberg matrix *A* (and *Z* if *wantz*). $n \geq 0$.

ilo, *ihi* (global) `INTEGER`

It is assumed that the matrix *A* is already upper quasi-triangular in rows and columns *ihi*+1:*n*, and that A(*ilo*,*ilo*-1) = 0 (unless *ilo* = 1). p?laqr1 works primarily with the Hessenberg submatrix in rows and columns *ilo* to *ihi*, but applies transformations to all of *H* if *wantt* is .TRUE..

1 ≤*ilo*≤ max(1,*ihi*); *ihi*≤*n*.

a

REAL for pslaqr1

DOUBLE PRECISION for pdlaqr1

(global) array of size (*lld_a*,LOC_c(*n*))

On entry, the upper Hessenberg matrix *A*.

desca

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *A*.

iloz, *ihiz*

(global) INTEGER

Specify the rows of the matrix *Z* to which transformations must be applied if *wantz* is .TRUE..

1 ≤*iloz*≤*ilo*; *ihi*≤*ihiz*≤*n*.

z

REAL for pslaqr1

DOUBLE PRECISION for pdlaqr1

(global) array of size (*lld_z*,LOC_c(*n*)).

If *wantz* is .TRUE., on entry *z* must contain the current matrix *Z* of transformations accumulated by p?hseqr

If *wantz* is .FALSE., *z* is not referenced.

descz

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *Z*.

work

REAL for pslaqr1

DOUBLE PRECISION for pdlaqr1

(local output) array of size *lwork*

lwork

(local) INTEGER

The size of the work array (*lwork*>=1).

If *lwork*=-1, then a workspace query is assumed.

iwork

(global and local) INTEGER array of size *ilwork*

This holds the some of the IBLK integer arrays.

ilwork

(local) INTEGER

The size of the *iwork* array (*ilwork*≥ 3).

OUTPUT Parameters

a	If *wantt* is .TRUE., the matrix *A* is upper quasi-triangular in rows and columns *ilo*:*ihi*, with any 2-by-2 or larger diagonal blocks not yet in standard form. If *wantt*is .FALSE., the contents of *a* are unspecified on exit.
wr, *wi*	REAL for pslaqr1 DOUBLE PRECISION for pdlaqr1 (global replicated) array of size *n* The real and imaginary parts, respectively, of the computed eigenvalues *ilo* to *ihi* are stored in the corresponding elements of *wr* and *wi*. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and (*i*+1)th, with *wi*(*i*) > 0 and *wi*(*i*+1) < 0. If *wantt* is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *a*. *a* may be returned with larger diagonal blocks until the next release.
z	On exit *z* is updated; transformations are applied only to the submatrix *Z*(*iloz*:*ihiz*,*ilo*:*ihi*). If *wantz*is .FALSE., *z* is not referenced.
work(1)	On exit, if *info* = 0, *work*(1) returns the optimal *lwork*.
info	(global) INTEGER < 0: parameter number -*info* incorrect or inconsistent = 0: successful exit > 0: p?laqr1 failed to compute all the eigenvalues *ilo* to *ihi* in a total of 30*(*ihi*-*ilo*+1) iterations; if *info* = *i*, elements *i*+1:*ihi* of *wr* and *wi* contain those eigenvalues which have been successfully computed.

Application Notes

This algorithm is very similar to p?ahqr. Unlike p?lahqr, instead of sending one double shift through the largest unreduced submatrix, this algorithm sends multiple double shifts and spaces them apart so that there can be parallelism across several processor row/columns. Another critical difference is that this algorithm aggregrates multiple transforms together in order to apply them in a block fashion.

Current Notes and/or Restrictions:

- This code requires the distributed block size to be square and at least six (6); unlike simpler codes like LU, this algorithm is extremely sensitive to block size. Unwise choices of too small a block size can lead to bad performance.
- This code requires *a* and *z* to be distributed identically and have identical contxts.
- This release currently does not have a routine for resolving the Schur blocks into regular 2x2 form after this code is completed. Because of this, a significant performance impact is required while the deflation is done by sometimes a single column of processors.
- This code does not currently block the initial transforms so that none of the rows or columns for any bulge are completed until all are started. To offset pipeline start-up it is recommended that at least 2*LCM(NPROW,NPCOL) bulges are used (if possible)
- The maximum number of bulges currently supported is fixed at 32. In future versions this will be limited only by the incoming *work* array.

- The matrix *A* must be in upper Hessenberg form. If elements below the subdiagonal are nonzero, the resulting transforms may be nonsimilar. This is also true with the LAPACK routine.
- For this release, it is assumed *rsrc_*=*csrc_*=0
- Currently, all the eigenvalues are distributed to all the nodes. Future releases will probably distribute the eigenvalues by the column partitioning.
- The internals of this routine are subject to change.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?laqr2

Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax

```
call pslaqr2( wantt, wantz, n, ktop, kbot, nw, a, desca, iloz, ihiz, z, descz, ns, nd,
sr, si, t, ldt, v, ldv, wr, wi, work, lwork )
```

```
call pdlaqr2( wantt, wantz, n, ktop, kbot, nw, a, desca, iloz, ihiz, z, descz, ns, nd,
sr, si, t, ldt, v, ldv, wr, wi, work, lwork )
```

Description

`p?laqr2` accepts as input an upper Hessenberg matrix *A* and performs an orthogonal similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output *A*is overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal similarity transformation of *A*. It is to be hoped that the final version of *A* has many zero subdiagonal entries.

This routine handles small deflation windows which is affordable by one processor. Normally, it is called by `p?laqr1`. All the inputs are assumed to be valid without checking.

Input Parameters

wantt

(global) `LOGICAL`

If `.TRUE.`, then the Hessenberg matrix *A* is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling subroutine).

If `.FALSE.`, then only enough of *A* is updated to preserve the eigenvalues.

wantz

(global) `LOGICAL`

If `.TRUE.`, then the orthogonal matrix *Z* is updated so that the orthogonal Schur factor may be computed (in cooperation with the calling subroutine).

If `.FALSE.`, then *z* is not referenced.

n

(global) `INTEGER`

The order of the matrix *A* and (if *wantz* is .TRUE.) the order of the orthogonal matrix *Z*.

ktop, *kbot*

(global) INTEGER

It is assumed without a check that either *kbot* = *n* or *A*(*kbot*+1,*kbot*)=0. *kbot* and *ktop* together determine an isolated block along the diagonal of the Hessenberg matrix. However, *A*(*ktop*,*ktop*-1)=0 is not essentially necessary if *wantt* is .TRUE. .

nw

(global) INTEGER

Deflation window size. 1 ≤*nw*≤ (*kbot*-*ktop*+1). Normally *nw*≥ 3 if p?laqr2 is called by p?laqr1.

a

REAL for pslaqr2

DOUBLE PRECISION for pdlaqr2

(local) array of size (*lld_a*,LOC_c(*n*))

The initial *n*-by-*n* section of *a* stores the Hessenberg matrix undergoing aggressive early deflation.

desca

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *A*.

iloz, *ihiz*

(global) INTEGER

Specify the rows of *z* to which transformations must be applied if *wantz* is .TRUE.. 1 ≤*iloz*≤*ihiz*≤*n*.

z

REAL for pslaqr2

DOUBLE PRECISION for pdlaqr2

Array of size (*lld_z*,LOC_c(*n*))

If *wantz* is .TRUE., then on output, the orthogonal similarity transformation mentioned above has been accumulated into *z*(*iloz*:*ihiz*, *kbot*:*ktop*) from the right.

If *wantz* is .FALSE., then *z* is unreferenced.

descz

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *Z*.

t

REAL for pslaqr2

DOUBLE PRECISION for pdlaqr2

(local workspace) array of size *ldt***nw*.

ldt

(local) INTEGER

The leading dimension of the array *t*. *ldt*≥*nw*.

v

REAL for pslaqr2

DOUBLE PRECISION for pdlaqr2

(local workspace) array of size *ldv***nw*.

ldv (local) INTEGER

The leading dimension of the array *v*. *ldv*≥*nw*.

wr, *wi* REAL for pslaqr2

DOUBLE PRECISION for pdlaqr2

(local workspace) array of size *kbot*.

work REAL for pslaqr2

DOUBLE PRECISION for pdlaqr2

(local workspace) array of size *lwork*.

lwork (local) INTEGER

work(*lwork*) is a local array and *lwork* is assumed big enough so that *lwork*≥*nw***nw*.

OUTPUT Parameters

a On output *a* has been transformed by an orthogonal similarity transformation, perturbed, and returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

z

ns (global) INTEGER

The number of unconverged (that is, approximate) eigenvalues returned in *sr* and *si* that may be used as shifts by the calling subroutine.

nd (global) INTEGER

The number of converged eigenvalues uncovered by this subroutine.

sr, *si* REAL for pslaqr2

DOUBLE PRECISION for pdlaqr2

(global) array of size *kbot*

On output, the real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in *sr*(*kbot*-*nd*-*ns*+1) through *sr*(*kbot*-*nd*) and *si*(*kbot*-*nd*-*ns*+1) through *si*(*kbot*-*nd*), respectively.

On processor #0, the real and imaginary parts of converged eigenvalues are stored in *sr*(*kbot*-*nd*+1) through *sr*(*kbot*) and *si*(*kbot*-*nd*+1) through *si*(*kbot*), respectively. On other processors, these entries are set to zero.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?laqr3

Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax

call pslaqr3(*wantt*, *wantz*, *n*, *ktop*, *kbot*, *nw*, *h*, *desch*, *iloz*, *ihiz*, *z*, *descz*, *ns*, *nd*, *sr*, *si*, *v*, *descv*, *nh*, *t*, *desct*, *nv*, *wv*, *descw*, *work*, *lwork*, *iwork*, *liwork*, *reclevel*)

call pdlaqr3(*wantt*, *wantz*, *n*, *ktop*, *kbot*, *nw*, *h*, *desch*, *iloz*, *ihiz*, *z*, *descz*, *ns*, *nd*, *sr*, *si*, *v*, *descv*, *nh*, *t*, *desct*, *nv*, *wv*, *descw*, *work*, *lwork*, *iwork*, *liwork*, *reclevel*)

Description

This subroutine accepts as input an upper Hessenberg matrix *H* and performs an orthogonal similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output *H* is overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal similarity transformation of *H*. It is to be hoped that the final version of *H* has many zero subdiagonal entries.

Input Parameters

wantt

(global) LOGICAL

If .TRUE., then the Hessenberg matrix *H* is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling subroutine).

If .FALSE., then only enough of *H* is updated to preserve the eigenvalues.

wantz

(global) LOGICAL

If .TRUE., then the orthogonal matrix *Z* is updated so that the orthogonal Schur factor may be computed (in cooperation with the calling subroutine).

If .FALSE., then *z* is not referenced.

n

(global) INTEGER

The order of the matrix *H* and (if *wantz* is .TRUE.), the order of the orthogonal matrix *Z*.

ktop

(global) INTEGER

It is assumed that either *ktop* = 1 or *H* (*ktop*,*ktop*-1)=0. *kbot* and *ktop* together determine an isolated block along the diagonal of the Hessenberg matrix.

kbot

(global) INTEGER

It is assumed without a check that either *kbot* = *n* or *H* (*kbot*+1,*kbot*)=0. *kbot* and *ktop* together determine an isolated block along the diagonal of the Hessenberg matrix.

nw

(global) INTEGER

Deflation window size. 1 ≤*nw*≤ (*kbot*-*ktop*+1).

h

REAL for pslaqr3

DOUBLE PRECISION for pdlaqr3

(local) array of size (*lld_h*,$LOC_c(n)$)

The initial *n*-by-*n* section of *H* stores the Hessenberg matrix undergoing aggressive early deflation.

desch

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *H*.

iloz, *ihiz* (global) INTEGER

Specify the rows of the matrix *Z* to which transformations must be applied if *wantz* is .TRUE.. 1 ≤*iloz*≤*ihiz*≤*n*.

z REAL for pslaqr3

DOUBLE PRECISION for pdlaqr3

Array of size (*lld_z*,LOC_c(*n*))

If *wantz* is .TRUE., then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix *Z*(*iloz*:*ihiz*,*kbot*:*ktop*) from the right.

If *wantz* is .FALSE., then *z* is unreferenced.

descz (global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *Z*.

v REAL for pslaqr3

DOUBLE PRECISION for pdlaqr3

(global workspace) array of size (*lld_v*,LOC_c(*nw*))

An *nw*-by-*nw* distributed work array.

descv (global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *V*.

nh INTEGER scalar

The number of columns of *t*. *nh*≥*nw*.

t REAL for pslaqr3

DOUBLE PRECISION for pdlaqr3

(global workspace) array of size (*lld_t*,LOC_c(*nh*))

desct (global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *T*.

nv (global) INTEGER

The number of rows of work array *wv* available for workspace. *nv*≥*nw*.

wv (global workspace) REAL array of size (*lld_w*,LOC_c(*nw*))

descw (global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *wv*.

work (local workspace) REAL array of size *lwork*.

lwork (local) INTEGER

The size of the work array *work* (*lwork*≥1). *lwork* = 2**nw* suffices, but greater efficiency may result from larger values of *lwork*.

If *lwork* = -1, then a workspace query is assumed; p?laqr3 only estimates the optimal workspace size for the given values of *n*, *nw*, *ktop* and *kbot*. The estimate is returned in *work*(1). No error message related to *lwork* is issued by xerbla. Neither *h* nor *z* are accessed.

iwork (local workspace) INTEGER array of size *liwork*

liwork (local) INTEGER

The length of the workspace array *iwork* (*liwork*≥1).

If *liwork*=-1, then a workspace query is assumed.

OUTPUT Parameters

h On output *h* has been transformed by an orthogonal similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

z IF *wantz* is .TRUE., then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix *Z*(*iloz*:*ihiz*,*kbot*:*ktop*) from the right.

If *wantz* is .FALSE., then *z* is unreferenced.

ns (global) INTEGER

The number of unconverged (that is, approximate) eigenvalues returned in *sr* and *si* that may be used as shifts by the calling subroutine.

nd (global) INTEGER

The number of converged eigenvalues uncovered by this subroutine.

sr, *si* REAL for pslaqr3

DOUBLE PRECISION for pdlaqr3

(global) array of size *kbot*. The real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in *sr*(*kbot*-*nd*-*ns*+1) through *sr*(*kbot*-*nd*) and *si*(*kbot*-*nd*-*ns*+1) through *si*(*kbot*-*nd*), respectively. The real and imaginary parts of converged eigenvalues are stored in *sr*(*kbot*-*nd*+1) through *sr*(*kbot*) and *si*(*kbot*-*nd*+1) through *si*(*kbot*), respectively.

work(1) On exit, if *info* = 0, *work*(1) returns the optimal *lwork*

iwork(1) On exit, if *info* = 0, *iwork*(1) returns the optimal *liwork*

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?laqr4

Computes the eigenvalues of a Hessenberg matrix, and optionally computes the matrices from the Schur decomposition.

Syntax

call pslaqr4(*wantt*, *wantz*, *n*, *ilo*, *ihi*, *a*, *desca*, *wr*, *wi*, *iloz*, *ihiz*, *z*, *descz*, *t*, *ldt*, *v*, *ldv*, *work*, *lwork*, *info*)

call pdlaqr4(*wantt*, *wantz*, *n*, *ilo*, *ihi*, *a*, *desca*, *wr*, *wi*, *iloz*, *ihiz*, *z*, *descz*, *t*, *ldt*, *v*, *ldv*, *work*, *lwork*, *info*)

Description

p?laqr4 is an auxiliary routine used to find the Schur decomposition and or eigenvalues of a matrix already in Hessenberg form from cols *ilo* to *ihi*. This routine requires that the active block is small enough, i.e. *ihi*-*ilo*+1 ≤*ldt*, so that it can be solved by LAPACK. Normally, it is called by p?laqr1. All the inputs are assumed to be valid without checking.

Input Parameters

wantt

(global) LOGICAL

= .TRUE.: the full Schur form *T* is required;

= .FALSE.: only eigenvalues are required.

wantz

(global) LOGICAL

= .TRUE.: the matrix of Schur vectors *Z* is required;

= .FALSE.: Schur vectors are not required.

n

(global) INTEGER

The order of the Hessenberg matrix *A* (and *Z* if *wantz*). *n*≥ 0.

ilo, *ihi*

(global) INTEGER

It is assumed that *a* is already upper quasi-triangular in rows and columns *ihi*+1:*n*, and that *A*(*ilo*,*ilo*-1) = 0 (unless *ilo* = 1). p?laqr4 works primarily with the Hessenberg submatrix in rows and columns *ilo* to *ihi*, but applies transformations to all of *A* if *wantt* is .TRUE.. 1 ≤*ilo*≤ max(1,*ihi*); *ihi*≤*n*.

a

REAL for pslaqr4

DOUBLE PRECISION for pdlaqr4

(global) array of size (*lld_a*,$LOC_c(n)$)

The upper Hessenberg matrix *A*.

desca

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *a*.

iloz, *ihiz*

(global) INTEGER

Specify the rows of the matrix *Z* to which transformations must be applied if *wantz* is .TRUE.. 1 ≤*iloz*≤*ilo*; *ihi*≤*ihiz*≤*n*.

z

REAL for pslaqr4

DOUBLE PRECISION for pdlaqr4

(global) array.

If *wantz* is .TRUE., on entry *z* must contain the current matrix *Z* of transformations accumulated by p?hseqr.

If *wantz* is .FALSE., *z* is not referenced.

descz (global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *Z*.

t REAL for pslaqr4

DOUBLE PRECISION for pdlaqr4

(local workspace) array of size *ldt**(*ihi*-*ilo*+1).

ldt (local) INTEGER

The leading dimension of the array *t*. *ldt*≥*ihi*-*ilo*+1.

v REAL for pslaqr4

DOUBLE PRECISION for pdlaqr4

(local workspace) array of size *ldv**(*ihi*-*ilo*+1).

ldv (local) INTEGER

The leading dimension of the array *v*. *ldv*≥*ihi*-*ilo*+1.

work REAL for pslaqr4

DOUBLE PRECISION for pdlaqr4

(local workspace) array of size *lwork*.

lwork (local) INTEGER

The size of the work array *work*.

lwork≥*ihi*-*ilo*+1.

OUTPUT Parameters

a On exit, if *wantt* is .TRUE., the matrix *A* is upper quasi-triangular in rows and columns *ilo*:*ihi*, with any 2-by-2 or larger diagonal blocks not yet in standard form. If *wantt*is .FALSE., the contents of *a* are unspecified on exit.

wr, *wi* REAL for pslaqr4

DOUBLE PRECISION for pdlaqr4

(global replicated) array of size *n*

The real and imaginary parts, respectively, of the computed eigenvalues *ilo* to *ihi* are stored in the corresponding elements of *wr* and *wi*. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and (*i*+1)th, with *wi*(*i*) > 0 and *wi*(*i*+1) < 0. If *wantt* is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *a*. The matrix *A* may be returned with larger diagonal blocks until the next release.

z If *wantz* is .TRUE., *z* is updated with transformations applied only to the submatrix *Z*(*iloz*:*ihiz*,*ilo*:*ihi*).

info (global) INTEGER

< 0: parameter number -*info* incorrect or inconsistent;

= 0: successful exit;

p?laqr5

Performs a single small-bulge multi-shift QR sweep.

Syntax

```
call pslaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, desch, iloz, ihiz, z, descz, work, lwork, iwork, liwork )
```

```
call pdlaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, desch, iloz, ihiz, z, descz, work, lwork, iwork, liwork )
```

Description

This auxiliary subroutine called by p?laqr0 performs a single small-bulge multi-shift QR sweep by chasing separated groups of bulges along the main block diagonal of a Hessenberg matrix *H*.

Input Parameters

wantt (global) LOGICAL scalar

wantt= .TRUE. if the quasi-triangular Schur factor is being computed. *wantt* is set to .FALSE. otherwise.

wantz (global) LOGICAL scalar

wantz= .TRUE. if the orthogonal Schur factor is being computed. *wantz* is set to .FALSE. otherwise.

kacc22 (global) INTEGER

Value 0, 1, or 2. Specifies the computation mode of far-from-diagonal orthogonal updates.

= 0: p?laqr5 does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries.

= 1: p?laqr5 accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries.

= 2: p?laqr5 accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.

n (global) INTEGER scalar

	The order of the Hessenberg matrix *H* and, if *wantz*is .TRUE., the order of the orthogonal matrix *Z*.
ktop, *kbot*	(global) INTEGER scalar These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either *ktop* = 1 or *H*(*ktop*,*ktop*-1) = 0 and either *kbot* = *n* or *H*(*kbot*+1,*kbot*) = 0.
nshfts	(global) INTEGER scalar *nshfts* gives the number of simultaneous shifts. *nshfts* must be positive and even.
sr, *si*	REAL for pslaqr5 DOUBLE PRECISION for pdlaqr5 (global) Array of size *nshfts* *sr* contains the real parts and *si* contains the imaginary parts of the *nshfts* shifts of origin that define the multi-shift QR sweep.
h	REAL for pslaqr5 DOUBLE PRECISION for pdlaqr5 (local) Array of size (*lld_h*,$LOC_c(n)$) On input *h* contains a Hessenberg matrix *H*.
desch	(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *H* .
iloz, *ihiz*	(global) INTEGER Specify the rows of the matrix *Z* to which transformations must be applied if *wantz*is .TRUE.. $1 \le iloz \le ihiz \le n$
z	REAL for pslaqr5 DOUBLE PRECISION for pdlaqr5 (local) array of size (*lld_z*,$LOC_c(n)$) If *wantz*= .TRUE., then the QR Sweep orthogonal similarity transformation is accumulated into the matrix *Z*(*iloz*:*ihiz*,*kbot*:*ktop*) from the right. If *wantz*= .FALSE., then *z* is unreferenced.
descz	(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*.
work	REAL for pslaqr5 DOUBLE PRECISION for pdlaqr5 (local workspace) array of size *lwork*
lwork	(local) INTEGER

	The size of the *work* array (*lwork*≥1). If *lwork*=-1, then a workspace query is assumed.
iwork	(local workspace) INTEGER array of size *liwork*
liwork	(local) INTEGER The size of the *iwork* array (*liwork*≥1). If *liwork*=-1, then a workspace query is assumed.

Output Parameters

h	A multi-shift QR sweep with shifts *sr*(*j*)+*i***si*(*j*) is applied to the isolated diagonal block in rows and columns *ktop* through *kbot* of the matrix *H*.
z	If *wantz*is .TRUE., *z* is updated with transformations applied only to the submatrix *Z*(*iloz*:*ihiz*,*kbot*:*ktop*).
work(1)	On exit, if *info* = 0, *work*(1) returns the optimal *lwork*.
iwork(1)	On exit, if *info* = 0, *iwork*(1) returns the optimal *liwork*.

p?laqsy

Scales a symmetric/Hermitian matrix, using scaling factors computed by p?poequ *.*

Syntax

```
call pslaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pdlaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pclaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pzlaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
```

Description

The p?laqsyroutine equilibrates a symmetric distributed matrix sub(*A*) = *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) using the scaling factors in the vectors *sr* and *sc*. The scaling factors are computed by p?poequ.

Input Parameters

uplo	(global) CHARACTER. Specifies the upper or lower triangular part of the symmetric distributed matrix sub(*A*) is to be referenced: = 'U': Upper triangular part; = 'L': Lower triangular part.
n	(global) INTEGER. The order of the distributed matrix sub(*A*). *n* ≥ 0.
a	(local).

REAL for pslaqsy

DOUBLE PRECISION for pdlaqsy

COMPLEX for pclaqsy

COMPLEX*16 for pzlaqsy.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)).

On entry, this array contains the local pieces of the distributed matrix sub(*A*). On entry, the local pieces of the distributed symmetric matrix sub(*A*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*A*) contains the upper triangular part of the matrix, and the strictly lower triangular part of sub(*A*) is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the matrix, and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja*

(global) INTEGER.

The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A.

sr

(local)

REAL for pslaqsy

DOUBLE PRECISION for pdlaqsy

COMPLEX for pclaqsy

COMPLEX*16 for pzlaqsy.

Array of size *LOCr*(*m_a*). The scale factors for *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1). *sr* is aligned with the distributed matrix *A*, and replicated across every process column. *sr* is tied to the distributed matrix *A*.

sc

(local)

REAL for pslaqsy

DOUBLE PRECISION for pdlaqsy

COMPLEX for pclaqsy

COMPLEX*16 for pzlaqsy.

Array of size *LOCc*(*m_a*). The scale factors for *A* (*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1). *sc* is aligned with the distributed matrix *A*, and replicated across every process column. *sc* is tied to the distributed matrix *A*.

scond

(global). REAL for pslaqsy

DOUBLE PRECISION for pdlaqsy

COMPLEX for pclaqsy

COMPLEX*16 for pzlaqsy.

Ratio of the smallest *sr*(*i*) (respectively *sc*(*j*)) to the largest *sr*(*i*) (respectively *sc*(*j*)), with *ia* ≤ *i* ≤ *ia*+*n*-1 and *ja* ≤ *j* ≤ *ja*+*n*-1.

amax (global).

`REAL` for `pslaqsy`

`DOUBLE PRECISION` for `pdlaqsy`

`COMPLEX` for `pclaqsy`

`COMPLEX*16` for `pzlaqsy`.

Absolute value of largest distributed submatrix entry.

Output Parameters

a On exit,

if *equed* = `'Y'`, the equilibrated matrix:

`diag(`*sr*`(`*ia*`:`*ia*`+`*n*`-1)) * sub(`*A*`) * diag(`*sc*`(`*ja*`:`*ja*`+`*n*`-1))`.

equed (global)`CHARACTER*1`.

Specifies whether or not equilibration was done.

= `'N'`: No equilibration.

= `'Y'`: Equilibration was done, that is, sub(*A*) has been replaced by:

`diag(`*sr*`(`*ia*`:`*ia*`+`*n*`-1)) * sub(`*A*`) * diag(`*sc*`(`*ja*`:`*ja*`+`*n*`-1))`.

p?lared1d

Redistributes an array assuming that the input array, bycol, is distributed across rows and that all process columns contain the same copy of bycol.

Syntax

```
call pslared1d(n, ia, ja, desc, bycol, byall, work, lwork)
call pdlared1d(n, ia, ja, desc, bycol, byall, work, lwork)
```

Description

The `p?lared1d`routine redistributes a 1D array. It assumes that the input array *bycol* is distributed across rows and that all process column contain the same copy of *bycol*. The output array *byall* is identical on all processes and contains the entire array.

Input Parameters

np = Number of local rows in *bycol*()

n (global) `INTEGER`.

The number of elements to be redistributed. *n*≥ `0`.

ia, *ja* (global) `INTEGER`. *ia*, *ja* must be equal to 1.

desc (local) INTEGER array of size 9. A 2D array descriptor, which describes *bycol*.

bycol (local).

REAL for pslared1d

DOUBLE PRECISION for pdlared1d

COMPLEX for pclared1d

COMPLEX*16 for pzlared1d.

Distributed block cyclic array of global size *n* and of local size *np*. *bycol* is distributed across the process rows. All process columns are assumed to contain the same value.

work (local).

REAL for pslared1d

DOUBLE PRECISION for pdlared1d

COMPLEX for pclared1d

COMPLEX*16 for pzlared1d.

size *lwork*. Used to hold the buffers sent from one process to another.

lwork (local)

INTEGER. The size of the *work* array. *lwork* ≥ numroc(*n*, *desc*(*nb_*), 0, 0, *npcol*).

Output Parameters

byall (global). REAL for pslared1d

DOUBLE PRECISION for pdlared1d

COMPLEX for pclared1d

COMPLEX*16 for pzlared1d.

Global size *n*, local size *n*. *byall* is exactly duplicated on all processes. It contains the same values as *bycol*, but it is replicated across all processes rather than being distributed.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lared2d

Redistributes an array assuming that the input array byrow is distributed across columns and that all process rows contain the same copy of byrow.

Syntax

```
call pslared2d(n, ia, ja, desc, byrow, byall, work, lwork)
call pdlared2d(n, ia, ja, desc, byrow, byall, work, lwork)
```

Description

The p?lared2droutine redistributes a 1D array. It assumes that the input array *byrow* is distributed across columns and that all process rows contain the same copy of *byrow*. The output array *byall* will be identical on all processes and will contain the entire array.

Input Parameters

np = Number of local rows in *byrow*()

n	(global) INTEGER. The number of elements to be redistributed. *n*≥ 0.
ia, *ja*	(global) INTEGER. *ia*, *ja* must be equal to 1.
desc	(local) INTEGER array of size *dlen_*. A 2D array descriptor, which describes *byrow*.
byrow	(local). REAL for pslared2d DOUBLE PRECISION for pdlared2d COMPLEX for pclared2d COMPLEX*16 for pzlared2d. Distributed block cyclic array of global size *n* and of local size *np*. *byrow* is distributed across the process columns. All process rows are assumed to contain the same value.
work	(local). REAL for pslared2d DOUBLE PRECISION for pdlared2d COMPLEX for pclared2d COMPLEX*16 for pzlared2d. size *lwork*. Used to hold the buffers sent from one process to another.
lwork	(local) INTEGER. The size of the *work* array. *lwork* ≥ numroc(*n*, *desc*(*nb_*), 0, 0, *npcol*).

Output Parameters

byall	(global). REAL for pslared2d DOUBLE PRECISION for pdlared2d COMPLEX for pclared2d COMPLEX*16 for pzlared2d. Global size *n*, local size *n*. *byall* is exactly duplicated on all processes. It contains the same values as *byrow*, but it is replicated across all processes rather than being distributed.

p?larf

Applies an elementary reflector to a general rectangular matrix.

Syntax

```
call pslarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pdlarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pclarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
```

Description

The p?larfroutine applies a real/complex elementary reflector Q (or Q^T) to a real/complex m-by-n distributed matrix sub(C) = $C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

```
Q = I-tau*v*v',
```

where *tau* is a real/complex scalar and v is a real/complex vector.

If $tau = 0$, then Q is taken to be the unit matrix.

Input Parameters

side (global). CHARACTER.

= 'L': form Q*sub(C),

= 'R': form sub(C)*Q, $Q=Q^T$.

m (global) INTEGER.

The number of rows in the distributed submatrix sub(A). $(m \geq 0)$.

n (global) INTEGER.

The number of columns in the distributed submatrix sub(A). $(n \geq 0)$.

v (local).

REAL for pslarf

DOUBLE PRECISION for pdlarf

COMPLEX for pclarf

COMPLEX*16 for pzlarf.

Pointer into the local memory to an array of size (*lld_v*,*), containing the local pieces of the global distributed matrix V representing the Householder transformation Q,

$V(iv:iv+m-1, jv)$ if $side$ = 'L' and $incv = 1$,

$V(iv, jv:jv+m-1)$ if $side$ = 'L' and $incv = m\_v$,

$V(iv:iv+n-1, jv)$ if $side$ = 'R' and $incv = 1$,

$V(iv, jv:jv+n-1)$ if $side$ = 'R' and $incv = m\_v$.

The array v is the representation of Q. v is not used if $tau = 0$.

iv, *jv*

(global) INTEGER. The row and column indices in the global matrix *V* indicating the first row and the first column of the matrix sub(*V*), respectively.

descv

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix V.

incv

(global) INTEGER.

The global increment for the elements of *V*. Only two values of *incv* are supported in this version, namely 1 and *m_v*.

incv must not be zero.

tau

(local).

REAL for pslarf

DOUBLE PRECISION for pdlarf

COMPLEX for pclarf

COMPLEX*16 for pzlarf.

Array of size *LOCc*(*jv*) if *incv* = 1, and *LOCr*(*iv*) otherwise. This array contains the Householder scalars related to the Householder vectors.

tau is tied to the distributed matrix *V*.

c

(local).

REAL for pslarf

DOUBLE PRECISION for pdlarf

COMPLEX for pclarf

COMPLEX*16 for pzlarf.

Pointer into the local memory to an array of size (*lld_c*, *LOCc*(*jc* +*n*-1)), containing the local pieces of sub(*C*).

ic, *jc*

(global) INTEGER.

The row and column indices in the global matrix *C* indicating the first row and the first column of the matrix sub(*C*), respectively.

descc

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work

(local).

REAL for pslarf

DOUBLE PRECISION for pdlarf

COMPLEX for pclarf

COMPLEX*16 for pzlarf.

Array of size *lwork*.

If *incv* = 1,

if *side* = 'L',

if *ivcol* = *iccol*,

lwork≥*nqc*0
else
lwork≥*mpc*0 + max(1, *nqc*0)
end if
else if *side* = 'R' ,
lwork≥*nqc*0 + max(max(1, *mpc*0), numroc(numroc(*n*+
icoffc,*nb_v*,0,0,*npcol*),*nb_v*,0,0,*lcmq*))
end if
else if *incv* = *m_v*,
if *side* = 'L',
lwork≥*mpc*0 + max(max(*1*, *nqc*0), numroc(
numroc(*m*+*iroffc*,*mb_v*,0,0,*nprow*),*mb_v*,0,0, *lcmp*))
else if *side* = 'R',
if *ivrow* = *icrow*,
lwork≥*mpc*0
else
lwork≥*nqc*0 + max(*1*, *mpc*0)
end if
end if
end if,

where *lcm* is the least common multiple of *nprow* and *npcol* and *lcm* = *ilcm*(*nprow*, *npcol*), *lcmp* = *lcm*/*nprow*, *lcmq* = *lcm*/*npcol*,

iroffc = mod(*ic*-1, *mb_c*), *icoffc* = *mod*(*jc*-1, *nb_c*),

icrow = indxg2p(*ic*, *mb_c*, *myrow*, *rsrc_c*, *nprow*),

iccol = indxg2p(*jc*, *nb_c*, *mycol*, *csrc_c*, *npcol*),

*mpc*0 = numroc(*m*+*iroffc*, *mb_c*, *myrow*, *icrow*, *nprow*),

*nqc*0 = numroc(*n*+*icoffc*, *nb_c*, *mycol*, *iccol*, *npcol*),

ilcm, indxg2p, and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

c (local).

On exit, sub(*C*) is overwritten by the *Q**sub(*C*) if *side* = 'L',

or sub(*C*) * *Q* if *side* = 'R'.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?larfb

Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.

Syntax

call pslarfb(*side*, *trans*, *direct*, *storev*, *m*, *n*, *k*, *v*, *iv*, *jv*, *descv*, *t*, *c*, *ic*, *jc*, *descc*, *work*)

call pdlarfb(*side*, *trans*, *direct*, *storev*, *m*, *n*, *k*, *v*, *iv*, *jv*, *descv*, *t*, *c*, *ic*, *jc*, *descc*, *work*)

call pclarfb(*side*, *trans*, *direct*, *storev*, *m*, *n*, *k*, *v*, *iv*, *jv*, *descv*, *t*, *c*, *ic*, *jc*, *descc*, *work*)

call pzlarfb(*side*, *trans*, *direct*, *storev*, *m*, *n*, *k*, *v*, *iv*, *jv*, *descv*, *t*, *c*, *ic*, *jc*, *descc*, *work*)

Description

The p?larfbroutine applies a real/complex block reflector Q or its transpose Q^T/conjugate transpose Q^H to a real/complex distributed m-by-n matrix sub(C) = $C(ic:ic+m-1, jc:jc+n-1)$ from the left or the right.

Input Parameters

side (global) CHARACTER.

if *side* = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the Left;

if *side* = 'R': apply Q or $Q^T$for real flavors (Q^H for complex flavors) from the Right.

trans (global) CHARACTER.

if *trans* = 'N': no transpose, apply Q;

for real flavors, if *trans*='T': transpose, apply Q^T

for complex flavors, if *trans* = 'C': conjugate transpose, apply Q^H;

direct (global) CHARACTER. Indicates how Q is formed from a product of elementary reflectors.

if *direct* = 'F': $Q = H(1)*H(2)*...*H(k)$ (Forward)

if *direct* = 'B': $Q = H(k)*...*H(2)*H(1)$ (Backward)

storev (global) CHARACTER.

Indicates how the vectors that define the elementary reflectors are stored:

if *storev* = 'C': Columnwise

if *storev* = 'R': Rowwise.

m (global) INTEGER.

The number of rows in the distributed matrix sub(C). $(m \geq 0)$.

n (global) INTEGER.

The number of columns in the distributed matrix sub(C). $(n \geq 0)$.

k (global) INTEGER.

The order of the matrix T.

v (local).

REAL for pslarfb

DOUBLE PRECISION for pdlarfb

COMPLEX for pclarfb

COMPLEX*16 for pzlarfb.

Pointer into the local memory to an array of size

(*lld_v*, *LOCc*(*jv*+*k*-1)) if *storev* = 'C',

(*lld_v*, *LOCc*(*jv*+*m*-1)) if *storev* = 'R' and *side* = 'L',

(*lld_v*, *LOCc*(*jv*+*n*-1)) if *storev* = 'R' and *side* = 'R'.

It contains the local pieces of the distributed vectors *V* representing the Householder transformation.

if *storev* = 'C' and *side* = 'L', *lld_v* ≥ max(1,*LOCr*(*iv*+*m*-1));

if *storev* = 'C' and *side* = 'R', *lld_v* ≥ max(1,*LOCr*(*iv*+*n*-1));

if *storev* = 'R', *lld_v*≥*LOCr*(*jv*+*k*-1).

iv, *jv* (global) INTEGER.

The row and column indices in the global matrix *V* indicating the first row and the first column of the matrix sub(*V*), respectively.

descv (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *V*.

c (local).

REAL for pslarfb

DOUBLE PRECISION for pdlarfb

COMPLEX for pclarfb

COMPLEX*16 for pzlarfb.

Pointer into the local memory to an array of size (*lld_c*, *LOCc*(*jc* +*n*-1)), containing the local pieces of sub(*C*).

ic, *jc* (global) INTEGER. The row and column indices in the global matrix *C* indicating the first row and the first column of the matrix sub(*C*), respectively.

descc (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work (local).

REAL for pslarfb

DOUBLE PRECISION for pdlarfb

COMPLEX for pclarfb

COMPLEX*16 for pzlarfb.

Workspace array of size *lwork*.

If *storev* = 'C',

if *side* = 'L',

lwork≥ (*nqc*0 + *mpc*0) * *k*

else if *side* = 'R',

lwork ≥ (*nqc*0 + max(*npv*0 + numroc(numroc(*n* +

icoffc, *nb_v*, 0, 0, *npcol*), *nb_v*, 0, 0, *lcmq*),

*mpc*0)) * *k*

end if

else if *storev* = 'R' ,

if *side* = 'L' ,

lwork≥ (*mpc*0 + max(*mqv*0 + numroc(numroc(*m* +

iroffc, *mb_v*, 0, 0, *nprow*), *mb_v*, 0, 0, *lcmp*),

*nqc*0)) * *k*

else if *side* = 'R',

lwork ≥ (*mpc*0 + *nqc*0) * *k*

end if

end if,

where

lcmq = *lcm* / *npcol* with *lcm* = iclm(*nprow*, *npcol*),

iroffv = mod(*iv*-1, *mb_v*), *icoffv* = mod(*jv*-1, *nb_v*),

ivrow = indxg2p(*iv*, *mb_v*, *myrow*, *rsrc_v*, *nprow*),

ivcol = indxg2p(*jv*, *nb_v*, *mycol*, *csrc_v*, *npcol*),

MqV0 = numroc(*m*+*icoffv*, *nb_v*, *mycol*, *ivcol*, *npcol*),

NpV0 = numroc(*n*+*iroffv*, *mb_v*, *myrow*, *ivrow*, *nprow*),

iroffc = mod(*ic*-1, *mb_c*), *icoffc* = mod(*jc*-1, *nb_c*),

icrow = indxg2p(*ic*, *mb_c*, *myrow*, *rsrc*_c, *nprow*),

iccol = indxg2p(*jc*, *nb_c*, *mycol*, *csrc*_c, *npcol*),

MpC0 = numroc(*m*+*iroffc*, *mb_c*, *myrow*, *icrow*, *nprow*),

NpC0 = numroc(*n*+*icoffc*, *mb_c*, *myrow*, *icrow*, *nprow*),

NqC0 = numroc(*n*+*icoffc*, *nb_c*, *mycol*, *iccol*, *npcol*),

ilcm, indxg2p, and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

t (local).

`REAL` for `pslarfb`

`DOUBLE PRECISION` for `pdlarfb`

`COMPLEX` for `pclarfb`

`COMPLEX*16` for `pzlarfb`.

Array of size `( mb_v, mb_v)` if `storev = 'R'`, and `( nb_v, nb_v)` if `storev = 'C'`. The triangular matrix *t* is the representation of the block reflector.

c (local).

On exit, sub(*C*) is overwritten by the `Q*sub(C)`, or `Q'*sub(C)`, or `sub(C)*Q`, or `sub(C)*Q'`. *Q*′ is transpose (conjugate transpose) of *Q*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?larfc

Applies the conjugate transpose of an elementary reflector to a general matrix.

Syntax

```
call pclarfc(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarfc(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
```

Description

The `p?larfc`routine applies a complex elementary reflector Q^H to a complex *m*-by-*n* distributed matrix sub(*C*) = `C(ic:ic+m-1, jc:jc+n-1)`, from either the left or the right. *Q* is represented in the form

```
Q = i-tau*v*v',
```

where *tau* is a complex scalar and *v* is a complex vector.

If `tau = 0`, then *Q* is taken to be the unit matrix.

Input Parameters

side (global) `CHARACTER`.

if `side = 'L'`: form Q^H`*sub(C)` ;

if `side = 'R'`: form sub `(C)*`Q^H.

m (global) `INTEGER`.

The number of rows in the distributed matrix sub(*C*). `(m ≥ 0)`.

n (global) `INTEGER`.

The number of columns in the distributed matrix sub(*C*). `(n ≥ 0)`.

v (local).

`COMPLEX` for `pclarfc`

COMPLEX*16 for pzlarfc.

Pointer into the local memory to an array of size (*lld_v*,*), containing the local pieces of the global distributed matrix *V* representing the Householder transformation *Q*,

V(*iv*:*iv*+*m*-1, *jv*) if *side* = 'L' and *incv* = 1,

V(*iv*, *jv*:*jv*+*m*-1) if *side* = 'L' and *incv* = *m_v*,

V(*iv*:*iv*+*n*-1, *jv*) if *side* = 'R' and *incv* = 1,

V(*iv*, *jv*:*jv*+*n*-1) if *side* = 'R' and *incv* = *m_v*.

The array *v* is the representation of *Q*. *v* is not used if *tau* = 0.

iv, *jv* (global) INTEGER.

The row and column indices in the global matrix *V* indicating the first row and the first column of the matrix sub(*V*), respectively.

descv (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *V*.

incv (global) INTEGER.

The global increment for the elements of *v*. Only two values of *incv* are supported in this version, namely 1 and *m_v*.

incv must not be zero.

tau (local)

COMPLEX for pclarfc

COMPLEX*16 for pzlarfc.

Array of size *LOCc*(*jv*) if *incv* = 1, and *LOCr*(*iv*) otherwise. This array contains the Householder scalars related to the Householder vectors.

tau is tied to the distributed matrix *V*.

c (local).

COMPLEX for pclarfc

COMPLEX*16 for pzlarfc.

Pointer into the local memory to an array of size (*lld_c*, *LOCc*(*jc*+*n*-1)), containing the local pieces of sub(*C*).

ic, *jc* (global) INTEGER.

The row and column indices in the global matrix *C* indicating the first row and the first column of the matrix sub(*C*), respectively.

descc (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work (local).

COMPLEX for pclarfc

COMPLEX*16 for pzlarfc.

Workspace array of size *lwork*.

If *incv* = 1,
 if *side* = 'L' ,
  if *ivcol* = *iccol*,
   lwork ≥ *nqc*0
  else
   lwork ≥ *mpc*0 + max(1, *nqc*0)
  end if
 else if *side* = 'R',
  lwork ≥ *nqc*0 + max(max(1, *mpc*0), numroc(numroc(
   n+*icoffc*,*nb_v*,0,0,*npcol*), *nb_v*,0,0,*lcmq*))
 end if
else if *incv* = *m_v*,
 if *side* = 'L',
  lwork ≥ *mpc*0 + max(max(1, *nqc*0), numroc(numroc(
   m+*iroffc*,*mb_v*,0,0,*nprow*),*mb_v*,0,0,*lcmp*))
 else if *side* = 'R' ,
  if *ivrow* = *icrow*,
   lwork ≥ *mpc*0
  else
   lwork ≥ *nqc*0 + max(1, *mpc*0)
  end if
 end if
end if,

where *lcm* is the least common multiple of *nprow* and *npcol* and *lcm* = ilcm(*nprow*, *npcol*),

lcmp = *lcm*/*nprow*, *lcmq* = *lcm*/*npcol*,

iroffc = mod(*ic*-1, *mb_c*), *icoffc* = mod(*jc*-1, *nb_c*),

icrow = indxg2p(*ic*, *mb_c*, *myrow*, *rsrc_c*, *nprow*),

iccol = indxg2p(*jc*, *nb_c*, *mycol*, *csrc_c*, *npcol*),

*mpc*0 = numroc(*m*+*iroffc*, *mb_c*, *myrow*, *icrow*, *nprow*),

*nqc*0 = numroc(*n*+*icoffc*, *nb_c*, *mycol*, *iccol*, *npcol*),

ilcm, indxg2p, and numroc are ScaLAPACK tool functions;*myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

c (local).

On exit, sub(*C*) is overwritten by the Q^H*sub(*C*) if *side* = 'L', or sub(*C*) * Q^H if *side* = 'R'.

p?larfg

Generates an elementary reflector (Householder matrix).

Syntax

```
call pslarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pdlarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pclarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pzlarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
```

Description

The p?larfgroutine generates a real/complex elementary reflector *H* of order *n*, such that

$$H * \mathrm{sub}(X) = H * \begin{pmatrix} x(iax, jax) \\ x \end{pmatrix} = \begin{pmatrix} alpha \\ 0 \end{pmatrix}, \quad H' * H = I,$$

where *alpha* is a scalar (a real scalar - for complex flavors), and sub(*X*) is an (*n*-1)-element real/complex distributed vector *X*(*ix*:*ix*+*n*-2, *jx*) if *incx* = 1 and *X*(*ix*, *jx*:*jx*+*n*-2) if *incx* = *m_x*. *H* is represented in the form

$$H = I - tau * \begin{pmatrix} 1 \\ v \end{pmatrix} * (1 \; v')$$

where *tau* is a real/complex scalar and *v* is a real/complex (*n*-1)-element vector. Note that *H* is not Hermitian.

If the elements of sub(*X*) are all zero (and *X*(*iax*, *jax*) is real for complex flavors), then *tau* = 0 and *H* is taken to be the unit matrix.

Otherwise 1 ≤ real(*tau*) ≤ 2 and abs(*tau*-1) ≤ 1.

Input Parameters

n — (global) INTEGER.

The global order of the elementary reflector. *n* ≥ 0.

iax, *jax* — (global) INTEGER.

The global row and column indices of *X*(*iax*, *jax*) in the global matrix *X*.

x (local).

REAL for pslarfg

DOUBLE PRECISION for pdlarfg

COMPLEX for pclarfg

COMPLEX*16 for pzlarfg.

Pointer into the local memory to an array of size (*lld_x*, *). This array contains the local pieces of the distributed vector sub(*X*). Before entry, the incremented array sub(*X*) must contain vector *x*.

ix, *jx* (global) INTEGER.

The row and column indices in the global matrix *X* indicating the first row and the first column of sub(*X*), respectively.

descx (global and local) INTEGER.

Array of size *dlen_*. The array descriptor for the distributed matrix *X*.

incx (global) INTEGER.

The global increment for the elements of *x*. Only two values of *incx* are supported in this version, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

alpha (local)

REAL for pslafg

DOUBLE PRECISION for pdlafg

COMPLEX for pclafg

COMPLEX*16 for pzlafg.

On exit, *alpha* is computed in the process scope having the vector sub(*X*).

x (local).

On exit, it is overwritten with the vector *v*.

tau (local).

REAL for pslarfg

DOUBLE PRECISION for pdlarfg

COMPLEX for pclarfg

COMPLEX*16 for pzlarfg.

Array of size *LOCc*(*jx*) if *incx* = 1, and *LOCr*(*ix*) otherwise. This array contains the Householder scalars related to the Householder vectors.

tau is tied to the distributed matrix *X*.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?larft

Forms the triangular vector `T` *of a block reflector* `H=I-V*T*V^H`.

Syntax

```
call pslarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pdlarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pclarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pzlarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
```

Description

The `p?larft`routine forms the triangular factor *T* of a real/complex block reflector *H* of order *n*, which is defined as a product of *k* elementary reflectors.

If `direct = 'F'`, `H = H(1)*H(2)...*H(k)`, and *T* is upper triangular;

If `direct = 'B'`, `H = H(k)*...*H(2)*H(1)`, and *T* is lower triangular.

If `storev = 'C'`, the vector which defines the elementary reflector `H(i)` is stored in the *i*-th column of the distributed matrix *V*, and

`H = I-V*T*V'`

If `storev = 'R'`, the vector which defines the elementary reflector `H(i)` is stored in the *i*-th row of the distributed matrix *V*, and

`H = I-V'*T*V`.

Input Parameters

direct

(global) `CHARACTER*1`.

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

if `direct = 'F'`: `H = H(1)*H(2)*...*H(k)` (forward)

if `direct = 'B'`: `H = H(k)*...*H(2)*H(1)` (backward).

storev

(global) `CHARACTER*1`.

Specifies how the vectors that define the elementary reflectors are stored (See *Application Notes* below):

if `storev = 'C'`: columnwise;

if `storev = 'R'`: rowwise.

n

(global) `INTEGER`.

The order of the block reflector *H*. $n \geq 0$.

k

(global) `INTEGER`.

The order of the triangular factor *T*, is equal to the number of elementary reflectors.

$1 \leq k \leq mb\_v$ (= nb_v).

v

`REAL` for `pslarft`

DOUBLE PRECISION for pdlarft

COMPLEX for pclarft

COMPLEX*16 for pzlarft.

Pointer into the local memory to an array of local size

(*LOCr*(*iv*+*n*-1), *LOCc*(*jv*+*k*-1)) if *storev* = 'C', and

(*LOCr*(*iv*+*k*-1), *LOCc*(*jv*+*n*-1)) if *storev* = 'R'.

The distributed matrix *V* contains the Householder vectors. (See *Application Notes* below).

iv, *jv*

(global) INTEGER.

The row and column indices in the global matrix *V* indicating the first row and the first column of the matrix sub(*V*), respectively.

descv

(local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *V*.

tau

(local)

REAL for pslarft

DOUBLE PRECISION for pdlarft

COMPLEX for pclarft

COMPLEX*16 for pzlarft.

Array of size *LOCr*(*iv*+*k*-1) if *incv* = *m_v*, and *LOCc*(*jv*+*k*-1) otherwise. This array contains the Householder scalars related to the Householder vectors.

tau is tied to the distributed matrix *V*.

work

(local).

REAL for pslarft

DOUBLE PRECISION for pdlarft

COMPLEX for pclarft

COMPLEX*16 for pzlarft.

Workspace array of size *k**(*k* -1)/2.

Output Parameters

v

REAL for pslarft

DOUBLE PRECISION for pdlarft

COMPLEX for pclarft

COMPLEX*16 for pzlarft.

t

(local)

REAL for pslarft

DOUBLE PRECISION for pdlarft

COMPLEX for pclarft

COMPLEX*16 for pzlarft.

Array of size (*nb_v*, *nb_v*) if *storev* = 'C', and (*mb_v*, *mb_v*) otherwise. It contains the *k*-by-*k* triangular factor of the block reflector associated with *v*. If *direct* = 'F', *t* is upper triangular;

if *direct* = 'B', *t* is lower triangular.

Application Notes

The shape of the matrix *V* and the storage of the vectors that define the *H(i)* is best illustrated by the following example with *n* = 5 and *k* = 3. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct = 'F' and *storev* = 'C':

$$V(iv:iv+n-1,\ jv:jv+k-1) = \begin{bmatrix} 1 & & \\ v1 & 1 & \\ v1 & v2 & 1 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \end{bmatrix}$$

direct = 'F' and *storev* = 'R'

$$V(iv:iv+k-1,\ jv:jv+n-1) = \begin{bmatrix} 1 & v1 & v1 & v1 \\ & 1 & v2 & v2 \\ & & 1 & v3 \end{bmatrix}$$

direct = 'B' and *storev* = 'C'

$$V(iv:iv+n-1,\ jv:jv+k-1) = \begin{bmatrix} v1 & v2v & v3 \\ v1 & v2 & v3 \\ 1 & v2 & v3 \\ & 1 & v3 \\ & & 1 \end{bmatrix}$$

direct = 'B' and *storev* = 'R'

$$V(iv:iv+k-1,\ jv:jv+n-1) = \begin{bmatrix} v1 & v1 & 1 & & \\ v2 & v2 & v2 & 1 & \\ v3 & v3 & v3 & v3 & 1 \end{bmatrix}$$

p?larz

Applies an elementary reflector as returned by p?tzrzf *to a general matrix.*

Syntax

```
call pslarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pdlarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pclarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
```

Description

The p?larzroutine applies a real/complex elementary reflector *Q* (or Q^T) to a real/complex *m*-by-*n* distributed matrix sub(*C*) = *C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1), from either the left or the right. *Q* is represented in the form

`Q = I-tau*v*v'`,

where *tau* is a real/complex scalar and *v* is a real/complex vector.

If `tau = 0`, then *Q* is taken to be the unit matrix.

Q is a product of *k* elementary reflectors as returned by `p?tzrzf`.

Input Parameters

side (global) `CHARACTER`.

if `side = 'L'`: form `Q*sub(C)`,

if `side = 'R'`: form `sub(C)*Q`, `Q = Q^T` (for real flavors).

m (global) `INTEGER`.

The number of rows in the distributed matrix sub(*C*). `(m≥ 0)`.

n (global) `INTEGER`.

The number of columns in the distributed matrix sub(*C*). `(n≥ 0)`.

l (global) `INTEGER`.

The columns of the distributed matrix sub(*A*) containing the meaningful part of the Householder reflectors. If `side = 'L'`, `m≥ l≥` 0,

if `side = 'R'`, `n≥l ≥ 0`.

v (local).

`REAL` for `pslarz`

`DOUBLE PRECISION` for `pdlarz`

`COMPLEX` for `pclarz`

`COMPLEX*16` for `pzlarz`.

Pointer into the local memory to an array of size (*lld_v*,*) containing the local pieces of the global distributed matrix *V* representing the Householder transformation *Q*,

V`(iv:iv+l-1, jv)` if `side = 'L'` and `incv = 1`,

V`(iv, jv:jv+l-1)` if `side = 'L'` and `incv = m_v`,

V`(iv:iv+l-1, jv)` if `side = 'R'` and `incv = 1`,

V`(iv, jv:jv+l-1)` if `side = 'R'` and `incv = m_v`.

The vector `v` in the representation of *Q*. `v` is not used if `tau = 0`.

iv, *jv* (global) `INTEGER`. The row and column indices in the global distributed matrix *V* indicating the first row and the first column of the matrix sub(*V*), respectively.

descv (global and local) `INTEGER` array of size *dlen_*. The array descriptor for the distributed matrix *V*.

incv (global) `INTEGER`.

The global increment for the elements of *V*. Only two values of *incv* are supported in this version, namely 1 and *m_v*.

incv must not be zero.

tau (local)

REAL for pslarz

DOUBLE PRECISION for pdlarz

COMPLEX for pclarz

COMPLEX*16 for pzlarz.

Array of size *LOCc*(*jv*) if *incv* = 1, and *LOCr*(*iv*) otherwise. This array contains the Householder scalars related to the Householder vectors.

tau is tied to the distributed matrix *V*.

c (local).

REAL for pslarz

DOUBLE PRECISION for pdlarz

COMPLEX for pclarz

COMPLEX*16 for pzlarz.

Pointer into the local memory to an array of size (*lld_c*, *LOCc*(*jc*+*n*-1)), containing the local pieces of sub(*C*).

ic, *jc* (global) INTEGER.

The row and column indices in the global matrix *C* indicating the first row and the first column of the matrix sub(*C*), respectively.

descc (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work (local).

REAL for pslarz

DOUBLE PRECISION for pdlarz

COMPLEX for pclarz

COMPLEX*16 for pzlarz.

Array of size *lwork*

If *incv* = 1,

if *side* = 'L' ,

if *ivcol* = *iccol*,

lwork ≥ *NqC*0

else

lwork ≥ *MpC*0 + max(1, *NqC*0)

end if

else if *side* = 'R' ,

lwork ≥ *NqC*0 + max(max(1, *MpC*0), numroc(numroc(*n* +*icoffc*,*nb_v*,0,0,*npcol*),*nb_v*,0,0,*lcmq*))

end if

else if *incv* = *m_v*,

if *side* = 'L' ,

lwork ≥ *MpC*0 + max(max(1, *NqC*0), numroc(numroc(*m*+*iroffc*,*mb_v*,0,0,*nprow*),*mb_v*,0,0,*lcmp*))

else if *side* = 'R' ,

if *ivrow* = *icrow*,

lwork ≥ *MpC*0

else

lwork ≥ *NqC*0 + max(1, *MpC*0)

end if

end if

end if.

Here *lcm* is the least common multiple of *nprow* and *npcol* and

lcm = ilcm(*nprow*, *npcol*), *lcmp* = *lcm* / *nprow*,

lcmq = *lcm* / *npcol*,

iroffc = mod(*ic*-1, *mb_c*), *icoffc* = mod(*jc*-1, *nb_c*),

icrow = indxg2p(*ic*, *mb_c*, *myrow*, *rsrc_c*, *nprow*),

iccol = indxg2p(*jc*, *nb_c*, *mycol*, *csrc_c*, *npcol*),

*mpc*0 = numroc(*m*+*iroffc*, *mb_c*, *myrow*, *icrow*, *nprow*),

*nqc*0 = numroc(*n*+*icoffc*, *nb_c*, *mycol*, *iccol*, *npcol*),

ilcm, indxg2p, and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

c (local).

On exit, sub(*C*) is overwritten by the *Q**sub(*C*) if *side* = 'L', or sub(*C*)**Q* if *side* = 'R'.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?larzb

Applies a block reflector or its transpose/conjugate-transpose as returned by p?tzrzf *to a general matrix.*

Syntax

call pslarzb(*side*, *trans*, *direct*, *storev*, *m*, *n*, *k*, *l*, *v*, *iv*, *jv*, *descv*, *t*, *c*, *ic*, *jc*, *descc*, *work*)

```
call pdlarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c, ic, jc, descc, work)
call pclarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c, ic, jc, descc, work)
call pzlarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c, ic, jc, descc, work)
```

Description

The p?larzbroutine applies a real/complex block reflector Q or its transpose Q^T (conjugate transpose Q^H for complex flavors) to a real/complex distributed m-by-n matrix sub(C) = $C(ic:ic+m-1, jc:jc+n-1)$ from the left or the right.

Q is a product of k elementary reflectors as returned by p?tzrzf.

Currently, only *storev* = 'R' and *direct* = 'B' are supported.

Input Parameters

side (global) CHARACTER.

if *side* = 'L': apply Q or Q^T (Q^H for complex flavors) from the Left;

if *side* = 'R': apply Q or Q^T (Q^H for complex flavors) from the Right.

trans (global) CHARACTER.

if *trans* = 'N': No transpose, apply Q;

If *trans*='T': Transpose, apply Q^T (real flavors);

If *trans*='C': Conjugate transpose, apply Q^H (complex flavors).

direct (global) CHARACTER.

Indicates how H is formed from a product of elementary reflectors.

if *direct* = 'F': $H = H(1)*H(2)*...*H(k)$ - forward (not supported) ;

if *direct* = 'B': $H = H(k)*...*H(2)*H(1)$ - backward.

storev (global) CHARACTER.

Indicates how the vectors that define the elementary reflectors are stored:

if *storev* = 'C': columnwise (not supported).

if *storev* = 'R': rowwise.

m (global) INTEGER.

The number of rows in the distributed submatrix sub(C). $(m \geq 0)$.

n (global) INTEGER.

The number of columns in the distributed submatrix sub(C). $(n \geq 0)$.

k (global) INTEGER.

The order of the matrix T. (= the number of elementary reflectors whose product defines the block reflector).

l (global) INTEGER.

The columns of the distributed submatrix sub(*A*) containing the meaningful part of the Householder reflectors.

If *side* = 'L', $m \geq l \geq 0$,

if *side* = 'R', $n \geq l \geq 0$.

v (local).

REAL for pslarzb

DOUBLE PRECISION for pdlarzb

COMPLEX for pclarzb

COMPLEX*16 for pzlarzb.

Pointer into the local memory to an array of size (*lld_v*, *LOCc*(*jv*+*m*-1)) if *side* = 'L', (*lld_v*, *LOCc*(*jv*+*m*-1)) if *side* = 'R'.

It contains the local pieces of the distributed vectors *V* representing the Householder transformation as returned by p?tzrzf.

lld_v ≥ *LOCr*(*iv*+*k*-1).

iv, *jv* (global) INTEGER.

The row and column indices in the global matrix *V* indicating the first row and the first column of the submatrix sub(*V*), respectively.

descv (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *V*.

t (local)

REAL for pslarzb

DOUBLE PRECISION for pdlarzb

COMPLEX for pclarzb

COMPLEX*16 for pzlarzb.

Array of size *mb_v*by *mb_v*.

The lower triangular matrix *T* in the representation of the block reflector.

c (local).

REAL for pslarfb

DOUBLE PRECISION for pdlarfb

COMPLEX for pclarfb

COMPLEX*16 for pzlarfb.

Pointer into the local memory to an array of size (*lld_c*, *LOCc*(*jc*+*n*-1)).

On entry, the *m*-by-*n* distributed matrix sub(*C*).

ic, *jc* (global) INTEGER.

The row and column indices in the global matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.

descc (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work (local).

REAL for pslarzb

DOUBLE PRECISION for pdlarzb

COMPLEX for pclarzb

COMPLEX*16 for pzlarzb.

Array of size *lwork*.

```
If storev = 'C' ,
  if side = 'L' ,
    lwork≥(nqc0 + mpc0)* k
  else if side = 'R' ,
    lwork ≥ (nqc0 + max(npv0 + numroc(numroc(n+icoffc, nb_v, 0, 0,
npcol),
           nb_v, 0, 0, lcmq), mpc0))* k
  end if
else if storev = 'R' ,
  if side = 'L' ,
    lwork≥ (mpc0 + max(mqv0 + numroc(numroc(m+iroffc, mb_v, 0, 0,
nprow),
             mb_v, 0, 0, lcmp), nqc0))* k
  else if side = 'R' ,
    lwork≥ (mpc0 + nqc0) * k
  end if
  end if.
```

Here *lcmq* = *lcm*/*npcol* with *lcm* = iclm(*nprow*, *npcol*),

iroffv = mod(*iv*-1, *mb_v*), *icoffv* = mod(*jv-1*, *nb_v*),

ivrow = indxg2p(*iv*, *mb_v*, *myrow*, *rsrc_v*, *nprow*),

ivcol = indxg2p(*jv*, *nb_v*, *mycol*, *csrc_v*, *npcol*),

mqv0 = numroc(*m*+*icoffv*, *nb_v*, *mycol*, *ivcol*, *npcol*),

npv0 = numroc(*n*+*iroffv*, *mb_v*, *myrow*, *ivrow*, *nprow*),

iroffc = mod(*ic*-1, *mb_c*), *icoffc*= *mod*(*jc*-1, *nb_c*),

icrow= indxg2p(*ic*, *mb_c*, *myrow*, *rsrc_c*, *nprow*),

iccol= indxg2p(*jc*, *nb_c*, *mycol*, *csrc_c*, *npcol*),

mpc0 = numroc(*m*+*iroffc*, *mb_c*, *myrow*, *icrow*, *nprow*),

npc0 = numroc(*n*+*icoffc*, *mb_c*, *myrow*, *icrow*, *nprow*),

nqc0 = numroc(*n*+*icoffc*, *nb_c*, *mycol*, *iccol*, *npcol*),

ilcm, indxg2p, and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

c (local).

On exit, sub(*C*) is overwritten by the *Q**sub(*C*), or *Q*'*sub(*C*), or sub(*C*)**Q*, or sub(*C*)**Q*', where *Q*' is the transpose (conjugate transpose) of *Q*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?larzc

Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by p?tzrzf *to a general matrix.*

Syntax

call pclarzc(*side*, *m*, *n*, *l*, *v*, *iv*, *jv*, *descv*, *incv*, *tau*, *c*, *ic*, *jc*, *descc*, *work*)

call pzlarzc(*side*, *m*, *n*, *l*, *v*, *iv*, *jv*, *descv*, *incv*, *tau*, *c*, *ic*, *jc*, *descc*, *work*)

Description

The p?larzcroutine applies a complex elementary reflector Q^H to a complex *m*-by-*n* distributed matrix sub(*C*) = *C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1), from either the left or the right. *Q* is represented in the form

Q = *i*-*tau***v***v*',

where *tau* is a complex scalar and *v* is a complex vector.

If *tau* = 0, then *Q* is taken to be the unit matrix.

Q is a product of *k* elementary reflectors as returned by p?tzrzf.

Input Parameters

side (global) CHARACTER.

if *side* = 'L': form Q^H*sub(*C*);

if *side* = 'R': form sub(*C*)*Q^H.

m (global) INTEGER.

The number of rows in the distributed matrix sub(*C*). (*m* ≥ 0).

n (global) INTEGER.

The number of columns in the distributed matrix sub(*C*). (*n* ≥ 0).

l (global) INTEGER.

The columns of the distributed matrix sub(*A*) containing the meaningful part of the Householder reflectors.

If *side* = 'L', $m \geq l \geq 0$,

if *side* = 'R', $n \geq l \geq 0$.

v (local).

COMPLEX for pclarzc

COMPLEX*16 for pzlarzc.

Pointer into the local memory to an array of size (*lld_v*,*) containing the local pieces of the global distributed matrix *V* representing the Householder transformation *Q*,

V(*iv*:*iv*+l-1, *jv*) if *side* = 'L' and *incv* = 1,

V(*iv*, *jv*:*jv*+*l*-1) if *side* = 'L' and *incv* = *m_v*,

V(*iv*:*iv*+*l*-1, *jv*) if *side* = 'R' and *incv* = 1,

V(*iv*, *jv*:*jv*+*l*-1) if *side* = 'R' and *incv* = *m_v*.

The vector *v* in the representation of *Q*. *v* is not used if *tau* = 0.

iv, *jv* (global) INTEGER.

The row and column indices in the global matrix *V* indicating the first row and the first column of the matrix sub(*V*), respectively.

descv (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *V*.

incv (global) INTEGER.

The global increment for the elements of *V*. Only two values of *incv* are supported in this version, namely 1 and *m_v*.

incv must not be zero.

tau (local)

COMPLEX for pclarzc

COMPLEX*16 for pzlarzc.

Array of size *LOCc*(*jv*) if *incv* = 1, and *LOCr*(*iv*) otherwise. This array contains the Householder scalars related to the Householder vectors.

tau is tied to the distributed matrix *V*.

c (local).

COMPLEX for pclarzc

COMPLEX*16 for pzlarzc.

Pointer into the local memory to an array of size (*lld_c*, *LOCc*(*jc*+*n*-1)), containing the local pieces of sub(*C*).

ic, *jc* (global) INTEGER.

The row and column indices in the global matrix *C* indicating the first row and the first column of the matrix sub(*C*), respectively.

descc (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work (local).

```
If incv = 1,
  if side = 'L' ,
    if ivcol = iccol,
      lwork≥ nqc0
    else
      lwork ≥ mpc0 + max(1, nqc0)
    end if
  else if side = 'R' ,
    lwork ≥nqc0 + max(max(1, mpc0), numroc(numroc(n+icoffc, nb_v,
0, 0, npcol),
           nb_v, 0, 0, lcmq))  end if
else if incv = m_v,
  if side = 'L' ,
    lwork≥mpc0 + max(max(1, nqc0), numroc(numroc(m+iroffc, mb_v,
0, 0, nprow),
           mb_v, 0, 0, lcmp))
  else if side = 'R',
    if ivrow = icrow,
      lwork≥ mpc0
    else
      lwork≥nqc0 + max(1, mpc0)
    end if
  end if
        end if
```

Here *lcm* is the least common multiple of *nprow* and *npcol*;

lcm = ilcm(*nprow*, *npcol*), *lcmp* = *lcm*/*nprow*, *lcmq*= *lcm*/*npcol*,

iroffc = mod(*ic*-1, *mb_c*), *icoffc*= mod(*jc*-1, *nb_c*),

icrow = indxg2p(*ic*, *mb_c*, *myrow*, *rsrc_c*, *nprow*),

iccol = indxg2p(*jc*, *nb_c*, *mycol*, *csrc_c*, *npcol*),

mpc0 = numroc(*m*+*iroffc*, *mb_c*, *myrow*, *icrow*, *nprow*),

nqc0 = numroc(*n*+*icoffc*, *nb_c*, *mycol*, *iccol*, *npcol*),

ilcm, indxg2p, and numroc are ScaLAPACK tool functions;

myrow, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

c (local).

On exit, sub(*C*) is overwritten by the Q^H*sub(*C*) if *side* = 'L', or sub(*C*)*Q^H if *side* = 'R'.

p?larzt

*Forms the triangular factor T of a block reflector H=I-V*T*V^H as returned by* p?tzrzf.

Syntax

```
call pslarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pdlarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pclarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pzlarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
```

Description

The p?larztroutine forms the triangular factor *T* of a real/complex block reflector *H* of order greater than *n*, which is defined as a product of *k* elementary reflectors as returned by p?tzrzf.

If *direct* = 'F', *H* = *H*(1)**H*(2)*...**H*(*k*), and *T* is upper triangular;

If *direct* = 'B', *H* = *H*(*k*)*...**H*(2)**H*(1), and *T* is lower triangular.

If *storev* = 'C', the vector which defines the elementary reflector *H*(*i*), is stored in the *i*-th column of the array *v*, and

H = *i*-*v***t***v*'.

If *storev* = 'R', the vector, which defines the elementary reflector *H*(*i*), is stored in the *i*-th row of the array *v*, and

H = *i*-*v*'**t***v*

Currently, only *storev* = 'R' and *direct* = 'B' are supported.

Input Parameters

direct

(global) CHARACTER.

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

if *direct* = 'F': *H* = *H*(1)**H*(2)*...**H*(*k*) (Forward, not supported)

if *direct* = 'B': *H* = *H*(*k*)*...**H*(2)**H*(1) (Backward).

storev

(global) CHARACTER.

Specifies how the vectors which defines the elementary reflectors are stored:

if *storev* = 'C': columnwise (not supported);

if *storev* = 'R': rowwise.

n

(global) INTEGER.

The order of the block reflector *H*. *n* ≥ 0.

k

(global) INTEGER.

The order of the triangular factor *T* (= the number of elementary reflectors).

1≤*k*≤*mb_v*(= *nb_v*).

v

REAL for pslarzt

DOUBLE PRECISION for pdlarzt

COMPLEX for pclarzt

COMPLEX*16 for pzlarzt.

Pointer into the local memory to an array of local size (*LOCr*(*iv*+*k*-1), *LOCc*(*jv*+*n*-1)).

The distributed matrix *V* contains the Householder vectors. See *Application Notes* below.

iv, *jv*

(global) INTEGER. The row and column indices in the global matrix *V* indicating the first row and the first column of the matrix sub(*V*), respectively.

descv

(local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *V*.

tau

(local)

REAL for pslarzt

DOUBLE PRECISION for pdlarzt

COMPLEX for pclarzt

COMPLEX*16 for pzlarzt.

Array of size *LOCr*(*iv*+*k*-1) if *incv* = *m_v*, and *LOCc*(*jv*+*k*-1) otherwise. This array contains the Householder scalars related to the Householder vectors.

tau is tied to the distributed matrix *V*.

work

(local).

REAL for pslarzt

DOUBLE PRECISION for pdlarzt

COMPLEX for pclarzt

COMPLEX*16 for pzlarzt.

Workspace array of size (*k**(*k*-1)/2).

Output Parameters

v

REAL for pslarzt

DOUBLE PRECISION for pdlarzt

COMPLEX for pclarzt

COMPLEX*16 for pzlarzt.

t

(local)

REAL for pslarzt

DOUBLE PRECISION for pdlarzt

COMPLEX for pclarzt

COMPLEX*16 for pzlarzt.

Array of size *mb_v*by *mb_v*. It contains the *k*-by-*k* triangular factor of the block reflector associated with *v*. *t* is lower triangular.

Application Notes

The shape of the matrix *V* and the storage of the vectors which define the `H(i)` is best illustrated by the following example with `n = 5` and `k = 3`. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct='F' and *storev*='C'

$$v = \begin{bmatrix} v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \end{bmatrix} \\ \begin{matrix} . & . & . \\ . & . & . \\ 1 & . & . \\ & 1 & . \\ & & 1 \end{matrix}$$

direct='F' and *storev*='R':

$$\begin{bmatrix} \overbrace{\begin{matrix} v1 & v1 & v1 & v1 & v1 \\ v2 & v2 & v2 & v2 & v2 \\ v3 & v3 & v3 & v3 & v3 \end{matrix}}^{V} & \begin{matrix} . & . & . & . & 1 \\ . & . & . & 1 & \\ . & . & 1 & & \end{matrix} \end{bmatrix}$$

direct='B' and storev='C':

$$V = \begin{bmatrix} 1 & & \\ . & 1 & \\ . & . & 1 \\ . & . & . \\ . & . & . \end{bmatrix} \begin{bmatrix} v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \end{bmatrix}$$

direct='B' and storev='R':

$$\begin{bmatrix} & & & & \overbrace{\qquad\qquad\qquad\qquad}^{V} & & & & \\ 1 & . & . & . & v1 & v1 & v1 & v1 & v1 \\ . & 1 & . & . & v2 & v2 & v2 & v2 & v2 \\ . & . & 1 & . & v3 & v3 & v3 & v3 & v3 \end{bmatrix}$$

p?lascl

Multiplies a general rectangular matrix by a real scalar defined as c_{to}/c_{from}.

Syntax

```
call pslascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pdlascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pclascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pzlascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
```

Description

The `p?lascl`routine multiplies the *m*-by-*n* real/complex distributed matrix sub(*A*) denoting *A*`(ia:ia+m-1, ja:ja+n-1)` by the real/complex scalar `cto/cfrom`. This is done without over/underflow as long as the final result `cto`**A*(*i*,*j*)/`cfrom` does not over/underflow. `type` specifies that sub(*A*) may be full, upper triangular, lower triangular or upper Hessenberg.

Input Parameters

type (global) CHARACTER.

type indicates the storage type of the input distributed matrix.

if *type* = 'G': sub(*A*) is a full matrix,

if *type* = 'L': sub(*A*) is a lower triangular matrix,

if *type* = 'U': sub(*A*) is an upper triangular matrix,

if *type* = 'H': sub(*A*) is an upper Hessenberg matrix.

cfrom, *cto* (global)

REAL for pslascl/pclascl

DOUBLE PRECISION for pdlascl/pzlascl.

The distributed matrix sub(*A*) is multiplied by *cto/cfrom*. *A*(*i*,*j*) is computed without over/underflow if the final result *cto***A*(*i*,*j*)/*cfrom* can be represented without over/underflow. *cfrom* must be nonzero.

m (global) INTEGER.

The number of rows in the distributed matrix sub(*A*). (*m*≥0).

n (global) INTEGER.

The number of columns in the distributed matrix sub(*A*). (*n*≥0).

a (local input/local output)

REAL for pslascl

DOUBLE PRECISION for pdlascl

COMPLEX for pclascl

COMPLEX*16 for pzlascl.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)).

This array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER.

The column and row indices in the global matrix *A* indicating the first row and column of the matrix sub(*A*), respectively.

desca (global and local) INTEGER.

Array of size *dlen_*.The array descriptor for the distributed matrix *A*.

Output Parameters

a (local).

On exit, this array contains the local pieces of the distributed matrix multiplied by *cto/cfrom*.

info (local)

INTEGER.

if *info* = 0: the execution is successful.

if *info* < 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*),

if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lase2

Initializes an m-by-n distributed matrix.

Syntax

```
call pslase2 (uplo, m, n, alpha, beta, a, ia, ja, desca )
call pdlase2 (uplo, m, n, alpha, beta, a, ia, ja, desca )
call pclase2 (uplo, m, n, alpha, beta, a, ia, ja, desca )
call pzlase2 (uplo, m, n, alpha, beta, a, ia, ja, desca )
```

Description

p?lase2 initializes an *m*-by-*n* distributed matrix sub(*A*) denoting *A*(*ia*:*ia*+*m*-1,*ja*:*ja*+*n*-1) to *beta* on the diagonal and *alpha* on the off-diagonals. p?lase2 requires that only the dimension of the matrix operand is distributed.

Input Parameters

uplo (global)

CHARACTER.

Specifies the part of the distributed matrix sub(*A*) to be set:

= 'U': Upper triangular part is set; the strictly lower triangular part of sub(*A*) is not changed;

= 'L': Lower triangular part is set; the strictly upper triangular part of sub(*A*) is not changed;

Otherwise: All of the matrix sub(*A*) is set.

m (global)

INTEGER.

The number of rows to be operated on i.e the number of rows of the distributed submatrix sub(*A*). *m* >= 0.

n (global)

INTEGER.

The number of columns to be operated on i.e the number of columns of the distributed submatrix sub(*A*). *n* >= 0.

alpha (global)

REAL for pslase2

DOUBLE PRECISION for pdlase2

COMPLEX for pclase2

DOUBLE COMPLEX for pzlase2

The constant to which the off-diagonal elements are to be set.

beta (global)

REAL for pslase2

DOUBLE PRECISION for pdlase2

COMPLEX for pclase2

DOUBLE COMPLEX for pzlase2

The constant to which the diagonal elements are to be set.

ia (global)

INTEGER.

The row index in the global array *a* indicating the first row of sub(*A*).

ja (global)

INTEGER.

The column index in the global array *a* indicating the first column of sub(*A*).

desca (global and local)

INTEGER.

Array of size *dlen_*.

The array descriptor for the distributed matrix *A*.

Output Parameters

a (local)

REAL for pslase2

DOUBLE PRECISION for pdlase2

COMPLEX for pclase2

DOUBLE COMPLEX for pzlase2

Pointer into the local memory to an array of size (*lld_a*,*LOCc*(*ja*+*n*-1)).

This array contains the local pieces of the distributed matrix sub(*A*) to be set.

On exit, the leading *m*-by-*n* submatrix sub(*A*) is set as follows:

if *uplo* = 'U', *A*(*ia*+i-1,*ja*+j-1) = *alpha*, 1<=i<=j-1, 1<=j<=*n*,

if *uplo* = 'L', *A*(*ia*+i-1,*ja*+j-1) = *alpha*, j+1<=i<=*m*, 1<=j<=*n*,

otherwise, *A*(*ia*+i-1,*ja*+j-1) = *alpha*, 1<=i<=*m*, 1<=j<=*n*, *ia*+i != *ja*+j,

and, for all *uplo*, *A*(*ia*+i-1,*ja*+i-1) = *beta*, 1<=i<=min(*m*,*n*).

p?laset

Initializes the offdiagonal elements of a matrix to alpha and the diagonal elements to beta.

Syntax

```
call pslaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pdlaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pclaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pzlaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
```

Description

The p?lasetroutine initializes an *m*-by-*n* distributed matrix sub(*A*) denoting *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1) to *beta* on the diagonal and *alpha* on the offdiagonals.

Input Parameters

uplo

(global) CHARACTER.

Specifies the part of the distributed matrix sub(*A*) to be set:

if *uplo* = 'U': upper triangular part; the strictly lower triangular part of sub(*A*) is not changed;

if *uplo* = 'L': lower triangular part; the strictly upper triangular part of sub(*A*) is not changed.

Otherwise: all of the matrix sub(*A*) is set.

m

(global) INTEGER.

The number of rows in the distributed matrix sub(*A*). (*m*≥0).

n

(global) INTEGER.

The number of columns in the distributed matrix sub(*A*). (*n*≥0).

alpha

(global).

REAL for pslaset

DOUBLE PRECISION for pdlaset

COMPLEX for pclaset

COMPLEX*16 for pzlaset.

The constant to which the offdiagonal elements are to be set.

beta

(global).

REAL for pslaset

DOUBLE PRECISION for pdlaset

COMPLEX for pclaset

COMPLEX*16 for pzlaset.

The constant to which the diagonal elements are to be set.

Output Parameters

a (local).

`REAL` for `pslaset`

`DOUBLE PRECISION` for `pdlaset`

`COMPLEX` for `pclaset`

`COMPLEX*16` for `pzlaset`.

Pointer into the local memory to an array of size `(lld_a, LOCc(ja+n-1))`.

This array contains the local pieces of the distributed matrix sub(*A*) to be set. On exit, the leading *m*-by-*n* matrix sub(*A*) is set as follows:

if `uplo = 'U'`, *A*(`ia`+*i*-1, `ja`+*j*-1) = `alpha`, 1≤*i*≤*j*-1, 1≤*j*≤`n`,

if `uplo = 'L'`, *A*(`ia`+*i*-1, `ja`+*j*-1) = `alpha`, *j*+1≤*i*≤ `m`, 1≤*j*≤`n`,

otherwise, *A*(`ia`+*i*-1, `ja`+*j*-1) = `alpha`, 1≤*i*≤`m`, 1≤*j*≤`n`, `ia`+*i*≠`ja`+*j*, and, for all `uplo`, *A*(`ia`+*i*-1, `ja`+*i*-1) = `beta`, 1≤*i*≤min(`m`,`n`).

ia, *ja* (global) `INTEGER`.

The column and row indices in the distributed matrix *A* indicating the first row and column of the matrix sub(*A*), respectively.

desca (global and local)`INTEGER`.

Array of size *dlen_*. The array descriptor for the distributed matrix *A*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lasmsub

Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.

Syntax

```
call pslasmsub(a, desca, i, l, k, smlnum, buf, lwork)
call pdlasmsub(a, desca, i, l, k, smlnum, buf, lwork)
call pclasmsub(a, desca, i, l, k, smlnum, buf, lwork)
call pzlasmsub(a, desca, i, l, k, smlnum, buf, lwork)
```

Description

The `p?lasmsub`routine looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero. This routine performs a global maximum and must be called by all processes.

Input Parameters

a (local)

`REAL` for `pslasmsub`

`DOUBLE PRECISION` for `pdlasmsub`

`COMPLEX` for `pclasmsub`

DOUBLE COMPLEX for pzlasmsub

Array of size (*lld_a*,*LOCc*(*n_a*)).

On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.

desca (global and local) INTEGER.

Array of size *dlen_*. The array descriptor for the distributed matrix *A*.

i (global) INTEGER.

The global location of the bottom of the unreduced submatrix of *A*. Unchanged on exit.

l (global) INTEGER.

The global location of the top of the unreduced submatrix of *A*.

Unchanged on exit.

smlnum (global)

REAL for pslasmsub

DOUBLE PRECISION for pdlasmsub

REAL for pclasmsub

DOUBLE PRECISION for pzlasmsub

On entry, a "small number" for the given matrix. Unchanged on exit. The machine-dependent constants for the stopping criterion.

lwork (local) INTEGER.

This must be at least 2*ceil(ceil((*i*-1)/*mb_a*)/ lcm(*nprow*,*npcol*)). Here lcm is least common multiple and *nprowxnpcol* is the logical grid size.

Output Parameters

k (global) INTEGER.

On exit, this yields the bottom portion of the unreduced submatrix. This will satisfy: $l \leq k \leq i-1$.

buf (local).

REAL for pslasmsub

DOUBLE PRECISION for pdlasmsub

COMPLEX for pclasmsub

DOUBLE COMPLEX for pzlasmsub

Array of size *lwork*.

Application Notes

This routine parallelizes the code from ?lahqr that looks for a single small subdiagonal element.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lasrt

Sorts the numbers in an array and the corresponding vectors in increasing order.

Syntax

```
call pslasrt (id, n, d, q, iq, jq, descq, work, lwork, iwork, liwork, info )
call pdlasrt (id, n, d, q, iq, jq, descq, work, lwork, iwork, liwork, info )
```

Description

p?lasrt sorts the numbers in *d* and the corresponding vectors in *q* in increasing order.

Input Parameters

id (global)

CHARACTER*1.

= 'I': sort *d* in increasing order;

= 'D': sort *d* in decreasing order. (NOT IMPLEMENTED YET)

n (global)

INTEGER.

The number of columns to be operated on i.e the number of columns of the distributed submatrix sub(*Q*). *n* >= 0.

d (global)

REAL for pslasrt

DOUBLE PRECISION for pdlasrt

Array, size (*n*)

q (local)

REAL for pslasrt

DOUBLE PRECISION for pdlasrt

Pointer into the local memory to an array of size (*lld_q*,*LOCc*(*jq*+*n*-1)) .

This array contains the local pieces of the distributed matrix sub(*A*) to be copied from.

iq (global)

INTEGER.

The row index in the global array A indicating the first row of sub(*Q*).

jq (global)

INTEGER.

The column index in the global array A indicating the first column of sub(*Q*).

descq (global and local)

INTEGER.

Array of size *dlen_*.

The array descriptor for the distributed matrix *A*.

work (local)

`REAL` for `pslasrt`

`DOUBLE PRECISION` for `pdlasrt`

Array, size (*lwork*)

lwork (local)

INTEGER.

The size of the array *work*.

lwork = MAX(*n*, NP * (NB + NQ)), where NP = `numroc`(*n*, NB, MYROW, IAROW, NPROW), NQ = `numroc`(*n*, NB, MYCOL, DESCQ(*csrc_*), NPCOL).

`numroc` is a ScaLAPACK tool function.

iwork (local)

INTEGER.

Array, size (*liwork*)

liwork (local)

INTEGER.

The size of the array *iwork*.

liwork = *n* + 2*NB + 2*NPCOL

Output Parameters

d On exit, the numbers in *d* are sorted in increasing order.

info (global)

INTEGER.

= 0: successful exit

< 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?lassq

Updates a sum of squares represented in scaled form.

Syntax

```
call pslassq(n, x, ix, jx, descx, incx, scale, sumsq)
call pdlassq(n, x, ix, jx, descx, incx, scale, sumsq)
call pclassq(n, x, ix, jx, descx, incx, scale, sumsq)
call pzlassq(n, x, ix, jx, descx, incx, scale, sumsq)
```

Description

The p?lassqroutine returns the values *scl* and *smsq* such that

$scl^2 * smsq = x_1^2 + ... + x_n^2 + scale^2 * sumsq$,

where

x_i= sub(X) = X(*ix* + (*jx*-1)**m_x* + (*i* - 1)**incx*) for pslassq/pdlassq ,

x_i= sub(X) = abs(X(*ix* + (*jx*-1)**m_x* + (*i* - 1)**incx*) for pclassq/pzlassq.

For real routines pslassq/pdlassq the value of *sumsq* is assumed to be non-negative and *scl* returns the value

scl = max(*scale*, abs(x_i)).

For complex routines pclassq/pzlassq the value of *sumsq* is assumed to be at least unity and the value of *ssq* will then satisfy

$1.0 \le ssq \le sumsq + 2n$

Value *scale* is assumed to be non-negative and *scl* returns the value

$$scl = \max_i \left(scale, \mathbf{abs}\left(\mathbf{real}\left(x_i\right)\right), \mathbf{abs}\left(\mathbf{aimag}\left(x_i\right)\right)\right)$$

For all routines p?lassq values *scale* and *sumsq* must be supplied in *scale* and *sumsq* respectively, and *scale* and *sumsq* are overwritten by *scl* and *ssq* respectively.

All routines p?lassq make only one pass through the vector sub(X).

Input Parameters

n
(global) INTEGER.
The length of the distributed vector sub(x).

x
REAL for pslassq
DOUBLE PRECISION for pdlassq
COMPLEX for pclassq
COMPLEX*16 for pzlassq.
The vector for which a scaled sum of squares is computed:
x(*ix* + (*jx*-1)**m_x* + (*i* - 1)**incx*), 1 ≤ *i* ≤ *n*.

ix
(global) INTEGER.
The row index in the global matrix X indicating the first row of sub(X).

jx
(global) INTEGER.
The column index in the global matrix X indicating the first column of sub(X).

descx
(global and local) INTEGER array of size *dlen_*.
The array descriptor for the distributed matrix X.

incx
(global) INTEGER.

	The global increment for the elements of *X*. Only two values of *incx* are supported in this version, namely 1 and *m_x*. The argument *incx* must not equal zero.
scale	(local). `REAL` for `pslassq/pclassq` `DOUBLE PRECISION` for `pdlassq/pzlassq`. On entry, the value *scale* in the equation above.
sumsq	(local) `REAL` for `pslassq/pclassq` `DOUBLE PRECISION` for `pdlassq/pzlassq`. On entry, the value *sumsq* in the equation above.

Output Parameters

scale	(local). On exit, *scale* is overwritten with *scl* , the scaling factor for the sum of squares.
sumsq	(local). On exit, *sumsq* is overwritten with the value *smsq,* the basic sum of squares from which *scl* has been factored out.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

```
call pslaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pdlaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pclaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pzlaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
```

Description

The `p?laswp`routine performs a series of row or column interchanges on the distributed matrix `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`. One interchange is initiated for each of rows or columns *k1* through *k2* of sub(*A*). This routine assumes that the pivoting information has already been broadcast along the process row or column. Also note that this routine will only work for *k1-k2* being in the same *mb* (or *nb*) block. If you want to pivot a full matrix, use `p?lapiv`.

Input Parameters

direc	(global) `CHARACTER`. Specifies in which order the permutation is applied:

= 'F' - forward,

= 'B' - backward.

rowcol (global) CHARACTER.

Specifies if the rows or columns are permuted:

= 'R' - rows,

= 'C' - columns.

n (global) INTEGER.

If *rowcol*='R', the length of the rows of the distributed matrix *A*(*, *ja*:*ja*+*n*-1) to be permuted;

If *rowcol*='C', the length of the columns of the distributed matrix *A*(*ia*:*ia*+*n*-1 , *) to be permuted;

a (local)

REAL for pslaswp

DOUBLE PRECISION for pdlaswp

COMPLEX for pclaswp

COMPLEX*16 for pzlaswp.

Pointer into the local memory to an array of size (*lld_a*, *). On entry, this array contains the local pieces of the distributed matrix to which the row/columns interchanges will be applied.

ia (global) INTEGER.

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja (global) INTEGER.

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca (global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *A*.

k1 (global) INTEGER.

The first element of *ipiv* for which a row or column interchange will be done.

k2 (global) INTEGER.

The last element of *ipiv* for which a row or column interchange will be done.

ipiv (local)

INTEGER. Array of size *LOCr*(*m_a*)+*mb_a* for row pivoting and *LOCr*(*n_a*)+*nb_a* for column pivoting. This array is tied to the matrix *A*, *ipiv*(*k*)=*l* implies rows (or columns) *k* and *l* are to be interchanged.

Output Parameters

A (local)

REAL for pslaswp

DOUBLE PRECISION for pdlaswp

COMPLEX for pclaswp

COMPLEX*16 for pzlaswp.

On exit, the permuted distributed matrix.

p?latra

Computes the trace of a general square distributed matrix.

Syntax

```
val = pslatra(n, a, ia, ja, desca)
val = pdlatra(n, a, ia, ja, desca)
val = pclatra(n, a, ia, ja, desca)
val = pzlatra(n, a, ia, ja, desca)
```

Description

This function computes the trace of an *n*-by-*n* distributed matrix sub(*A*) denoting A(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1). The result is left on every process of the grid.

Input Parameters

n — (global) INTEGER.

The number of rows and columns to be operated on, that is, the order of the distributed matrix sub(*A*). *n* ≥0.

a — (local).

REAL for pslatra

DOUBLE PRECISION for pdlatra

COMPLEX for pclatra

COMPLEX*16 for pzlatra.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)) containing the local pieces of the distributed matrix, the trace of which is to be computed.

ia, *ja* — (global) INTEGER. The row and column indices respectively in the global matrix *A* indicating the first row and the first column of the matrix sub(*A*), respectively.

desca — (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

Output Parameters

val — The value returned by the function.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?latrd

Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.

Syntax

```
call pslatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pdlatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pclatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pzlatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
```

Description

The p?latrdroutine reduces *nb* rows and columns of a real symmetric or complex Hermitian matrix sub(*A*)= *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) to symmetric/complex tridiagonal form by an orthogonal/unitary similarity transformation *Q*'*sub(*A*)**Q*, and returns the matrices *V* and *W*, which are needed to apply the transformation to the unreduced part of sub(*A*).

If *uplo* = U, p?latrd reduces the last *nb* rows and columns of a matrix, of which the upper triangle is supplied;

if *uplo* = L, p?latrd reduces the first *nb* rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary routine called by p?sytrd/p?hetrd.

Input Parameters

uplo

(global) CHARACTER.

Specifies whether the upper or lower triangular part of the symmetric/ Hermitian matrix sub(*A*) is stored:

= 'U': Upper triangular

= L: Lower triangular.

n

(global) INTEGER.

The number of rows and columns to be operated on, that is, the order of the distributed matrix sub(*A*). *n* ≥ 0.

nb

(global) INTEGER.

The number of rows and columns to be reduced.

a

REAL for pslatrd

DOUBLE PRECISION for pdlatrd

COMPLEX for pclatrd

COMPLEX*16 for pzlatrd.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)).

On entry, this array contains the local pieces of the symmetric/Hermitian distributed matrix sub(*A*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*A*) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

ia (global) INTEGER.

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja (global) INTEGER.

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

iw (global) INTEGER.

The row index in the global matrix *W* indicating the first row of sub(*W*).

jw (global) INTEGER.

The column index in the global matrix *W* indicating the first column of sub(*W*).

descw (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *W*.

work (local)

REAL for pslatrd

DOUBLE PRECISION for pdlatrd

COMPLEX for pclatrd

COMPLEX*16 for pzlatrd.

Workspace array of size *nb_a*.

Output Parameters

a (local)

On exit, if *uplo* = 'U', the last *nb* columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of sub(*A*); the elements above the diagonal with the array *tau* represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors;

if *uplo* = 'L', the first *nb* columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of sub(*A*); the elements below the diagonal with the array *tau* represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors.

d (local)

REAL for pslatrd/pclatrd

DOUBLE PRECISION for pdlatrd/pzlatrd.

Array of size *LOCc(ja+n-1)*.

The diagonal elements of the tridiagonal matrix *T*: *d*(i) = *a*(i,i). *d* is tied to the distributed matrix *A*.

e

(local)

REAL for pslatrd/pclatrd

DOUBLE PRECISION for pdlatrd/pzlatrd.

Array of size *LOCc(ja+n-1)* if *uplo* = 'U', *LOCc(ja+n-2)* otherwise.

The off-diagonal elements of the tridiagonal matrix *T*:

e(*i*) = *a*(*i*, *i* + 1) if *uplo* = 'U',

e(*i*) = *a*(*i* + 1, *i*) if *uplo* = 'L'.

e is tied to the distributed matrix *A*.

tau

(local)

REAL for pslatrd

DOUBLE PRECISION for pdlatrd

COMPLEX for pclatrd

COMPLEX*16 for pzlatrd.

Array of size *LOCc(ja+n-1)*. This array contains the scalar factors of the elementary reflectors. *tau* is tied to the distributed matrix *A*.

w

(local)

REAL for pslatrd

DOUBLE PRECISION for pdlatrd

COMPLEX for pclatrd

COMPLEX*16 for pzlatrd.

Pointer into the local memory to an array of size *lld_w*by *nb_w*. This array contains the local pieces of the *n*-by-*nb_w* matrix *w* required to update the unreduced part of sub(*A*).

Application Notes

If *uplo* = 'U', the matrix *Q* is represented as a product of elementary reflectors

```
Q = H(n)*H(n-1)*...*H(n-nb+1)
```

Each *H*(*i*) has the form

```
H(i) = I - tau*v*v' ,
```

where *tau* is a real/complex scalar, and *v* is a real/complex vector with *v*(*i*:*n*) = 0 and *v*(*i*-1) = 1; *v*(1:*i*-1) is stored on exit in *A*(*ia*:*ia*+*i*-1, *ja*+*i*), and *tau* in *tau*(*ja*+*i*-1).

If *uplo* = L, the matrix *Q* is represented as a product of elementary reflectors

```
Q = H(1)*H(2)*...*H(nb)
```

Each *H*(i) has the form

```
H(i) = I - tau*v*v' ,
```

where *tau* is a real/complex scalar, and *v* is a real/complex vector with `v(1:i) = 0` and `v(i+1) = 1`; `v(i+2: n)` is stored on exit in `A(ia+i+1: ia+n-1, ja+i-1)`, and *tau* in `tau(ja+i-1)`.

The elements of the vectors *v* together form the *n*-by-*nb* matrix *V* which is needed, with *W*, to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank-2*k* update of the form:

`sub(A) := sub(A)-vw'-wv'`.

The contents of *a* on exit are illustrated by the following examples with

`n = 5` and `nb = 2`:

if *uplo*='U':

$$\begin{bmatrix} a & a & a & v_4 & v_5 \\ & a & a & v_4 & v_5 \\ & & a & 1 & v_5 \\ & & & d & 1 \\ & & & & d \end{bmatrix}$$

if *uplo*='L':

$$\begin{bmatrix} d & & & & \\ 1 & d & & & \\ v_1 & 1 & a & & \\ v_1 & v_2 & a & a & \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

where *d* denotes a diagonal element of the reduced matrix, *a* denotes an element of the original matrix that is unchanged, and v_i denotes an element of the vector defining *H*(i).

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?latrs

Solves a triangular system of equations with the scale factor set to prevent overflow.

Syntax

`call pslatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx, scale, cnorm, work)`

`call pdlatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx, scale, cnorm, work)`

`call pclatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx, scale, cnorm, work)`

`call pzlatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx, scale, cnorm, work)`

Description

The `p?latrs`routine solves a triangular system of equations $Ax = sb$, $A^Tx = sb$ or $A^Hx = sb$, where `s` is a scale factor set to prevent overflow. The description of the routine will be extended in the future releases.

Input Parameters

uplo CHARACTER*1.

Specifies whether the matrix *A* is upper or lower triangular.

= 'U': Upper triangular

= 'L': Lower triangular

trans

CHARACTER*1.

Specifies the operation applied to *Ax*.

= 'N': Solve $Ax = s*b$ (no transpose)

= 'T': Solve $A^Tx = s*b$ (transpose)

= 'C': Solve $A^Hx = s*b$ (conjugate transpose),

where *s* - is a scale factor

diag

CHARACTER*1.

Specifies whether or not the matrix *A* is unit triangular.

= 'N': Non-unit triangular

= 'U': Unit triangular

normin

CHARACTER*1.

Specifies whether *cnorm* has been set or not.

= 'Y': *cnorm* contains the column norms on entry;

= 'N': *cnorm* is not set on entry. On exit, the norms will be computed and stored in *cnorm*.

n

INTEGER.

The order of the matrix *A*. $n \geq 0$

a

REAL for pslatrs/pclatrs

DOUBLE PRECISION for pdlatrs/pzlatrs

Array of size *lda*by *n*. Contains the triangular matrix *A*.

If *uplo* = U, the leading *n*-by-*n* upper triangular part of the array *a* contains the upper triangular matrix, and the strictly lower triangular part of *a* is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of the array *a* contains the lower triangular matrix, and the strictly upper triangular part of *a* is not referenced.

If *diag* = 'U', the diagonal elements of *a* are also not referenced and are assumed to be 1.

ia, *ja*

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

x

REAL for pslatrs/pclatrs

DOUBLE PRECISION for pdlatrs/pzlatrs

	Array of size *n*. On entry, the right hand side *b* of the triangular system.
ix	(global)INTEGER.The row index in the global matrix *X* indicating the first row of sub(*x*).
jx	(global) INTEGER. The column index in the global matrix *X* indicating the first column of sub(*X*).
descx	(global and local) INTEGER. Array of size *dlen_*. The array descriptor for the distributed matrix *X*.
cnorm	REAL for pslatrs/pclatrs DOUBLE PRECISION for pdlatrs/pzlatrs. Array of size *n*. If *normin* = 'Y', *cnorm* is an input argument and *cnorm*(*j*) contains the norm of the off-diagonal part of the *j*-th column of *A*. If *trans* = 'N', *cnorm*(*j*) must be greater than or equal to the infinity-norm, and if *trans* = 'T' or 'C', *cnorm*(*j*) must be greater than or equal to the 1-norm.
work	(local). REAL for pslatrs DOUBLE PRECISION for pdlatrs COMPLEX for pclatrs COMPLEX*16 for pzlatrs. Temporary workspace.

Output Parameters

X	On exit, *x* is overwritten by the solution vector *x*.
scale	REAL for pslatrs/pclatrs DOUBLE PRECISION for pdlatrs/pzlatrs. Array of size *lda*by *n*. The scaling factor *s* for the triangular system as described above. If *scale* = 0, the matrix *A* is singular or badly scaled, and the vector *x* is an exact or approximate solution to *Ax* = 0.
cnorm	If *normin* = 'N', *cnorm* is an output argument and *cnorm*(*j*) returns the 1-norm of the off-diagonal part of the *j*-th column of *A*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?latrz

Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.

Syntax

```
call pslatrz(m, n, l, a, ia, ja, desca, tau, work)
```

```
call pdlatrz(m, n, l, a, ia, ja, desca, tau, work)
call pclatrz(m, n, l, a, ia, ja, desca, tau, work)
call pzlatrz(m, n, l, a, ia, ja, desca, tau, work)
```

Description

The p?latrzroutine reduces the *m*-by-*n* (*m* ≤ *n*) real/complex upper trapezoidal matrix sub(*A*) = [*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*m*-1)*A*(*ia*:*ia*+*m*-1, *ja*+*n*-*l*:*ja*+*n*-1)] to upper triangular form by means of orthogonal/unitary transformations.

The upper trapezoidal matrix sub(*A*) is factored as

sub(*A*) = (*R* 0)**Z*,

where *Z* is an *n*-by-*n* orthogonal/unitary matrix and *R* is an *m*-by-*m* upper triangular matrix.

Input Parameters

m

(global) INTEGER.

The number of rows in the distributed matrix sub(*A*). *m* ≥ 0.

n

(global) INTEGER.

The number of columns in the distributed matrix sub(*A*). *n* ≥ 0.

l

(global) INTEGER.

The number of columns of the distributed matrix sub(*A*) containing the meaningful part of the Householder reflectors. *l* > 0.

a

(local)

REAL for pslatrz

DOUBLE PRECISION for pdlatrz

COMPLEX for pclatrz

COMPLEX*16 for pzlatrz.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)). On entry, the local pieces of the *m*-by-*n* distributed matrix sub(*A*), which is to be factored.

ia

(global) INTEGER.

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja

(global) INTEGER.

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *A*.

work

(local)

REAL for pslatrz

DOUBLE PRECISION for pdlatrz

COMPLEX for pclatrz

COMPLEX*16 for pzlatrz.

Workspace array of size *lwork*.

lwork ≥ *nq*0 + max(1, *mp*0), where

iroff = mod(*ia*-1, *mb_a*),

icoff = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),

*mp*0 = numroc(*m*+*iroff*, *mb_a*, *myrow*, *iarow*, *nprow*),

*nq*0 = numroc(*n*+*icoff*, *nb_a*, *mycol*, *iacol*, *npcol*),

numroc, indxg2p, and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

a

On exit, the leading *m*-by-*m* upper triangular part of sub(*A*) contains the upper triangular matrix *R*, and elements *n*-*l*+1 to *n* of the first *m* rows of sub(*A*), with the array *tau*, represent the orthogonal/unitary matrix *Z* as a product of *m* elementary reflectors.

tau

(local)

REAL for pslatrz

DOUBLE PRECISION for pdlatrz

COMPLEX for pclatrz

COMPLEX*16 for pzlatrz.

Array of size*LOCr*(*ja*+*m*-1). This array contains the scalar factors of the elementary reflectors. *tau* is tied to the distributed matrix *A*.

Application Notes

The factorization is obtained by Householder's method. The *k*-th transformation matrix, *Z*(*k*), which is used (or, in case of complex routines, whose conjugate transpose is used) to introduce zeros into the (*m* - *k* + 1)-th row of sub(*A*), is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix},$$

where

$$T(k) = I - tau * u(k) * u(k)', \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

tau is a scalar and `z( k )` is an (*n*-*m*)-element vector. *tau* and `z( k )` are chosen to annihilate the elements of the *k*-th row of sub(*A*). The scalar *tau* is returned in the *k*-th element of *tau* and the vector `u( k )` in the *k*-th row of sub(*A*), such that the elements of `z(k )` are in *A*`( k, m + 1 ), ..., A( k, n )`. The elements of *R* are returned in the upper triangular part of sub(*A*).

Z is given by

```
Z =  Z(1)Z(2)...Z(m).
```

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lauu2

Computes the product `U*U'` or `L'*L`, where U and L are upper or lower triangular matrices (local unblocked algorithm).

Syntax

```
call pslauu2(uplo, n, a, ia, ja, desca)
call pdlauu2(uplo, n, a, ia, ja, desca)
call pclauu2(uplo, n, a, ia, ja, desca)
call pzlauu2(uplo, n, a, ia, ja, desca)
```

Description

The `p?lauu2`routine computes the product *U***U*' or *L*'**L*, where the triangular factor *U* or *L* is stored in the upper or lower triangular part of the distributed matrix

`sub(A)= A(ia:ia+n-1, ja:ja+n-1).`

If *uplo* = `'U'` or `'u'`, then the upper triangle of the result is stored, overwriting the factor *U* in sub(*A*).

If *uplo* = `'L'` or `'l'`, then the lower triangle of the result is stored, overwriting the factor *L* in sub(*A*).

This is the unblocked form of the algorithm, calling BLAS Level 2 Routines. No communication is performed by this routine, the matrix to operate on should be strictly local to one process.

Input Parameters

uplo

(global) `CHARACTER*1`.

Specifies whether the triangular factor stored in the *matrix* sub(*A*) is upper or lower triangular:

= `U`: upper triangular

= `L`: lower triangular.

n

(global) `INTEGER`.

The number of rows and columns to be operated on, that is, the order of the triangular factor *U* or *L*. $n \geq 0$.

a

(local)

`REAL` for `pslauu2`

`DOUBLE PRECISION` for `pdlauu2`

`COMPLEX` for `pclauu2`

COMPLEX*16 for pzlauu2.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)). On entry, the local pieces of the triangular factor *U* or *L*.

ia (global) INTEGER.

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja (global) INTEGER.

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

Output Parameters

a (local)

On exit, if *uplo* = 'U', the upper triangle of the distributed matrix sub(*A*) is overwritten with the upper triangle of the product *U***U*'; if *uplo* = 'L', the lower triangle of sub(*A*) is overwritten with the lower triangle of the product *L*'**L*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lauum

*Computes the product U*U' or L'*L, where U and L are upper or lower triangular matrices.*

Syntax

```
call pslauum(uplo, n, a, ia, ja, desca)
call pdlauum(uplo, n, a, ia, ja, desca)
call pclauum(uplo, n, a, ia, ja, desca)
call pzlauum(uplo, n, a, ia, ja, desca)
```

Description

The p?lauumroutine computes the product *U***U*' or *L*'**L*, where the triangular factor *U* or *L* is stored in the upper or lower triangular part of the matrix sub(*A*)= *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1).

If *uplo* = 'U' or 'u', then the upper triangle of the result is stored, overwriting the factor *U* in sub(*A*). If *uplo* = 'L' or 'l', then the lower triangle of the result is stored, overwriting the factor *L* in sub(*A*).

This is the blocked form of the algorithm, calling Level 3 PBLAS.

Input Parameters

uplo (global) CHARACTER*1.

Specifies whether the triangular factor stored in the matrix sub(*A*) is upper or lower triangular:

= 'U': upper triangular

= 'L': lower triangular.

n (global) INTEGER.

The number of rows and columns to be operated on, that is, the order of the triangular factor *U* or *L*. *n* ≥ 0.

a (local)

REAL for pslauum

DOUBLE PRECISION for pdlauum

COMPLEX for pclauum

COMPLEX*16 for pzlauum.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)). On entry, the local pieces of the triangular factor *U* or *L*.

ia (global) INTEGER.

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja (global) INTEGER.

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

Output Parameters

a (local)

On exit, if *uplo* = 'U', the upper triangle of the distributed matrix sub(*A*) is overwritten with the upper triangle of the product *U***U*' ; if *uplo* = 'L', the lower triangle of sub(*A*) is overwritten with the lower triangle of the product *L*'**L*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lawil

Forms the Wilkinson transform.

Syntax

```
call pslawil(ii, jj, m, a, desca, h44, h33, h43h34, v)
call pdlawil(ii, jj, m, a, desca, h44, h33, h43h34, v)
call pclawil(ii, jj, m, a, desca, h44, h33, h43h34, v)
call pzlawil(ii, jj, m, a, desca, h44, h33, h43h34, v)
```

Description

The p?lawilroutine gets the transform given by *h44*, *h33*, and *h43h34* into *v* starting at row *m*.

Input Parameters

ii

(global) INTEGER.

Number of the process row which owns the matrix element *A*(*m*+2, *m*+2).

jj

(global) INTEGER.

Number of the process column which owns the matrix element *A*(*m*+2, *m* +2).

m

(global) INTEGER.

On entry, the location from where the transform starts (row *m*). Unchanged on exit.

a

(local)

REAL for pslawil

DOUBLE PRECISION for pdlawil

COMPLEX for pclawil

DOUBLE COMPLEX for pzlawil

Array of size (*lld_a*,*LOCc*(*n_a*)).

On entry, the Hessenberg matrix. Unchanged on exit.

desca

(global and local) INTEGER

Array of size *dlen_*. The array descriptor for the distributed matrix *A*. Unchanged on exit.

h43h34

(global)

REAL for pslawil

DOUBLE PRECISION for pdlawil

COMPLEX for pclawil

DOUBLE COMPLEX for pzlawil

These three values are for the double shift *QR* iteration. Unchanged on exit.

Output Parameters

v

(global)

REAL for pslawil

DOUBLE PRECISION for pdlawil

COMPLEX for pclawil

DOUBLE COMPLEX for pzlawil

Array of size 3 that contains the transform on output.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?org2l/p?ung2l

Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by `p?geqlf` *(unblocked algorithm).*

Syntax

```
call psorg2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorg2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcung2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzung2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The `p?org2l/p?ung2l`routine generates an *m*-by-*n* real/complex distributed matrix *Q* denoting *A*`(ia:ia+m-1, ja:ja+n-1)` with orthonormal columns, which is defined as the last *n* columns of a product of *k* elementary reflectors of order *m*:

Q = *H*(*k*)*...*H*(2)*H*(1) as returned by `p?geqlf`.

Input Parameters

m

(global) `INTEGER`.

The number of rows in the distributed submatrix *Q*. $m \geq 0$.

n

(global) `INTEGER`.

The number of columns in the distributed submatrix *Q*. $m \geq n \geq 0$.

k

(global) `INTEGER`.

The number of elementary reflectors whose product defines the matrix *Q*. $n \geq k \geq 0$.

a

`REAL` for `psorg2l`

`DOUBLE PRECISION` for `pdorg2l`

`COMPLEX` for `pcung2l`

`COMPLEX*16` for `pzung2l`.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)).

On entry, the *j*-th column must contain the vector that defines the elementary reflector *H*`(j)`, $ja+n-k \leq j \leq ja+n-k$, as returned by `p?geqlf` in the *k* columns of its *distributed matrix* argument *A*`(ia:*,ja+n-k:ja+n-1)`.

ia

(global) `INTEGER`.

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja

(global) `INTEGER`.

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

tau (local)

REAL for psorg2l

DOUBLE PRECISION for pdorg2l

COMPLEX for pcung2l

COMPLEX*16 for pzung2l.

Array of size *LOCc*(*ja*+*n*-1).

tau(*j*) contains the scalar factor of the elementary reflector *H*(*j*), as returned by p?geqlf.

work (local)

REAL for psorg2l

DOUBLE PRECISION for pdorg2l

COMPLEX for pcung2l

COMPLEX*16 for pzung2l.

Workspace array of size *lwork*.

lwork (local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least *lwork* ≥ *mpa*0 + max(1, *nqa*0), where

iroffa = mod(*ia*-1, *mb_a*),

icoffa = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),

*mpa*0 = numroc(*m*+*iroffa*, *mb_a*, *myrow*, *iarow*, *nprow*),

*nqa*0 = numroc(*n*+*icoffa*, *nb_a*, *mycol*, *iacol*, *npcol*).

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a On exit, this array contains the local pieces of the *m*-by-*n* distributed matrix *Q*.

work On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local)INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then *info* = - (*i**100 +*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

p?org2r/p?ung2r

Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by p?geqrf *(unblocked algorithm).*

Syntax

```
call psorg2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorg2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcung2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzung2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The p?org2r/p?ung2rroutine generates an *m*-by-*n* real/complex matrix *Q* denoting *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1) with orthonormal columns, which is defined as the first *n* columns of a product of *k* elementary reflectors of order *m*:

Q = *H*(1)**H*(2)*...**H*(*k*)

as returned by p?geqrf.

Input Parameters

m (global) INTEGER.

The number of rows in the distributed submatrix *Q*.*m* ≥ 0.

n (global) INTEGER.

The number of columns in the distributed submatrix *Q*. *m* ≥ *n* ≥ 0.

k (global) INTEGER.

The number of elementary reflectors whose product defines the matrix *Q*. *n* ≥ *k* ≥ 0.

a REAL for psorg2r

DOUBLE PRECISION for pdorg2r

COMPLEX for pcung2r

COMPLEX*16 for pzung2r.

Pointer into the local memory to an array of size(*lld_a*, *LOCc*(*ja*+*n*-1))

On entry, the *j*-th column must contain the vector that defines the elementary reflector *H*(*j*), *ja* ≤ *j* ≤ *ja*+*k*−1, as returned by p?geqrf in the *k* columns of its *distributed matrix* argument *A*(*ia*:*,* *ja*:*ja*+*k*−1).

ia

(global) INTEGER.

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja

(global) INTEGER.

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *A*.

tau

(local)

REAL for psorg2r

DOUBLE PRECISION for pdorg2r

COMPLEX for pcung2r

COMPLEX*16 for pzung2r.

Array of size *LOCc*(*ja*+*k*-1).

tau(*j*) contains the scalar factor of the elementary reflector *H*(*j*), as returned by p?geqrf. This array is tied to the distributed matrix *A*.

work

(local)

REAL for psorg2r

DOUBLE PRECISION for pdorg2r

COMPLEX for pcung2r

COMPLEX*16 for pzung2r.

Workspace array of size *lwork*.

lwork

(local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least *lwork* ≥ *mpa*0 + max(1, *nqa*0), where

iroffa = mod(*ia*-1, *mb_a* , *icoffa* = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),

*mpa*0 = numroc(*m*+*iroffa*, *mb_a*, *myrow*, *iarow*, *nprow*),

*nqa*0 = numroc(*n*+*icoffa*, *nb_a*, *mycol*, *iacol*, *npcol*).

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a — On exit, this array contains the local pieces of the *m*-by-*n* distributed matrix *Q*.

work — On exit, *work*(1) returns the minimal and optimal *lwork*.

info — (local)INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then *info* = - (*i**100 +*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

p?orgl2/p?ungl2

Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by p?gelqf *(unblocked algorithm).*

Syntax

```
call psorgl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcungl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The p?orgl2/p?ungl2routine generates a *m*-by-*n* real/complex matrix *Q* denoting *A*(*ia*:*ia*+*m*-1, *ja*:*ja* +*n*-1) with orthonormal rows, which is defined as the first *m* rows of a product of *k* elementary reflectors of order *n*

Q = *H*(*k*)*...**H*(2)**H*(1) (for real flavors),

Q = $(H(k))^H$*...*$(H(2))^H$*$(H(1))^H$ (for complex flavors) as returned by p?gelqf.

Input Parameters

m — (global) INTEGER.

The number of rows in the distributed submatrix *Q*. *m* ≥ 0.

n — (global) INTEGER.

The number of columns in the distributed submatrix *Q*. *n* ≥ *m* ≥ 0.

k (global) INTEGER.

The number of elementary reflectors whose product defines the matrix *Q*. $m \geq k \geq 0$.

a REAL for psorgl2

DOUBLE PRECISION for pdorgl2

COMPLEX for pcungl2

COMPLEX*16 for pzungl2.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(ja+n-1)).

On entry, the *i*-th row must contain the vector that defines the elementary reflector *H*(*i*), $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the *k* rows of its *distributed matrix* argument *A*(*ia*:*ia*+*k*-1, *ja*:*).

ia (global) INTEGER.

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja (global) INTEGER.

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

tau (local)

REAL for psorgl2

DOUBLE PRECISION for pdorgl2

COMPLEX for pcungl2

COMPLEX*16 for pzungl2.

Array of size *LOCr*(ja+k-1). *tau*(*j*) contains the scalar factor of the elementary reflectors *H*(*j*), as returned by p?gelqf. This array is tied to the distributed matrix *A*.

WORK (local)

REAL for psorgl2

DOUBLE PRECISION for pdorgl2

COMPLEX for pcungl2

COMPLEX*16 for pzungl2.

Workspace array of size *lwork*.

lwork (local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least $lwork \geq nqa0 + \max(1, mpa0)$, where

iroffa = mod(*ia*-1, *mb_a*),

icoffa = mod(*ja*-1, *nb_a*),

iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),

iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),

mpa0 = numroc(*m*+*iroffa*, *mb_a*, *myrow*, *iarow*, *nprow*),

nqa0 = numroc(*n*+*icoffa*, *nb_a*, *mycol*, *iacol*, *npcol*).

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow,* and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = –1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a

On exit, this array contains the local pieces of the *m*-by-*n* distributed matrix *Q*.

work

On exit, *work*(1) returns the minimal and optimal *lwork*.

info

(local)INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then *info* = - (*i**100 +*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?orgr2/p?ungr2

Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by p?gerqf *(unblocked algorithm).*

Syntax

```
call psorgr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcungr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The p?orgr2/p?ungr2routine generates an *m*-by-*n* real/complex matrix *Q* denoting *A*(*ia*:*ia*+*m*–1, *ja*:*ja*+*n*–1) with orthonormal rows, which is defined as the last *m* rows of a product of *k* elementary reflectors of order *n*

Q = *H*(1)**H*(2)*...**H*(*k*) (for real flavors);

Q = $(H(1))^H$*$(H(2))^H$...*$(H(k))^H$ (for complex flavors) as returned by p?gerqf.

Input Parameters

m

(global) INTEGER.

The number of rows in the distributed submatrix *Q*. $m \geq 0$.

n

(global) INTEGER.

The number of columns in the distributed submatrix *Q*. $n \geq m \geq 0$.

k

(global) INTEGER.

The number of elementary reflectors whose product defines the matrix *Q*. $m \geq k \geq 0$.

a

REAL for psorgr2

DOUBLE PRECISION for pdorgr2

COMPLEX for pcungr2

COMPLEX*16 for pzungr2.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)).

On entry, the *i*-th row must contain the vector that defines the elementary reflector *H*(*i*), $ia+m-k \leq i \leq ia+m-1$, as returned by p?gerqf in the *k* rows of its *distributed matrix* argument *A*(*ia*+*m*-*k*:*ia*+*m*-1, *ja*:*).

ia

(global) INTEGER.

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja

(global) INTEGER.

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

tau

(local)

REAL for psorgr2

DOUBLE PRECISION for pdorgr2

COMPLEX for pcungr2

COMPLEX*16 for pzungr2.

Array of size *LOCr*(*ja*+*m*-1). *tau*(*j*) contains the scalar factor of the elementary reflectors *H*(*j*), as returned by p?gerqf. This array is tied to the distributed matrix *A*.

work

(local)

REAL for psorgr2

DOUBLE PRECISION for pdorgr2

COMPLEX for pcungr2

COMPLEX*16 for pzungr2.

Workspace array of size *lwork*.

lwork (local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least $lwork \geq nqa0 + \max(1, mpa0)$, where $iroffa = \mathrm{mod}(ia-1, mb\_a)$, $icoffa = \mathrm{mod}(ja-1, nb\_a)$,

$iarow = \mathrm{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$,

$iacol = \mathrm{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcol)$,

$mpa0 = \mathrm{numroc}(m+iroffa, mb\_a, myrow, iarow, nprow)$,

$nqa0 = \mathrm{numroc}(n+icoffa, nb\_a, mycol, iacol, npcol)$.

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a On exit, this array contains the local pieces of the *m*-by-*n* distributed matrix *Q*.

work On exit, $work(1)$ returns the minimal and optimal *lwork*.

info (local)INTEGER.

$= 0$: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then $info = -(i*100 + j)$,

if the *i*-th argument is a scalar and had an illegal value,

then $info = -i$.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?orm2l/p?unm2l

Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by p?geqlf *(unblocked algorithm).*

Syntax

call psorm2l(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pdorm2l(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pcunm2l(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pzunm2l(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

Description

The p?orm2l/p?unm2lroutine overwrites the general real/complex *m*-by-*n* distributed matrix sub(*C*)=*C*(*ic*:*ic*+*m*-1,*jc*:*jc*+*n*-1) with

*Q**sub(*C*) if *side* = 'L' and *trans* = 'N', or

Q^T*sub(*C*) / Q^H*sub(*C*) if *side* = 'L' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors), or

sub(*C*)**Q* if *side* = '*R*' and *trans* = 'N', or

sub(*C*)*Q^T / sub(*C*)*Q^H if *side* = 'R' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors).

where *Q* is a real orthogonal or complex unitary distributed matrix defined as the product of *k* elementary reflectors

Q = *H*(*k*)*...**H*(2)**H*(1) as returned by p?geqlf . *Q* is of order *m* if *side* = 'L' and of order *n* if *side* = 'R'.

Input Parameters

side
(global) CHARACTER.
= 'L': apply *Q* or Q^T for real flavors (Q^H for complex flavors) from the left,
= 'R': apply *Q* or Q^T for real flavors (Q^H for complex flavors) from the right.

trans
(global) CHARACTER.
= 'N': apply *Q* (no transpose)
= 'T': apply Q^T (transpose, for real flavors)
= 'C': apply Q^H (conjugate transpose, for complex flavors)

m
(global) INTEGER.
The number of rows in the distributed matrix sub(*C*). *m* ≥ 0.

n
(global) INTEGER.
The number of columns in the distributed matrix sub(*C*). *n* ≥ 0.

k
(global) INTEGER.
The number of elementary reflectors whose product defines the matrix *Q*.
If *side* = 'L', *m* ≥ *k* ≥ 0;
if *side* = 'R', *n* ≥ *k* ≥ 0.

a
(local)
REAL for psorm2l
DOUBLE PRECISION for pdorm2l
COMPLEX for pcunm2l
COMPLEX*16 for pzunm2l.
Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*k*-1)).

On entry, the *j*-th row must contain the vector that defines the elementary reflector *H*(*j*), $ja \le j \le ja+k-1$, as returned by p?geqlf in the *k* columns of its distributed matrix argument *A*(*ia*:*,*,*ja*:*ja*+*k*-1). The argument *A*(*ia*:*,*,*ja*:*ja*+*k*-1) is modified by the routine but restored on exit.

If *side* = 'L', lld_a ≥ max(1, *LOCr*(*ia*+*m*-1)),

if *side* = 'R', lld_a ≥ max(1, *LOCr*(*ia*+*n*-1)).

ia (global) INTEGER.

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja (global) INTEGER.

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

tau (local)

REAL for psorm2l

DOUBLE PRECISION for pdorm2l

COMPLEX for pcunm2l

COMPLEX*16 for pzunm2l.

Array of size *LOCc*(*ja*+*n*-1). *tau*(*j*) contains the scalar factor of the elementary reflector *H*(*j*), as returned by p?geqlf. This array is tied to the distributed matrix *A*.

c (local)

REAL for psorm2l

DOUBLE PRECISION for pdorm2l

COMPLEX for pcunm2l

COMPLEX*16 for pzunm2l.

Pointer into the local memory to an array of size (*lld_c*, *LOCc*(*jc* +*n*-1)).On entry, the local pieces of the distributed matrix sub (*C*).

ic (global) INTEGER.

The row index in the global matrix *C* indicating the first row of sub(*C*).

jc (global) INTEGER.

The column index in the global matrix *C* indicating the first column of sub(*C*).

descc (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work (local)

REAL for psorm2l

DOUBLE PRECISION for pdorm2l

COMPLEX for pcunm2l

COMPLEX*16 for pzunm2l.

Workspace array of size *lwork*.

On exit, *work*(1) returns the minimal and optimal *lwork*.

lwork (local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least

if *side* = 'L', *lwork* ≥ *mpc*0 + max(1, *nqc*0),

if *side* = 'R', *lwork* ≥ *nqc*0 + max(max(1, *mpc*0), numroc(numroc(*n* +*icoffc*, *nb_a*, 0, 0, *npcol*), *nb_a*, 0, 0, *lcmq*)),

where

lcmq = *lcm*/*npcol*,

lcm = iclm(*nprow*, *npcol*),

iroffc = mod(*ic*-1, *mb_c*),

icoffc = mod(*jc*-1, *nb_c*),

icrow = indxg2p(*ic*, *mb_c*, *myrow*, *rsrc_c*, *nprow*),

iccol = indxg2p(*jc*, *nb_c*, *mycol*, *csrc_c*, *npcol*),

Mqc0 = numroc(*m*+*icoffc*, *nb_c*, *mycol*, *icrow*, *nprow*),

Npc0 = numroc(*n*+*iroffc*, *mb_c*, *myrow*, *iccol*, *npcol*),

ilcm, indxg2p, and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c On exit, *c* is overwritten by *Q**sub(*C*), or Q^T*sub(*C*)/ Q^H*sub(*C*), or sub(*C*)**Q*, or sub(*C*)*Q^T / sub(*C*)*Q^H

work On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then *info* = - (*i**100 +*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

NOTE
The distributed submatrices *A*(*ia*:*, *ja*:*) and *C*(*ic*:*ic*+*m*-1,*jc*:*jc*+*n*-1) must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', (*mb_a*.eq.*mb_c* .AND. *iroffa*.eq.*iroffc* .AND. *iarow*.eq.*icrow*)

If *side* = 'R', (*mb_a*.eq.*nb_c* .AND. *iroffa*.eq.*iroffc*).

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?orm2r/p?unm2r

Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by p?geqrf *(unblocked algorithm).*

Syntax

call psorm2r(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pdorm2r(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pcunm2r(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pzunm2r(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

Description

The p?orm2r/p?unm2rroutine overwrites the general real/complex *m*-by-*n* distributed matrix sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1) with

*Q**sub(*C*) if *side* = 'L' and *trans* = 'N', or

Q^T*sub(*C*) / Q^H*sub(*C*) if *side* = 'L' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors), or

sub(*C*)**Q* if *side* = '*R*' and *trans* = 'N', or

sub(*C*)*Q^T / sub(*C*)*Q^H if *side* = 'R' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors).

where *Q* is a real orthogonal or complex unitary matrix defined as the product of *k* elementary reflectors

Q = H(*k*)*...**H*(2)**H*(1) as returned by p?geqrf . *Q* is of order *m* if *side* = 'L' and of order *n* if *side* = 'R'.

Input Parameters

side (global) CHARACTER.

= 'L': apply *Q* or Q^T for real flavors (Q^H for complex flavors) from the left,

= 'R': apply *Q* or Q^T for real flavors (Q^H for complex flavors) from the right.

trans (global) CHARACTER.

= 'N': apply Q (no transpose)

= 'T': apply Q^T (transpose, for real flavors)

= 'C': apply Q^H (conjugate transpose, for complex flavors)

m (global) INTEGER.

The number of rows in the distributed matrix sub(C). $m \geq 0$.

n (global) INTEGER.

The number of columns in the distributed matrix sub(C). $n \geq 0$.

k (global) INTEGER.

The number of elementary reflectors whose product defines the matrix Q.

If *side* = 'L', $m \geq k \geq 0$;

if *side* = 'R', $n \geq k \geq 0$.

a (local)

REAL for psorm2r

DOUBLE PRECISION for pdorm2r

COMPLEX for pcunm2r

COMPLEX*16 for pzunm2r.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*k*-1)).

On entry, the j-th column must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqrf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. The argument $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit.

If *side* = 'L', lld_a ≥ max(1, *LOCr*(*ia*+*m*-1)),

if *side* = 'R', lld_a ≥ max(1, *LOCr*(*ia*+*n*-1)).

ia (global) INTEGER.

The row index in the global matrix A indicating the first row of sub(A).

ja (global) INTEGER.

The column index in the global matrix A indicating the first column of sub(A).

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A.

tau (local)

REAL for psorm2r

DOUBLE PRECISION for pdorm2r

COMPLEX for pcunm2r

COMPLEX*16 for pzunm2r.

Array of size *LOCc*(*ja*+*k*-1). *tau*(*j*) contains the scalar factor of the elementary reflector *H*(*j*), as returned by p?geqrf. This array is tied to the distributed matrix *A*.

c

(local)

REAL for psorm2r

DOUBLE PRECISION for pdorm2r

COMPLEX for pcunm2r

COMPLEX*16 for pzunm2r.

Pointer into the local memory to an array of size (*lld_c*, *LOCc*(*jc*+*n*-1)).

On entry, the local pieces of the distributed matrix sub (*C*).

ic

(global) INTEGER.

The row index in the global matrix *C* indicating the first row of sub(*C*).

jc

(global) INTEGER.

The column index in the global matrix *C* indicating the first column of sub(*C*).

descc

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *C*.

work

(local)

REAL for psorm2r

DOUBLE PRECISION for pdorm2r

COMPLEX for pcunm2r

COMPLEX*16 for pzunm2r.

Workspace array of size *lwork*.

lwork

(local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least

if *side* = 'L', *lwork* ≥ *mpc*0 + max(1, *nqc*0),

if *side* = 'R', *lwork* ≥ *nqc*0 + max(max(1, *mpc*0), numroc(numroc(*n* +*icoffc*, *nb_a*, 0, 0, *npcol*), *nb_a*, 0, 0, *lcmq*)),

where

lcmq = *lcm*/*npcol* ,

lcm = *iclm*(*nprow*, *npcol*),

iroffc = mod(*ic*-*1*, *mb_c*),

icoffc = mod(*jc*-*1*, *nb_c*),

icrow = indxg2p(*ic*, *mb_c*, *myrow*, *rsrc_c*, *nprow*),

iccol = indxg2p(*jc*, *nb_c*, *mycol*, *csrc_c*, *npcol*),

Mqc0 = numroc(*m*+*icoffc*, *nb_c*, *mycol*, *icrow*, *nprow*),

Npc0 = numroc(*n*+*iroffc*, *mb_c*, *myrow*, *iccol*, *npcol*),

ilcm, indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = –1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c

On exit, *c* is overwritten by Q*sub(C), or Q^T*sub(C)/ Q^H*sub(C), or sub(C)*Q, or sub(C)*Q^T / sub(C)*Q^H

work

On exit, *work*(1) returns the minimal and optimal *lwork*.

info

(local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then *info* = - (*i**100 +*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

NOTE
The distributed submatrices *A*(*ia*:*, *ja*:*) and *C*(*ic*:*ic*+*m*–1, *jc*:*jc*+*n*–1) must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', (*mb_a*.eq.*mb_c* .AND. *iroffa*.eq.*iroffc* .AND. *iarow*.eq.*icrow*).

If *side* = 'R', (*mb_a*.eq.*nb_c* .AND. *iroffa*.eq.*iroffc*).

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?orml2/p?unml2

Multiplies a general matrix by the orthogonal/unitary matrix from an LQ factorization determined by p?gelqf *(unblocked algorithm).*

Syntax

call psorml2(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pdorml2(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pcunml2(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pzunml2(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

Description

The p?orml2/p?unml2routine overwrites the general real/complex *m*-by-*n* distributed matrix sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1) with

*Q**sub(*C*) if *side* = 'L' and *trans* = 'N', or

Q^T*sub(*C*) / Q^H*sub(*C*) if *side* = 'L' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors), or

sub(*C*)**Q* if *side* = 'R' and *trans* = 'N', or

sub(*C*)*Q^T / sub(*C*)*Q^H if *side* = 'R' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors).

where *Q* is a real orthogonal or complex unitary distributed matrix defined as the product of *k* elementary reflectors

Q = H(*k*)*...**H*(2)**H*(1) (for real flavors)

Q = (*H*(*k*))^H*...*(*H*(2))^H*(*H*(1))^H (for complex flavors)

as returned by p?gelqf . *Q* is of order *m* if *side* = 'L' and of order *n* if *side* = 'R'.

Input Parameters

side (global) CHARACTER.

= 'L': apply *Q* or Q^T for real flavors (Q^H for complex flavors) from the left,

= 'R': apply *Q* or Q^T for real flavors (Q^H for complex flavors) from the right.

trans (global) CHARACTER.

= 'N': apply *Q* (no transpose)

= 'T': apply Q^T (transpose, for real flavors)

= 'C': apply Q^H (conjugate transpose, for complex flavors)

m (global) INTEGER.

The number of rows in the distributed matrix sub(*C*). *m* ≥ 0.

n (global) INTEGER.

The number of columns in the distributed matrix sub(*C*). *n* ≥ 0.

k (global) INTEGER.

The number of elementary reflectors whose product defines the matrix *Q*.

If *side* = 'L', *m* ≥ *k* ≥ 0;

if *side* = 'R', *n* ≥ *k* ≥ 0.

a (local)

REAL for psorml2

DOUBLE PRECISION for pdorml2

COMPLEX for pcunml2

COMPLEX*16 for pzunml2.

Pointer into the local memory to an array of size

(*lld_a*, *LOCc*(*ja*+*m*-1)) if *side*='L',

(*lld_a*, *LOCc*(*ja*+*n*-1)) if *side*='R',

where *lld_a* ≥ max (1, *LOCr*(*ia*+*k*-1)).

On entry, the *i*-th row must contain the vector that defines the elementary reflector *H*(*i*), *ia* ≤ *i* ≤ *ia*+*k*-1, as returned by p?gelqf in the *k* rows of its distributed matrix argument *A*(*ia*:*ia*+*k*-1, *ja*:*). The argument *A*(*ia*:*ia*+*k*-1, *ja*:*) is modified by the routine but restored on exit.

ia (global) INTEGER.

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja (global) INTEGER.

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

tau (local)

REAL for psorml2

DOUBLE PRECISION for pdorml2

COMPLEX for pcunml2

COMPLEX*16 for pzunml2.

Array of size *LOCc*(*ia*+*k*-1). *tau*(*i*) contains the scalar factor of the elementary reflector *H*(*i*), as returned by p?gelqf. This array is tied to the distributed matrix *A*.

c (local)

REAL for psorml2

DOUBLE PRECISION for pdorml2

COMPLEX for pcunml2

COMPLEX*16 for pzunml2.

Pointer into the local memory to an array of size (*lld_c*, *LOCc*(*jc*+*n*-1)). On entry, the local pieces of the distributed matrix sub (*C*).

ic (global) INTEGER.

The row index in the global matrix *C* indicating the first row of sub(*C*).

jc (global) INTEGER.

The column index in the global matrix *C* indicating the first column of sub(*C*).

descc (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work (local)

REAL for psorml2

DOUBLE PRECISION for pdormlr2

COMPLEX for pcunmlr2

COMPLEX*16 for pzunmlr2.

Workspace array of size *lwork*.

lwork (local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least

if *side* = 'L', *lwork* ≥ *mqc0* + max(max(1, *npc0*), numroc(numroc(*m* +*icoffc*, *mb_a*, 0, 0, *nprow*), *mb_a*, 0, 0, *lcmp*)),

if *side* = 'R', *lwork* ≥ *npc0* + max(1, *mqc0*),

where

lcmp = *lcm* / *nprow*,

lcm = *iclm*(*nprow*, *npcol*),

iroffc = mod(*ic-1*, *mb_c*),

icoffc = mod(*jc-1*, *nb_c*),

icrow = indxg2p(*ic*, *mb_c*, *myrow*, *rsrc_c*, *nprow*),

iccol = indxg2p(*jc*, *nb_c*, *mycol*, *csrc_c*, *npcol*),

Mpc0 = numroc(*m*+*icoffc*, *mb_c*, *mycol*, *icrow*, *nprow*),

Nqc0 = numroc(*n*+*iroffc*, *nb_c*, *myrow*, *iccol*, *npcol*),

ilcm, indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c On exit, *c* is overwritten by Q*sub(C), or Q^T*sub(C)/ Q^H*sub(C), or sub(C)*Q, or sub(C)*Q^T / sub(C)*Q^H

work On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then *info* = - (*i**100 +*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

NOTE
The distributed submatrices *A*(*ia*:*, *ja*:*) and *C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1) must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', (*nb_a*.eq.*mb_c* .AND. *icoffa*.eq.*iroffc*)

If *side* = 'R', (*nb_a*.eq.*nb_c* .AND. *icoffa*.eq.*icoffc* .AND. *iacol*.eq.*iccol*).

p?ormr2/p?unmr2

Multiplies a general matrix by the orthogonal/unitary matrix from an RQ factorization determined by p?gerqf *(unblocked algorithm).*

Syntax

call psormr2(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pdormr2(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pcunmr2(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

call pzunmr2(*side*, *trans*, *m*, *n*, *k*, *a*, *ia*, *ja*, *desca*, *tau*, *c*, *ic*, *jc*, *descc*, *work*, *lwork*, *info*)

Description

The p?ormr2/p?unmr2routine overwrites the general real/complex *m*-by-*n* distributed matrix sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1) with

*Q**sub(*C*) if *side* = 'L' and *trans* = 'N', or

Q^T*sub(*C*) / Q^H*sub(*C*) if *side* = 'L' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors), or

sub(*C*)**Q* if *side* = 'R' and *trans* = 'N', or

sub(*C*)*Q^T / sub(*C*)*Q^H if *side* = 'R' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors).

where *Q* is a real orthogonal or complex unitary distributed matrix defined as the product of *k* elementary reflectors

Q = *H*(1)**H*(2)*...**H*(*k*) (for real flavors)

Q = $(H(1))^H$*$(H(2))^H$*...*$(H(k))^H$ (for complex flavors)

as returned by p?gerqf . *Q* is of order *m* if *side* = 'L' and of order *n* if *side* = 'R'.

Input Parameters

side (global) CHARACTER.

= 'L': apply *Q* or Q^T for real flavors (Q^H for complex flavors) from the left,

= 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.

trans

(global) CHARACTER.

= 'N': apply Q (no transpose)

= 'T': apply Q^T (transpose, for real flavors)

= 'C': apply Q^H(conjugate transpose, for complex flavors)

m

(global) INTEGER.

The number of rows in the distributed matrix sub(C). $m \geq 0$.

n

(global) INTEGER.

The number of columns in the distributed matrix sub(C). $n \geq 0$.

k

(global) INTEGER.

The number of elementary reflectors whose product defines the matrix Q.

If *side* = 'L', $m \geq k \geq 0$;

if *side* = 'R', $n \geq k \geq 0$.

a

(local)

REAL for psormr2

DOUBLE PRECISION for pdormr2

COMPLEX for pcunmr2

COMPLEX*16 for pzunmr2.

Pointer into the local memory to an array of size

(*lld_a*, *LOCc*(*ja*+*m*-1)) if *side*='L',

(*lld_a*, *LOCc*(*ja*+*n*-1)) if *side*='R',

where *lld_a* ≥ max (1, *LOCr*(*ia*+*k*-1)).

On entry, the *i*-th row must contain the vector that defines the elementary reflector *H*(*i*), *ia* ≤ *i* ≤ *ia*+*k*-1, as returned by p?gerqf in the *k* rows of its distributed matrix argument *A*(*ia*:*ia*+*k*-1, *ja*:*).

The argument *A*(*ia*:*ia*+*k*-1, *ja*:*) is modified by the routine but restored on exit.

ia

(global) INTEGER.

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja

(global) INTEGER.

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

tau

(local)

REAL for psormr2

DOUBLE PRECISION for pdormr2

COMPLEX for pcunmr2

COMPLEX*16 for pzunmr2.

Array of size *LOCc*(*ia*+*k*−1). *tau*(*j*) contains the scalar factor of the elementary reflector *H*(*j*), as returned by p?gerqf. This array is tied to the distributed matrix *A*.

c (local)

REAL for psormr2

DOUBLE PRECISION for pdormr2

COMPLEX for pcunmr2

COMPLEX*16 for pzunmr2.

Pointer into the local memory to an array of size (*lld_c*, *LOCc*(*jc*+*n*−1)). On entry, the local pieces of the distributed matrix sub (*C*).

ic (global) INTEGER.

The row index in the global matrix *C* indicating the first row of sub(*C*).

jc (global) INTEGER.

The column index in the global matrix *C* indicating the first column of sub(*C*).

descc (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work (local)

REAL for psormr2

DOUBLE PRECISION for pdormr2

COMPLEX for pcunmr2

COMPLEX*16 for pzunmr2.

Workspace array of size *lwork*.

lwork (local or global) INTEGER.

The size of the array *work*.

lwork is local input and must be at least

if *side* = 'L', *lwork* ≥ *mpc*0 + max(max(1, *nqc*0), numroc(numroc(*m* +*iroffc*, *mb_a*, 0, 0, *nprow*), *mb_a*, 0, 0, *lcmp*)),

if *side* = 'R', *lwork* ≥ *nqc*0 + max(1, *mpc*0),

where *lcmp* = *lcm*/*nprow*,

lcm = iclm(*nprow*, *npcol*),

iroffc = mod(*ic*-*1*, *mb_c*),

icoffc = mod(*jc*-*1*, *nb_c*),

icrow = indxg2p(*ic*, *mb_c*, *myrow*, *rsrc_c*, *nprow*),

iccol = indxg2p(*jc*, *nb_c*, *mycol*, *csrc_c*, *npcol*),

Mpc0 = numroc(*m*+*iroffc*, *mb_c*, *myrow*, *icrow*, *nprow*),

Nqc0 = numroc(*n*+*icoffc*, *nb_c*, *mycol*, *iccol*, *npcol*),

ilcm, indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = –1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c — On exit, *c* is overwritten by Q*sub(C), or Q^T*sub(C)/ Q^H*sub(C), or sub(C)*Q, or sub(C)*Q^T / sub(C)*Q^H

work — On exit, *work*(1) returns the minimal and optimal *lwork*.

info — (local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then *info* = - (*i**100 +*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

NOTE
The distributed submatrices *A*(*ia*:*, *ja*:*) and *C*(*ic*:*ic*+*m*-1,*jc*:*jc*+*n*-1) must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', (*nb_a*.eq.*mb_c* .AND. *icoffa*.eq.*iroffc*).

If *side* = 'R', (*nb_a*.eq.*nb_c* .AND. *icoffa*.eq.*icoffc* .AND. *iacol*.eq.*iccol*).

p?pbtrsv

Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a banded matrix computed by p?pbtrf.

Syntax

call pspbtrsv(*uplo*, *trans*, *n*, *bw*, *nrhs*, *a*, *ja*, *desca*, *b*, *ib*, *descb*, *af*, *laf*, *work*, *lwork*, *info*)

call pdpbtrsv(*uplo*, *trans*, *n*, *bw*, *nrhs*, *a*, *ja*, *desca*, *b*, *ib*, *descb*, *af*, *laf*, *work*, *lwork*, *info*)

call pcpbtrsv(*uplo*, *trans*, *n*, *bw*, *nrhs*, *a*, *ja*, *desca*, *b*, *ib*, *descb*, *af*, *laf*, *work*, *lwork*, *info*)

```
call pzpbtrsv(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork, info)
```

Description

The p?pbtrsvroutine solves a banded triangular system of linear equations

$A(1:n, ja:ja+n-1)*X = B(jb:jb+n-1, 1:nrhs)$

or

$A(1:n, ja:ja+n-1)^T*X = B(jb:jb+n-1, 1:nrhs)$ for real flavors,

$A(1:n, ja:ja+n-1)^H*X = B(jb:jb+n-1, 1:nrhs)$ for complex flavors,

where $A(1:n, ja:ja+n-1)$ is a banded triangular matrix factor produced by the Cholesky factorization code p?pbtrf and is stored in $A(1:n, ja:ja+n-1)$ and *af*. The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to *uplo*.

The routine p?pbtrf must be called first.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Input Parameters

uplo

(global) CHARACTER. Must be 'U' or 'L'.

If *uplo* = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored;

If *uplo* = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.

trans

(global) CHARACTER. Must be 'N' or 'T' or 'C'.

If *trans* = 'N', solve with $A(1:n, ja:ja+n-1)$;

If *trans* = 'T' or 'C' for real flavors, solve with $A(1:n, ja:ja+n-1)^T$.

If *trans* = 'C' for complex flavors, solve with conjugate transpose $(A(1:n, ja:ja+n-1)^H$.

n

(global) INTEGER.

The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$. $n \geq 0$.

bw

(global) INTEGER.

The number of subdiagonals in 'L' or 'U', $0 \leq bw \leq n-1$.

nrhs

(global) INTEGER.

The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$; $nrhs \geq 0$.

a

(local)

REAL for pspbtrsv

DOUBLE PRECISION for pdpbtrsv

COMPLEX for pcpbtrsv

COMPLEX*16 for pzpbtrsv.

Pointer into the local memory to an array with the first size *lld_a* ≥ (*bw* +1), stored in *desca*.

On entry, this array contains the local pieces of the *n*-by-*n* symmetric banded distributed Cholesky factor *L* or $L^T*A(1:n, ja:ja+n-1)$.

This local portion is stored in the packed banded format used in LAPACK. See the *Application Notes* below and the ScaLAPACK manual for more detail on the format of distributed matrices.

ja (global) INTEGER. The index in the global in the global matrix *A* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

If 1D type (*dtype_a* = 501), then *dlen*≥ 7;

If 2D type (*dtype_a* = 1), then *dlen*≥ 9.

Contains information on mapping of *A* to memory. (See ScaLAPACK manual for full description and options.)

b (local)

REAL for pspbtrsv

DOUBLE PRECISION for pdpbtrsv

COMPLEX for pcpbtrsv

COMPLEX*16 for pzpbtrsv.

Pointer into the local memory to an array of local lead size *lld_b*≥*nb*.

On entry, this array contains the local pieces of the right hand sides *B*(*jb*:*jb*+*n*-1, 1:*nrhs*).

ib (global) INTEGER. The row index in the global matrix *B* that points to the first row of the matrix to be operated on (which may be either all of *B* or a submatrix of *B*).

descb (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

If 1D type (*dtype_b* = 502), then *dlen*≥ 7;

If 2D type (*dtype_b* = 1), then *dlen*≥ 9.

Contains information on mapping of *B* to memory. Please, see ScaLAPACK manual for full description and options.

laf (local)

INTEGER. The size of user-input auxiliary fill-in space *af*. Must be *laf* ≥ (*nb*+2***bw*)***bw* . If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*(1).

work (local)

REAL for pspbtrsv

DOUBLE PRECISION for pdpbtrsv

COMPLEX for pcpbtrsv

COMPLEX*16 for pzpbtrsv.

The array *work* is a temporary workspace array of size *lwork*. This space may be overwritten in between calls to routines.

lwork (local or global) INTEGER. The size of the user-input workspace *work*, must be at least *lwork* ≥ *bw***nrhs*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

Output Parameters

af (local)

REAL for pspbtrsv

DOUBLE PRECISION for pdpbtrsv

COMPLEX for pcpbtrsv

COMPLEX*16 for pzpbtrsv.

The array *af* is of size *laf*. It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization routine p?pbtrf and is stored in *af*. If a linear system is to be solved using p?pbtrs after the factorization routine, *af* must not be altered after the factorization.

b On exit, this array contains the local piece of the solutions distributed matrix *X*.

work(1) On exit, *work*(1) contains the minimum value of *lwork*.

info (local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then *info* = - (*i**100 +*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

Application Notes

If the factorization routine and the solve routine are to be called separately to solve various sets of right-hand sides using the same coefficient matrix, the auxiliary space *af* must not be altered between calls to the factorization routine and the solve routine.

The best algorithm for solving banded and tridiagonal linear systems depends on a variety of parameters, especially the bandwidth. Currently, only algorithms designed for the case N/P>>*bw* are implemented. These algorithms go by many names, including Divide and Conquer, Partitioning, domain decomposition-type, etc.

The Divide and Conquer algorithm assumes the matrix is narrowly banded compared with the number of equations. In this situation, it is best to distribute the input matrix *A* one-dimensionally, with columns atomic and rows divided amongst the processes. The basic algorithm divides the banded matrix up into *P* pieces with one stored on each processor, and then proceeds in 2 phases for the factorization or 3 for the solution of a linear system.

1. **Local Phase**: The individual pieces are factored independently and in parallel. These factors are applied to the matrix creating fill-in, which is stored in a non-inspectable way in auxiliary space *af*. Mathematically, this is equivalent to reordering the matrix *A* as PAP^T and then factoring the principal leading submatrix of size equal to the sum of the sizes of the matrices factored on each processor. The factors of these submatrices overwrite the corresponding parts of *A* in memory.
2. **Reduced System Phase**: A small `(bw*(P-1))` system is formed representing interaction of the larger blocks and is stored (as are its factors) in the space `af`. A parallel Block Cyclic Reduction algorithm is used. For a linear system, a parallel front solve followed by an analogous backsolve, both using the structure of the factored matrix, are performed.
3. **Back Subsitution Phase**: For a linear system, a local backsubstitution is performed on each processor in parallel.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?pttrsv

Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a tridiagonal matrix computed by `p?pttrf` *.*

Syntax

```
call pspttrsv(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pdpttrsv(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pcpttrsv(uplo, trans, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pzpttrsv(uplo, trans, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
```

Description

The `p?pttrsv`routine solves a tridiagonal triangular system of linear equations

$A(1:n, ja:ja+n-1)*X = B(jb:jb+n-1, 1:nrhs)$

or

$A(1:n, ja:ja+n-1)^T*X = B(jb:jb+n-1, 1:nrhs)$ for real flavors,

$A(1:n, ja:ja+n-1)^H*X = B(jb:jb+n-1, 1:nrhs)$ for complex flavors,

where $A(1:n, ja:ja+n-1)$ is a tridiagonal triangular matrix factor produced by the Cholesky factorization code `p?pttrf` and is stored in $A(1:n, ja:ja+n-1)$ and `af`. The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to `uplo`.

The routine `p?pttrf` must be called first.

Input Parameters

`uplo` (global) `CHARACTER`. Must be `'U'` or `'L'`.

If `uplo = 'U'`, upper triangle of $A(1:n, ja:ja+n-1)$ is stored;

If *uplo* = 'L', lower triangle of *A*(1:*n*, *ja*:*ja*+*n*-1) is stored.

trans

(global) CHARACTER. Must be 'N' or 'C'.

If *trans* = 'N', solve with *A*(1:*n*, *ja*:*ja*+*n*-1);

If *trans* = 'C' (for complex flavors), solve with conjugate transpose $(A(1:n, ja:ja+n-1))^H$.

n

(global) INTEGER.

The number of rows and columns to be operated on, that is, the order of the distributed submatrix *A*(1:*n*, *ja*:*ja*+*n*-1). $n \geq 0$.

nrhs

(global) INTEGER.

The number of right hand sides; the number of columns of the distributed submatrix *B*(*jb*:*jb*+*n*-1, 1:*nrhs*); $nrhs \geq 0$.

d

(local)

REAL for pspttrsv

DOUBLE PRECISION for pdpttrsv

COMPLEX for pcpttrsv

COMPLEX*16 for pzpttrsv.

Pointer to the local part of the global vector storing the main diagonal of the matrix; must be of size ≥*nb_a*.

e

(local)

REAL for pspttrsv

DOUBLE PRECISION for pdpttrsv

COMPLEX for pcpttrsv

COMPLEX*16 for pzpttrsv.

Pointer to the local part of the global vector *du* storing the upper diagonal of the matrix; must be of size ≥*nb_a*. Globally, *du*(*n*) is not referenced, and *du* must be aligned with *d*.

ja

(global) INTEGER. The index in the global matrix *A* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

If 1D type (*dtype_a* = 501 or 502), then $dlen \geq 7$;

If 2D type (*dtype_a* = 1), then $dlen \geq 9$.

Contains information on mapping of *A* to memory. See ScaLAPACK manual for full description and options.

b

(local)

REAL for pspttrsv

DOUBLE PRECISION for pdpttrsv

COMPLEX for pcpttrsv

COMPLEX*16 for pzpttrsv.

Pointer into the local memory to an array of local lead size *lld_b* ≥ *nb*.

On entry, this array contains the local pieces of the right hand sides *B*(*jb*:*jb*+*n*-1, 1:*nrhs*).

ib (global) INTEGER. The row index in the global matrix *B* that points to the first row of the matrix to be operated on (which may be either all of *B* or a submatrix of *B*).

descb (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

If 1D type (*dtype_b* = 502), then *dlen* ≥ 7;

If 2D type (*dtype_b* = 1), then *dlen* ≥ 9.

Contains information on mapping of *B* to memory. See ScaLAPACK manual for full description and options.

laf (local)

INTEGER. The size of user-input auxiliary fill-in space *af*. Must be *laf* ≥ (*nb*+2**bw*)**bw*.

If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*(1).

work (local)

REAL for pspttrsv

DOUBLE PRECISION for pdpttrsv

COMPLEX for pcpttrsv

COMPLEX*16 for pzpttrsv.

The array *work* is a temporary workspace array of size *lwork*. This space may be overwritten in between calls to routines.

lwork (local or global) INTEGER. The size of the user-input workspace *work*, must be at least *lwork*≥(10+2*min(100, *nrhs*))***npcol*+4***nrhs*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

Output Parameters

d, *e* (local).

REAL for pspttrsv

DOUBLE PRECISION for pdpttrsv

COMPLEX for pcpttrsv

COMPLEX*16 for pzpttrsv.

On exit, these arrays contain information on the factors of the matrix.

af (local)

REAL for pspttrsv

DOUBLE PRECISION for pdpttrsv

COMPLEX for pcpttrsv

COMPLEX*16 for pzpttrsv.

The array *af* is of size *laf*. It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization routine p?pbtrf and is stored in *af*. If a linear system is to be solved using p?pttrs after the factorization routine, *af* must not be altered after the factorization.

b — On exit, this array contains the local piece of the solutions distributed matrix *X*.

work(1) — On exit, *work*(1) contains the minimum value of *lwork*.

info — (local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then *info* = - (*i**100 +*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

p?potf2

Computes the Cholesky factorization of a symmetric/ Hermitian positive definite matrix (local unblocked algorithm).

Syntax

```
call pspotf2(uplo, n, a, ia, ja, desca, info)
call pdpotf2(uplo, n, a, ia, ja, desca, info)
call pcpotf2(uplo, n, a, ia, ja, desca, info)
call pzpotf2(uplo, n, a, ia, ja, desca, info)
```

Description

The p?potf2routine computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite distributed matrix sub (*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1).

The factorization has the form

sub(*A*) = *U*'**U*, if *uplo* = 'U', or sub(*A*) = *L***L*', if *uplo* = 'L',

where *U* is an upper triangular matrix, *L* is lower triangular. *X*' denotes transpose (conjugate transpose) of *X*.

Input Parameters

uplo — (global) CHARACTER.

Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix *A* is stored.

= 'U': upper triangle of sub (*A*) is stored;

= 'L': lower triangle of sub (*A*) is stored.

n

(global) INTEGER.

The number of rows and columns to be operated on, that is, the order of the distributed matrix sub (*A*). *n* ≥ 0.

a

(local)

REAL for pspotf2

DOUBLE PRECISION for pdpotf2

COMPLEX for pcpotf2

COMPLEX*16 for pzpotf2.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)) containing the local pieces of the *n*-by-*n* symmetric distributed matrix sub(*A*) to be factored.

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*A*) contains the upper triangular matrix and the strictly lower triangular part of this matrix is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja*

(global) INTEGER.

The row and column indices in the global matrix *A* indicating the first row and the first column of the sub(*A*), respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

Output Parameters

a

(local)

On exit,

if *uplo* = 'U', the upper triangular part of the distributed matrix contains the Cholesky factor U;

if *uplo* = 'L', the lower triangular part of the distributed matrix contains the Cholesky factor L.

info

(local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then *info* = - (*i**100 +*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

> 0: if *info* = *k*, the leading minor of order *k* is not positive definite, and the factorization could not be completed.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?rot

Applies a planar rotation to two distributed vectors.

Syntax

```
call psrot( n, x, ix, jx, descx, incx, y, iy, jy, descy, incy, cs, sn, work, lwork, info )
call pdrot( n, x, ix, jx, descx, incx, y, iy, jy, descy, incy, cs, sn, work, lwork, info )
```

Description

p?rot applies a planar rotation defined by *cs* and *sn* to the two distributed vectors sub(*x*) and sub(*y*).

Input Parameters

n (global) INTEGER

The number of elements to operate on when applying the planar rotation to *x* and *y* (*n*≥0).

x REAL for psrot

DOUBLE PRECISION for pdrot

(local) array of size ((*jx*-1)*m_x + *ix* + (*n* - 1)*abs(*incx*))

This array contains the entries of the distributed vector sub(*x*).

ix (global) INTEGER

The global row index of the submatrix of the distributed matrix *x* to operate on. If *incx* = 1, then it is required that *ix* = *iy*. 1 ≤*ix*≤*m_x*.

jx (global) INTEGER

The global column index of the submatrix of the distributed matrix *x* to operate on. If *incx* = *m_x*, then it is required that *jx* = *jy*. 1 ≤*ix*≤*n_x*.

descx (global and local) INTEGER array of size 9

The array descriptor of the distributed matrix *x*.

incx (global) INTEGER

The global increment for the elements of *x*. Only two values of *incx* are supported in this version, namely 1 and *m_x*. Moreover, it must hold that *incx* = *m_x* if *incy* =*m_y* and that *incx* = 1 if *incy* = 1.

y REAL for psrot

DOUBLE PRECISION for pdrot

(local) array of size ((*jy*-1)*m_y + *iy* + (*n* - 1)*abs(*incy*))

This array contains the entries of the distributed vector sub(*y*).

iy

(global) INTEGER

The global row index of the submatrix of the distributed matrix *y* to operate on. If *incy* = 1, then it is required that *iy* = *ix*. 1 ≤*iy*≤*m_y*.

jy

(global) INTEGER

The global column index of the submatrix of the distributed matrix *y* to operate on. If *incy* = *m_x*, then it is required that *jy* = *jx*. 1 ≤*jy*≤*m_y*.

descy

(global and local) INTEGER array of size 9

The array descriptor of the distributed matrix *y*.

incy

(global) INTEGER

The global increment for the elements of *y*. Only two values of *incy* are supported in this version, namely 1 and *m_y*. Moreover, it must hold that *incy* = *m_y* if *incx* = *m_x* and that *incy* = 1 if *incx* = 1.

cs, *sn*

(global)

REAL for psrot

DOUBLE PRECISION for pdrot

The parameters defining the properties of the planar rotation. It must hold that 0 ≤*cs*,*sn*≤ 1 and that $sn^2 + cs^2 = 1$. The latter is hardly checked in finite precision arithmetics.

work

REAL for psrot

DOUBLE PRECISION for pdrot

(local workspace) array of size *lwork*

lwork

(local) INTEGER

The length of the workspace array *work*.

If *incx* = 1 and *incy* = 1, then *lwork* = 2**m_x*

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by pxerbla.

OUTPUT Parameters

x

y

work(1)

On exit, if *info* = 0, *work*(1) returns the optimal *lwork*

info

(global) INTEGER

= 0: successful exit

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?rscl

Multiplies a vector by the reciprocal of a real scalar.

Syntax

```
call psrscl(n, sa, sx, ix, jx, descx, incx)
call pdrscl(n, sa, sx, ix, jx, descx, incx)
call pcsrscl(n, sa, sx, ix, jx, descx, incx)
call pzdrscl(n, sa, sx, ix, jx, descx, incx)
```

Description

The p?rsclroutine multiplies an *n*-element real/complex vector sub(*X*) by the real scalar 1/*a*. This is done without overflow or underflow as long as the final result sub(*X*)/a does not overflow or underflow.

sub(*X*) denotes *X*(*ix*:*ix*+*n*-1, *jx*:*jx*), if *incx* = 1,

and *X*(*ix*:*ix*, *jx*:*jx*+*n*-1), if *incx* = *m_x*.

Input Parameters

n

(global) INTEGER.

The number of components of the distributed vector sub(*X*). *n* ≥ 0.

sa

REAL for psrscl/pcsrscl

DOUBLE PRECISION for pdrscl/pzdrscl.

The scalar *a* that is used to divide each component of the vector sub(*X*). This parameter must be ≥ 0.

sx

REAL forpsrscl

DOUBLE PRECISION for pdrscl

COMPLEX for pcsrscl

COMPLEX*16 for pzdrscl.

Array containing the local pieces of a distributed matrix of size of at least ((*jx*-1)**m_x* + *ix* + (*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*X*).

ix

(global) INTEGER.The row index of the submatrix of the distributed matrix *X* to operate on.

jx

(global) INTEGER.

The column index of the submatrix of the distributed matrix *X* to operate on.

descx

(global and local) INTEGER.

Array of size 9. The array descriptor for the distributed matrix *X*.

incx (global) INTEGER.

The increment for the elements of *X*. This version supports only two values of *incx*, namely 1 and *m_x*.

Output Parameters

sx On exit, the result *x*/*a*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?sygs2/p?hegs2

Reduces a symmetric/Hermitian positive-definite generalized eigenproblem to standard form, using the factorization results obtained from p?potrf *(local unblocked algorithm).*

Syntax

```
call pssygs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pdsygs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pchegs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pzhegs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
```

Description

The p?sygs2/p?hegs2routine reduces a real symmetric-definite or a complex Hermitian positive-definite generalized eigenproblem to standard form.

Here sub(*A*) denotes *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1), and sub(*B*) denotes *B*(*ib*:*ib*+*n*-1, *jb*:*jb*+*n*-1).

If *ibtype* = 1, the problem is

```
sub(A)*x = λ*sub(B)*x
```

and sub(*A*) is overwritten by

inv(U^T)*sub(*A*)*inv(*U*) or inv(*L*)*sub(*A*)*inv(L^T) - for real flavors, and

inv(U^H)*sub(*A*)*inv(*U*) or inv(*L*)*sub(*A*)*inv(L^H) - for complex flavors.

If *ibtype* = 2 or 3, the problem is

```
sub(A)*sub(B)x = λ*x or sub(B)*sub(A)x =λ*x
```

and sub(*A*) is overwritten by

*U*sub(*A*)*U^T or *L****T*sub(*A*)**L*- for real flavors and

*U*sub(*A*)*U^H or *L****H*sub(*A*)**L*- for complex flavors.

The matrix sub(*B*) must have been previously factorized as U^T*U or *L*L^T (for real flavors), or as U^H*U or *L*L^H (for complex flavors) by p?potrf.

Input Parameters

ibtype (global) INTEGER.

= 1:

compute inv(U^T)*sub(A)*inv(U), or inv(L)*sub(A)*inv(L^T) for real subroutines,

and inv(U^H)*sub(A)*inv(U), or inv(L)*sub(A)*inv(L^H) for complex subroutines;

= 2 or 3:

compute U*sub(A)*U^T, or L^T*sub(A)*L for real subroutines,

and U*sub(A)*U^H or L^H*sub(A)*L for complex subroutines.

uplo (global) CHARACTER

Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix sub(*A*) is stored, and how sub(*B*) is factorized.

= 'U': Upper triangular of sub(*A*) is stored and sub(*B*) is factorized as U^T*U (for real subroutines) or as U^H*U (for complex subroutines).

= 'L': Lower triangular of sub(*A*) is stored and sub(*B*) is factorized as $L*L^T$ (for real subroutines) or as $L*L^H$ (for complex subroutines)

n (global) INTEGER.

The order of the matrices sub(*A*) and sub(*B*). $n \geq 0$.

a (local)

REAL for pssygs2

DOUBLE PRECISION for pdsygs2

COMPLEX for pchegs2

COMPLEX*16 for pzhegs2.

Pointer into the local memory to an array of size (*lld_a*, *LOCc*(*ja*+*n*-1)).

On entry, this array contains the local pieces of the *n*-by-*n* symmetric/Hermitian distributed matrix sub(*A*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*A*) contains the upper triangular part of the matrix, and the strictly lower triangular part of sub(*A*) is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the matrix, and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja* (global) INTEGER.

The row and column indices in the global matrix *A* indicating the first row and the first column of the sub(*A*), respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

B (local)

REAL for pssygs2

DOUBLE PRECISION for pdsygs2

COMPLEX for pchegs2

COMPLEX*16 for pzhegs2.

Pointer into the local memory to an array of size (*lld_b*, *LOCc*(*jb*+*n*-1)).

On entry, this array contains the local pieces of the triangular factor from the Cholesky factorization of sub(*B*) as returned by p?potrf.

ib, *jb* (global) INTEGER.

The row and column indices in the global matrix *B* indicating the first row and the first column of the sub(*B*), respectively.

descb (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

Output Parameters

a (local)

On exit, if *info* = 0, the transformed matrix is stored in the same format as sub(*A*).

info INTEGER.

= 0: successful exit.

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then *info* = - (*i**100+ *j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?sytd2/p?hetd2

Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).

Syntax

```
call pssytd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pdsytd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pchetd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pzhetd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
```

Description

The p?sytd2/p?hetd2routine reduces a real symmetric/complex Hermitian matrix sub(*A*) to symmetric/ Hermitian tridiagonal form *T* by an orthogonal/unitary similarity transformation:

Q'*sub(*A*)**Q* = *T*, where sub(*A*) = *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1).

Input Parameters

uplo

(global) CHARACTER.

Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix sub(*A*) is stored:

= 'U': upper triangular

= 'L': lower triangular

n

(global) INTEGER.

The number of rows and columns to be operated on, that is, the order of the distributed matrix sub(*A*). $n \geq 0$.

a

(local)

REAL for pssytd2

DOUBLE PRECISION for pdsytd2

COMPLEX for pchetd2

COMPLEX*16 for pzhetd2.

Pointer into the local memory to an array of size $(lld\_a, LOC_c(ja+n-1))$.

On entry, this array contains the local pieces of the *n*-by-*n* symmetric/Hermitian distributed matrix sub(*A*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*A*) contains the upper triangular part of the matrix, and the strictly lower triangular part of sub(*A*) is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the matrix, and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja*

(global) INTEGER.

The row and column indices in the global matrix *A* indicating the first row and the first column of the sub(*A*), respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

work

(local)

REAL for pssytd2

DOUBLE PRECISION for pdsytd2

COMPLEX for pchetd2

COMPLEX*16 for pzhetd2.

The array *work* is a temporary workspace array of size *lwork*.

Output Parameters

a

On exit, if *uplo* = 'U', the diagonal and first superdiagonal of sub(*A*) are overwritten by the corresponding elements of the tridiagonal matrix *T*, and the elements above the first superdiagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors;

if *uplo* = 'L', the diagonal and first subdiagonal of *A* are overwritten by the corresponding elements of the tridiagonal matrix *T*, and the elements below the first subdiagonal, with the array *tau,* represent the orthogonal/ unitary matrix *Q* as a product of elementary reflectors. See the *Application Notes* below.

d

(local)

REAL for pssytd2/pchetd2

DOUBLE PRECISION for pdsytd2/pzhetd2.

Array of size*LOCc*(*ja*+*n*-1). The diagonal elements of the tridiagonal matrix *T*:

d(i) = *a*(i,i); *d* is tied to the distributed matrix *A*.

e

(local)

REAL for pssytd2/pchetd2

DOUBLE PRECISION for pdsytd2/pzhetd2.

Array of size *LOCc*(*ja*+*n*-1),

if *uplo* = 'U', *LOCc*(*ja*+*n*-2) otherwise.

The off-diagonal elements of the tridiagonal matrix *T*:

e(i) = *a*(i,i+1) if *uplo* = 'U',

e(i) = *a*(i+1,i) if *uplo* = 'L'.

e is tied to the distributed matrix *A*.

tau

(local)

REAL for pssytd2

DOUBLE PRECISION for pdsytd2

COMPLEX for pchetd2

COMPLEX*16 for pzhetd2.

Array of size *LOCc*(*ja*+*n*-1).

The scalar factors of the elementary reflectors. *tau* is tied to the distributed matrix *A*.

work(1)

On exit, *work*(1) returns the minimal and optimal value of *lwork*.

lwork

(local or global) INTEGER.

The size of the workspace array *work*.

lwork is local input and must be at least *lwork* ≥ 3*n*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

info

(local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then *info* = -(*i**100+*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

Application Notes

If *uplo* = 'U', the matrix *Q* is represented as a product of elementary reflectors

Q = *H*(*n*-1)*...**H*(2)**H*(1)

Each *H*(i) has the form

H(i) = *I* - *tau***v***v*',

where *tau* is a real/complex scalar, and *v* is a real/complex vector with *v*(*i*+1:*n*) = 0 and *v*(*i*) = 1; *v*(1:*i*-1) is stored on exit in *A*(*ia*:*ia*+*i*-2, *ja*+*i*), and *tau* in *tau*(*ja*+*i*-1).

If *uplo* = 'L', the matrix *Q* is represented as a product of elementary reflectors

Q = *H*(1)**H*(2)*...**H*(*n*-1).

Each *H*(i) has the form

H(i) = *I* - *tau***v***v*' ,

where *tau* is a real/complex scalar, and *v* is a real/complex vector with *v*(1:*i*) = 0 and *v*(*i*+1) = 1; *v*(*i*+2:*n*) is stored on exit in *A*(*ia*+*i*+1:*ia*+*n*-1, *ja*+*i*-1), and *tau* in *tau*(*ja*+*i*-1).

The contents of sub (*A*) on exit are illustrated by the following examples with *n* = 5:

if *uplo*='U':

$$\begin{bmatrix} d & e & v_2 & v_3 & v_4 \\ & d & e & v_3 & v_4 \\ & & d & e & v_4 \\ & & & d & e \\ & & & & d \end{bmatrix}$$

if *uplo*='L':

$$\begin{bmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v_2 & e & d & \\ v1 & v_2 & v_3 & e & d \end{bmatrix}$$

where *d* and *e* denotes diagonal and off-diagonal elements of *T*, and v_i denotes an element of the vector defining *H*(i).

NOTE

The distributed matrix sub(*A*) must verify some alignment properties, namely the following expression should be true:

(*mb_a*.eq.*nb_a* .AND. *iroffa*.eq.*icoffa*)with *iroffa* = mod(*ia* - 1, *mb_a*) and *icoffa* = mod(*ja* -1, *nb_a*).

p?trord

Reorders the Schur factorization of a general matrix.

Syntax

```
call pstrord( compq, select, para, n, t, it, jt, desct, q, iq, jq, descq, wr, wi, m,
work, lwork, iwork, liwork, info )
```

```
call pdtrord( compq, select, para, n, t, it, jt, desct, q, iq, jq, descq, wr, wi, m,
work, lwork, iwork, liwork, info )
```

Description

`p?trord` reorders the real Schur factorization of a real matrix $A = Q*T*Q^T$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

T must be in Schur form (as returned by `p?lahqr`), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks.

This subroutine uses a delay and accumulate procedure for performing the off-diagonal updates.

Input Parameters

compq

(global) `CHARACTER*1`

= 'V': update the matrix *q* of Schur vectors;

= 'N': do not update *q*.

select

(global) `INTEGER` array of size *n*

select specifies the eigenvalues in the selected cluster. To select a real eigenvalue *w*(*j*), *select*(*j*) must be set to 1. To select a complex conjugate pair of eigenvalues *w*(*j*) and *w*(*j*+1), corresponding to a 2-by-2 diagonal block, either *select*(*j*) or *select*(*j*+1) or both must be set to 1; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

para

(global) `INTEGER*6`

Block parameters:

para(1)	maximum number of concurrent computational windows allowed in the algorithm; 0 < *para*(1)≤ min(*nprow*, *npcol*) must hold;
para(2)	number of eigenvalues in each window; 0 < *para*(2) < *para*(3) must hold;
para(3)	window size; *para*(2) < *para*(3) < *mb_t* must hold;
para(4)	minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; 0 ≤*para*(4)≤ 100 must hold;

	para(5)	width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; 0 < *para*(5)≤*mb_t* must hold.
	para(6)	the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size; 0 < *para*(6)≤*para*(2) must hold.

n (global) INTEGER

The order of the globally distributed matrix *t*. *n*≥ 0.

t REAL for pstrord

DOUBLE PRECISION for pdtrord

(local) array of size (*lld_t*,*LOC*$_c$(*n*)).

The local pieces of the global distributed upper quasi-triangular matrix *T*, in Schur form.

it, *jt* (global) INTEGER

The row and column index in the global matrix *T* indicating the first column of *T*. *it* = *jt* = 1 must hold (see Application Notes).

desct (global and local) INTEGER array of size *dlen_*.

The array descriptor for the global distributed matrix *T*.

q REAL for pstrord

DOUBLE PRECISION for pdtrord

(local) array of size (*lld_q*,*LOC*$_c$(*n*)).

On entry, if *compq* = 'V', the local pieces of the global distributed matrix *Q* of Schur vectors.

If *compq* = 'N', *q* is not referenced.

iq, *jq* (global) INTEGER

The column index in the global matrix *Q* indicating the first column of *Q*. *iq* = *jq* = 1 must hold (see Application Notes).

descq (global and local) INTEGER array of size *dlen_*.

The array descriptor for the global distributed matrix *Q*.

work REAL for pstrord

DOUBLE PRECISION for pdtrord

(local workspace) array of size *lwork*

lwork (local) INTEGER

The size of the array *work*.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by pxerbla.

iwork (local workspace) INTEGER array of size *liwork*

liwork (local) INTEGER

The size of the array *iwork*.

If *liwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued by pxerbla

OUTPUT Parameters

select (global) INTEGER array of size *n*

The (partial) reordering is displayed.

t On exit, *t* is overwritten by the local pieces of the reordered matrix *T*, again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks.

q On exit, if *compq* = 'V', *q* has been postmultiplied by the global orthogonal transformation matrix which reorders *t*; the leading *m* columns of *q* form an orthonormal basis for the specified invariant subspace.

If *compq* = 'N', *q* is not referenced.

wr, *wi* REAL for pstrord

DOUBLE PRECISION for pdtrord

(global) array of size *n*

The real and imaginary parts, respectively, of the reordered eigenvalues of the matrix *T*. The eigenvalues are in principle stored in the same order as on the diagonal of *T*, with *wr*(*i*) = *t*(*i*,*i*) and, if *t*(*i*:*i*+1,*i*:*i*+1) is a 2-by-2 diagonal block, *wi*(*i*) > 0 and *wi*(*i*+1) = -*wi*(*i*).

Note also that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

m (global) INTEGER

The size of the specified invariant subspace.

$0 \leq m \leq n$.

work(1) On exit, if *info* = 0, *work*(1) returns the optimal *lwork*.

iwork(1) On exit, if *info* = 0, *iwork*(1) returns the optimal *liwork*.

info (global) INTEGER

= 0: successful exit

< 0: if *info* = -*i*, the *i*-th argument had an illegal value. If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**1000+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

> 0: here we have several possibilities

- Reordering of *t* failed because some eigenvalues are too close to separate (the problem is very ill-conditioned);

  t may have been partially reordered, and *wr* and *wi* contain the eigenvalues in the same order as in *t*.

  On exit, *info* = {the index of *t* where the swap failed}.
- A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block.

  On exit, *info* = {the index of *t* where the swap failed}.
- If *info* = *n*+1, there is no valid BLACS context (see the BLACS documentation for details).

Application Notes

The following alignment requirements must hold:

- *mb_t* = *nb_t* = *mb_q* = *nb_q*
- *rsrc_t* = *rsrc_q*
- *csrc_t* = *csrc_q*

All matrices must be blocked by a block factor larger than or equal to two (3). This is to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of *t* and *q*, i.e., *it* = *jt* = *iq* = *jq* = 1 must hold. This is however no limitation since p?lahqr does not compute Schur forms of submatrices anyway.

Parallel execution recommendations:

- Use a square grid, if possible, for maximum performance. The block parameters in *para* should be kept well below the data distribution block size.
- In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?trsen

Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers and invariant subspace for the selected cluster of eigenvalues.

Syntax

```
call pstrsen( job, compq, select, para, n, t, it, jt, desct, q, iq, jq, descq, wr, wi, m, s, sep, work, lwork, iwork, liwork, info )
```

```
call pdtrsen( job, compq, select, para, n, t, it, jt, desct, q, iq, jq, descq, wr, wi, m, s, sep, work, lwork, iwork, liwork, info )
```

Description

p?trsen reorders the real Schur factorization of a real matrix $A = Q*T*Q^T$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace. The reordering is performed by p?trord.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

T must be in Schur form (as returned by p?lahqr), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks.

Input Parameters

job

(global) CHARACTER*1

Specifies whether condition numbers are required for the cluster of eigenvalues (*s*) or the invariant subspace (*sep*):

= 'N': no condition numbers are required;

= 'E': only the condition number for the cluster of eigenvalues is computed (*s*);

= 'V': only the condition number for the invariant subspace is computed (*sep*);

= 'B': condition numbers for both the cluster and the invariant subspace are computed (*s* and *sep*).

compq

(global) CHARACTER*1

= 'V': update the matrix *q* of Schur vectors;

= 'N': do not update *q*.

select

(global) LOGICAL array of size *n*

select specifies the eigenvalues in the selected cluster. To select a real eigenvalue *w*(*j*), *select*(*j*) must be set to .TRUE.. To select a complex conjugate pair of eigenvalues *w*(*j*) and *w*(*j*+1), corresponding to a 2-by-2 diagonal block, either *select*(*j*) or *select*(*j*+1) or both must be set to .TRUE.; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

para

(global) INTEGER*6

Block parameters:

para(1) maximum number of concurrent computational windows allowed in the algorithm; 0 < *para*(1)≤ min(NPROW,NPCOL) must hold;

para(2)	number of eigenvalues in each window; 0 < *para*(2) < *para*(3) must hold;
para(3)	window size; *para*(2) < *para*(3) < *mb_t* must hold;
para(4)	minimal percentage of flops required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; 0 ≤*para*(4)≤ 100 must hold;
para(5)	width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; 0 < *para*(5)≤*mb_t* must hold.
para(6)	the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size 0 < *para*(6)≤*para*(2) must hold;

n

(global) INTEGER

The order of the globally distributed matrix *t*. *n*≥ 0.

t

REAL for pstrsen

DOUBLE PRECISION for pdtrsen

(local) array of size (*lld_t*,*LOC*$_c$(*n*)).

The local pieces of the global distributed upper quasi-triangular matrix *T*, in Schur form.

it, *jt*

(global) INTEGER

The row and column index in the global matrix *T* indicating the first column of *T*. *it* = *jt* = 1 must hold (see Application Notes).

desct

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the global distributed matrix *T*.

q

REAL for pstrsen

DOUBLE PRECISION for pdtrsen

(local) array of size (*lld_q*,*LOC*$_c$(*n*)).

On entry, if *compq* = 'V', the local pieces of the global distributed matrix *Q* of Schur vectors.

If *compq* = 'N', *q* is not referenced.

iq, *jq*

(global) INTEGER

The column index in the global matrix *Q* indicating the first column of *Q*. *iq* = *jq* = 1 must hold (see Application Notes).

descq

(global and local) INTEGER array of size *dlen_*.

The array descriptor for the global distributed matrix *Q*.

work

REAL for pstrsen

DOUBLE PRECISION for pdtrsen

(local workspace) array of size *lwork*

lwork

(local) INTEGER

The size of the array *work*.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by pxerbla.

iwork

(local workspace) INTEGER array of size *liwork*

liwork

(local) INTEGER

The size of the array *iwork*.

If *liwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued by pxerbla.

OUTPUT Parameters

t

t is overwritten by the local pieces of the reordered matrix *T*, again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks.

q

On exit, if *compq* = 'V', *q* has been postmultiplied by the global orthogonal transformation matrix which reorders *t*; the leading *m* columns of *q* form an orthonormal basis for the specified invariant subspace.

If *compq* = 'N', *q* is not referenced.

wr, *wi*

REAL for pstrsen

DOUBLE PRECISION for pdtrsen

(global) array of size *n*

The real and imaginary parts, respectively, of the reordered eigenvalues of the matrix *T*. The eigenvalues are in principle stored in the same order as on the diagonal of *T*, with *wr*(*i*) = *t*(*i*,*i*) and, if *t*(*i*:*i*+1,*i*:*i*+1) is a 2-by-2 diagonal block, *wi*(*i*) > 0 and *wi*(*i*+1) = -*wi*(*i*).

Note also that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

m

(global) INTEGER

The size of the specified invariant subspace. 0 ≤*m*≤*n*.

s

REAL for pstrsen

DOUBLE PRECISION for pdtrsen

(global)

If *job* = 'E' or 'B', *s* is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. *s* cannot underestimate the true reciprocal condition number by more than a factor of sqrt(*n*). If *m* = 0 or *n*, *s* = 1.

If *job* = 'N' or 'V', *s* is not referenced.

sep

`REAL` for `pstrsen`

`DOUBLE PRECISION` for `pdtrsen`

(global)

If *job* = 'V' or 'B', *sep* is the estimated reciprocal condition number of the specified invariant subspace. If

m = 0 or *n*, *sep* = norm(*t*).

If *job* = 'N' or 'E', *sep* is not referenced.

work(1)

On exit, if *info* = 0, *work*(1) returns the optimal *lwork*.

iwork(1)

On exit, if *info* = 0, *iwork*(1) returns the optimal *liwork*.

info

(global) `INTEGER`

= 0: successful exit

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**1000+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

> 0: here we have several possibilities

- Reordering of *t* failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); *t* may have been partially reordered, and *wr* and *wi* contain the eigenvalues in the same order as in *t*.

  On exit, *info* = {the index of *t* where the swap failed}.
- A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block.

  On exit, *info* = {the index of *t* where the swap failed}.
- If *info* = *n*+1, there is no valid BLACS context (see the BLACS documentation for details).

Application Notes

The following alignment requirements must hold:

- *mb_t* = *nb_t* = *mb_q* = *nb_q*
- *rsrc_t* = *rsrc_q*
- *csrc_t* = *csrc_q*

All matrices must be blocked by a block factor larger than or equal to two (3). This to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of *t* and *q*, i.e., *it* = *jt* = *iq* = *jq* = 1 must hold. This is however no limitation since `p?lahqr` does not compute Schur forms of submatrices anyway.

For parallel execution, use a square grid, if possible, for maximum performance. The block parameters in *para* should be kept well below the data distribution block size.

In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

p?trti2

Computes the inverse of a triangular matrix (local unblocked algorithm).

Syntax

```
call pstrti2(uplo, diag, n, a, ia, ja, desca, info)
call pdtrti2(uplo, diag, n, a, ia, ja, desca, info)
call pctrti2(uplo, diag, n, a, ia, ja, desca, info)
call pztrti2(uplo, diag, n, a, ia, ja, desca, info)
```

Description

The p?trti2routine computes the inverse of a real/complex upper or lower triangular block matrix sub (*A*) = *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1).

This matrix should be contained in one and only one process memory space (local operation).

Input Parameters

uplo

(global) CHARACTER*1.

Specifies whether the matrix sub (*A*) is upper or lower triangular.

= 'U': sub (*A*) is upper triangular

= 'L': sub (*A*) is lower triangular.

diag

(global) CHARACTER*1.

Specifies whether or not the matrix *A* is unit triangular.

= 'N': sub (*A*) is non-unit triangular

= 'U': sub (*A*) is unit triangular.

n

(global) INTEGER.

The number of rows and columns to be operated on, i.e., the order of the distributed submatrix sub(*A*). $n \geq 0$.

a

(local)

REAL for pstrti2

DOUBLE PRECISION for pdtrti2

COMPLEX for pctrti2

COMPLEX*16 for pztrti2.

Pointer into the local memory to an array, size (*lld_a*, *LOCc*(*ja*+*n*-1)).

On entry, this array contains the local pieces of the triangular matrix sub(*A*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of the matrix sub(*A*) contains the upper triangular part of the matrix, and the strictly lower triangular part of sub(*A*) is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of the matrix sub(*A*) contains the lower triangular part of the matrix, and the strictly upper triangular part of sub(*A*) is not referenced. If *diag* = 'U', the diagonal elements of sub(*A*) are not referenced either and are assumed to be 1.

ia, *ja*

(global) INTEGER.

The row and column indices in the global matrix *A* indicating the first row and the first column of the sub(*A*), respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

Output Parameters

a

On exit, the (triangular) inverse of the original matrix, in the same storage format.

info

INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value,

then *info* = - (*i**100+*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

?lahqr2

Updates the eigenvalues and Schur decomposition.

Syntax

```
call clahqr2 (wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, info )
call zlahqr2 (wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, info )
```

Description

?lahqr2 is an auxiliary routine called by ?hseqr to update the eigenvalues and Schur decomposition already computed by ?hseqr, by dealing with the Hessenberg submatrix in rows and columns *ilo* to *ihi*. This version of ?lahqr (not the standard LAPACK version) uses a double-shift algorithm (like LAPACK's ?lahqr). Unlike the standard LAPACK convention, this does not assume the subdiagonal is real, nor does it work to preserve this quality if given.

Input Parameters

wantt

LOGICAL.

= .TRUE.: the full Schur form *T* is required;

= .FALSE.: only eigenvalues are required.

wantz

LOGICAL.

= .TRUE.: the matrix of Schur vectors *Z* is required;

= .FALSE.: Schur vectors are not required.

n

INTEGER.

The order of the matrix *H*. *n* >= 0.

ilo, *ihi*

INTEGER.

It is assumed that the matrix *H* is upper triangular in rows and columns *ihi* +1 :*n*, and that matrix element *H*(*ilo*,*ilo*-1) = 0 (unless *ilo* = 1). ?lahqr works primarily with the Hessenberg submatrix in rows and columns *ilo* to *ihi*, but applies transformations to all of *h* if *wantt* is .TRUE..

1 <= *ilo* <= max(1,*ihi*); *ihi* <= *n*.

h

COMPLEX for clahqr2

DOUBLE COMPLEX for zlahqr2

Array, size (*ldh*,*n*).

On entry, the upper Hessenberg matrix *H*.

ldh

INTEGER.

The leading dimension of the array *h*. *ldh* >= max(1,*n*).

iloz, *ihiz*

INTEGER.

Specify the rows of *Z* to which transformations must be applied if *wantz* is .TRUE..

1 <= *iloz* <= *ilo*; *ihi* <= *ihiz* <= *n*.

z

COMPLEX for clahqr2

DOUBLE COMPLEX for zlahqr2

Array, size (*ldz*,*n*)).

If *wantz* is .TRUE., on entry *z* must contain the current matrix *Z* of transformations. If *wantz* is .FALSE., *z* is not referenced.

ldz

INTEGER.

The leading dimension of the array *z*. *ldz* >= max(1,*n*).

Output Parameters

h — On exit, if *wantt* is .TRUE., *h* is upper triangular in rows and columns *ilo*:*ihi*. If *wantt* is .FALSE., the contents of *h* are unspecified on exit.

w — COMPLEX for clahqr2

DOUBLE COMPLEX for zlahqr2

Array, size (*n*)

The computed eigenvalues *ilo* to *ihi* are stored in the corresponding elements of *w*. If *wantt* is .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*, with *w*(*i*) = *h*(*i*,*i*).

z — If *wantz* is .TRUE., on exit *z* has been updated; transformations are applied only to the submatrix *Z*(*iloz*:*ihiz*,*ilo*:*ihi*). If *wantz* is .FALSE., *z* is not referenced.

info — INTEGER.

= 0: successful exit

> 0: if *info* = *i*, ?lahqr failed to compute all the eigenvalues *ilo* to *ihi* in a total of 30*(*ihi*-*ilo*+1) iterations; elements *i*+1:*ihi* of *w* contain those eigenvalues which have been successfully computed.

?lamsh

Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.

Syntax

```
call slamsh(s, lds, nbulge, jblk, h, ldh, n, ulp)
call dlamsh(s, lds, nbulge, jblk, h, ldh, n, ulp)
call clamsh(s, lds, nbulge, jblk, h, ldh, n, ulp)
call zlamsh(s, lds, nbulge, jblk, h, ldh, n, ulp)
```

Description

The ?lamshroutine sends multiple shifts through a small (single node) matrix to see how small consecutive subdiagonal elements are modified by subsequent shifts in an effort to maximize the number of bulges that can be sent through. The subroutine should only be called when there are multiple shifts/bulges (*nbulge* > 1) and the first shift is starting in the middle of an unreduced Hessenberg matrix because of two or more small consecutive subdiagonal elements.

Input Parameters

s — (local)

REAL for slamsh

DOUBLE PRECISION for dlamsh

COMPLEX for clamsh

DOUBLE COMPLEX for zlamsh

Array of size (*lds*, 2**jblk*).

On entry, the matrix of shifts. Only the 2x2 diagonal of *s* is referenced. It is assumed that *s* has *jblk* double shifts (size 2).

lds (local) INTEGER.

On entry, the leading dimension of *S*; unchanged on exit. $1<nbulge \leq jblk \leq lds/2$.

nbulge (local) INTEGER.

On entry, the number of bulges to send through *h* (>1). *nbulge* should be less than the maximum determined (*jblk*). $1<nbulge \leq jblk \leq lds/2$.

jblk (local) INTEGER.

On entry, the number of double shifts determined for *S*; unchanged on exit.

h (local)

REAL for slamsh

DOUBLE PRECISION for dlamsh

COMPLEX for clamsh

DOUBLE COMPLEX for zlamsh

Array of size (*ldh*, *n*).

On entry, the local matrix to apply the shifts on.

h should be aligned so that the starting row is 2.

ldh (local)

INTEGER.

On entry, the leading dimension of *H*; unchanged on exit.

n (local) INTEGER.

On entry, the size of *H*. If all the bulges are expected to go through, *n* should be at least $4nbulge+2$. Otherwise, *nbulge* may be reduced by this routine.

ulp (local)

REAL for slamsh

DOUBLE PRECISION for dlamsh

REAL for clamsh

DOUBLE PRECISION for zlamsh

On entry, machine precision. Unchanged on exit.

Output Parameters

s On exit, the data is rearranged in the best order for applying.

nbulge On exit, the maximum number of bulges that can be sent through.

h	On exit, the data is destroyed.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

?lapst

Sorts the numbers in increasing or decreasing order.

Syntax

```
call slapst (id, n, d, indx, info )
call dlapst (id, n, d, indx, info )
```

Description

?lapst is a modified version of the LAPACK routine ?lasrt.

Define a permutation *indx* that sorts the numbers in *d* in increasing order (if *id* = 'I') or in decreasing order (if *id* = 'D').

Use Quick Sort, reverting to Insertion sort on arrays of size <= 20. Dimension of STACK limits *n* to about 2^{32}.

Input Parameters

id	CHARACTER*1. = 'I': sort *d* in increasing order; = 'D': sort *d* in decreasing order.
n	INTEGER. The length of the array *d*.
d	REAL for slapst DOUBLE PRECISION for dlapst Array, size (*n*) The array to be sorted.

Output Parameters

indx	INTEGER. Array, size (*n*). The permutation which sorts the array *d*.
info	INTEGER. = 0: successful exit < 0: if *info* = -i, the i-th argument had an illegal value

?laqr6

Performs a single small-bulge multi-shift QR sweep collecting the transformations.

Syntax

call slaqr6(*job*, *wantt*, *wantz*, *kacc22*, *n*, *ktop*, *kbot*, *nshfts*, *sr*, *si*, *h*, *ldh*, *iloz*, *ihiz*, *z*, *ldz*, *v*, *ldv*, *u*, *ldu*, *nv*, *wv*, *ldwv*, *nh*, *wh*, *ldwh*)

call dlaqr6(*job*, *wantt*, *wantz*, *kacc22*, *n*, *ktop*, *kbot*, *nshfts*, *sr*, *si*, *h*, *ldh*, *iloz*, *ihiz*, *z*, *ldz*, *v*, *ldv*, *u*, *ldu*, *nv*, *wv*, *ldwv*, *nh*, *wh*, *ldwh*)

Description

This auxiliary subroutine called by p?laqr5 performs a single small-bulge multi-shift QR sweep, moving the chain of bulges from top to bottom in the submatrix *H*(*ktop*:*kbot*,*ktop*:*kbot*), collecting the transformations in the matrix *V or* accumulating the transformations in the matrix *Z* (see below).

This is a modified version of ?laqr5 from LAPACK 3.1.

Input Parameters

job

CHARACTER scalar

Set the kind of job to do in ?laqr6, as follows:

job = 'I': Introduce and chase bulges in submatrix

job = 'C': Chase bulges from top to bottom of submatrix

job = 'O': Chase bulges off submatrix

wantt

LOGICAL scalar

wantt= .TRUE. if the quasi-triangular Schur factor is being computed. *wantt* is set to .FALSE. otherwise.

wantz

LOGICAL scalar

wantz= .TRUE. if the orthogonal Schur factor is being computed. *wantz* is set to .FALSE. otherwise.

kacc22

INTEGER with value 0, 1, or 2.

Specifies the computation mode of far-from-diagonal orthogonal updates.

= 0: ?laqr6 does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries.

= 1: ?laqr6 accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries.

= 2: ?laqr6 accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.

n

INTEGER scalar

n is the order of the Hessenberg matrix *H* upon which this subroutine operates.

ktop, *kbot*

INTEGER scalar

These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either *ktop* = 1 or *H*(*ktop*,*ktop*-1) = 0 and either *kbot* = *n* or *H*(*kbot* +1,*kbot*) = 0.

nshfts INTEGER scalar

nshfts gives the number of simultaneous shifts. *nshfts* must be positive and even.

sr, *si* REAL for slaqr6

DOUBLE PRECISION for dlaqr6

Array of size *nshfts*

sr contains the real parts and *si* contains the imaginary parts of the *nshfts* shifts of origin that define the multi-shift QR sweep.

h REAL for slaqr6

DOUBLE PRECISION for dlaqr6

Array of size (*ldh*,*n*)

On input *h* contains a Hessenberg matrix .

ldh INTEGER scalar

ldh is the leading dimension of *H* just as declared in the calling procedure. *ldh*≥ max(1,*n*).

iloz, *ihiz* INTEGER scalar

Specify the rows of *z* to which transformations must be applied if *wantz*is .TRUE.. 1≤*iloz*≤*ihiz*≤*n*

z REAL for slaqr6

DOUBLE PRECISION for dlaqr6

Array of size (*ldz*,*ktop*)

If *wantz*= .TRUE., then the QR sweep orthogonal similarity transformation is accumulated into the matrix *Z*(*iloz*:*ihiz*,*kbot*:*ktop*), stored in the array *z*, from the right.

If *wantz*= .FALSE., then *z* is unreferenced.

ldz INTEGER scalar

ldz is the leading dimension of *z* just as declared in the calling procedure. *ldz*≥*n*.

v REAL for slaqr6

DOUBLE PRECISION for dlaqr6

(workspace) array of size (*ldv*,*nshfts*/2)

ldv INTEGER scalar

ldv is the leading dimension of *v* as declared in the calling procedure. *ldv*≥3.

u REAL for slaqr6

DOUBLE PRECISION for dlaqr6

(workspace) array of size (*ldu*,3*nshfts*-3)

ldu INTEGER scalar

ldu is the leading dimension of *u* just as declared in the calling subroutine. *ldu*≥3**nshfts*-3.

nh INTEGER scalar

nh is the number of columns in array *wh* available for workspace. *nh*≥1 is required for usage of this workspace, otherwise the updates of the far-from-diagonal elements will be updated without level 3 BLAS.

wh REAL for slaqr6

DOUBLE PRECISION for dlaqr6

(workspace) array of size (*ldwh*,*nh*)

ldwh INTEGER scalar

Leading dimension of *wh* just as declared in the calling procedure. *ldwh*≥3**nshfts*-3.

nv INTEGER scalar

nv is the number of rows in *wv* available for workspace. *nv*≥1 is required for usage of this workspace, otherwise the updates of the far-from-diagonal elements will be updated without level 3 BLAS.

wv REAL for slaqr6

DOUBLE PRECISION for dlaqr6

(workspace) array of size (*ldwv*,3**nshfts*-3)

ldwv INTEGER scalar

ldwv is the leading dimension of *wv* as declared in the in the calling subroutine. *ldwv*≥*nv*.

OUTPUT Parameters

h A multi-shift QR sweep with shifts *sr*(*j*)+*i***si*(*j*) is applied to the isolated diagonal block in rows and columns *ktop* through *kbot*.

z If *wantz* is .TRUE., then the QR sweep orthogonal/unitary similarity transformation is accumulated into the matrix *Z*(*iloz*:*ihiz*,*kbot*:*ktop*) from the right.

If *wantz* is .FALSE., then *z* is unreferenced.

Application Notes

Notes

Based on contributions by Karen Braman and Ralph Byers, Department of Mathematics, University of Kansas, USA Robert Granat, Department of Computing Science and HPC2N, Umea University, Sweden

Overview for details of ScaLAPACK array descriptor structures and related notations.

?lar1va

Computes scaled eigenvector corresponding to given eigenvalue.

Syntax

`call slar1va(n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc, negcnt, ztz, mingma, r, isuppz, nrminv, resid, rqcorr, work )`

`call dlar1va(n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc, negcnt, ztz, mingma, r, isuppz, nrminv, resid, rqcorr, work )`

Description

`?slar1va` computes the (scaled) r-th column of the inverse of the submatrix in rows `b1` through `bn` of the tridiagonal matrix $LDL^T - \lambda I$. When λ is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually, `r` corresponds to the index where the eigenvector is largest in magnitude. The following steps accomplish this computation :

1. Stationary qd transform, $LDL^T - \lambda I = L_+D_+L_+^T$,
2. Progressive qd transform, $LDL^T - \lambda I = U_-D_-U_-^T$,
3. Computation of the diagonal elements of the inverse of $LDL^T - \lambda I$ by combining the above transforms, and choosing `r` as the index where the diagonal of the inverse is (one of the) largest in magnitude.
4. Computation of the (scaled) `r`-th column of the inverse using the twisted factorization obtained by combining the top part of the stationary and the bottom part of the progressive transform.

Input Parameters

`n`

`INTEGER`

The order of the matrix LDL^T.

`b1`

`INTEGER`

First index of the submatrix of LDL^T.

`bn`

`INTEGER`

Last index of the submatrix of LDL^T.

`lambda`

`REAL` for `slar1va`

`DOUBLE PRECISION` for `dlar1va`

The shift λ. In order to compute an accurate eigenvector, `lambda` should be a good approximation to an eigenvalue of LDL^T.

`l`

`REAL` for `slar1va`

`DOUBLE PRECISION` for `dlar1va`

Array of size `n`-1

The (`n`-1) subdiagonal elements of the unit bidiagonal matrix L, in elements 1 to `n`-1.

`d`

`REAL` for `slar1va`

`DOUBLE PRECISION` for `dlar1va`

Array of size `n`

The n diagonal elements of the diagonal matrix D.

ld

REAL for slar1va

DOUBLE PRECISION for dlar1va

Array of size n-1

The n-1 elements $l(i)*d(i)$.

lld

REAL for slar1va

DOUBLE PRECISION for dlar1va

Array of size n-1

The n-1 elements $l(i)*l(i)*d(i)$.

pivmin

REAL for slar1va

DOUBLE PRECISION for dlar1va

The minimum pivot in the Sturm sequence.

gaptol

REAL for slar1va

DOUBLE PRECISION for dlar1va

Tolerance that indicates when eigenvector entries are negligible with respect to their contribution to the residual.

z

REAL for slar1va

DOUBLE PRECISION for dlar1va

Array of size n

On input, all entries of z must be set to 0.

wantnc

LOGICAL

Specifies whether *negcnt* has to be computed.

r

INTEGER

The twist index for the twisted factorization used to compute z.

On input, $0 \le r \le n$. If r is input as 0, r is set to the index where $(LDL^T - \sigma I)^{-1}$ is largest in magnitude. If $1 \le r \le n$, r is unchanged.

Ideally, r designates the position of the maximum entry in the eigenvector.

work

REAL for slar1va

DOUBLE PRECISION for dlar1va

(Workspace) array of size 4*n

OUTPUT Parameters

z

On output, z contains the (scaled) r-th column of the inverse. The scaling is such that $z(r)$ equals 1.

negcnt

INTEGER

If *wantnc*is .TRUE. then *negcnt* = the number of pivots < *pivmin* in the matrix factorization LDL^T, and *negcnt* = -1 otherwise.

ztz

REAL for slar1va

DOUBLE PRECISION for dlar1va

The square of the 2-norm of *z*.

mingma

REAL for slar1va

DOUBLE PRECISION for dlar1va

The reciprocal of the largest (in magnitude) diagonal element of the inverse of $LDL^T - \sigma I$.

r

On output, *r* contains the twist index used to compute *z*.

isuppz

INTEGER array of size 2

The support of the vector in *z*, i.e., the vector *z* is non-zero only in elements *isuppz*(1) through *isuppz*(2).

nrminv

REAL for slar1va

DOUBLE PRECISION for dlar1va

nrminv = 1/SQRT(*ztz*)

resid

REAL for slar1va

DOUBLE PRECISION for dlar1va

The residual of the FP vector.

resid = ABS(*mingma*)/SQRT(*ztz*)

rqcorr

REAL for slar1va

DOUBLE PRECISION for dlar1va

The Rayleigh Quotient correction to *lambda*.

?laref

Applies Householder reflectors to matrices on their rows or columns.

Syntax

```
call slaref (type, a, lda, wantz, z, ldz, block, irow1, icol1, istart, istop, itmp1,
itmp2, liloz, lihiz, vecs, v2, v3, t1, t2, t3 )
```

```
call dlaref (type, a, lda, wantz, z, ldz, block, irow1, icol1, istart, istop, itmp1,
itmp2, liloz, lihiz, vecs, v2, v3, t1, t2, t3 )
```

```
call claref (type, a, lda, wantz, z, ldz, block, irow1, icol1, istart, istop, itmp1,
itmp2, liloz, lihiz, vecs, v2, v3, t1, t2, t3 )
```

```
call zlaref (type, a, lda, wantz, z, ldz, block, irow1, icol1, istart, istop, itmp1,
itmp2, liloz, lihiz, vecs, v2, v3, t1, t2, t3 )
```

Description

?laref applies one or several Householder reflectors of size 3 to one or two matrices (if column is specified) on either their rows or columns.

Input Parameters

type

(local)

CHARACTER*1.

If 'R': Apply reflectors to the rows of the matrix (apply from left)

Otherwise: Apply reflectors to the columns of the matrix

Unchanged on exit.

a

(local)

REAL for slaref

DOUBLE PRECISION for dlaref

COMPLEX for claref

DOUBLE COMPLEX for zlaref

Array, (*lld_a*,*LOCc*(*ja*+*n*-1))

On entry, the matrix to receive the reflections.

lda

(local)

INTEGER.

On entry, the leading dimension of *a*.

Unchanged on exit.

wantz

(local)

LOGICAL.

If .TRUE., then apply any column reflections to *z* as well.

If .FALSE., then do no additional work on *z*.

z

(local)

REAL for slaref

DOUBLE PRECISION for dlaref

COMPLEX for claref

DOUBLE COMPLEX for zlaref

Array, (*ldz*,*ncols*), where the value *ncols* depends on other arguments. If *wantz*== .TRUE. and *type*≠ 'R' then *ncols* = *icol1* + 3*(*lihiz* - *liloz* + 1). Otherwise, *ncols* is unused.

On entry, the second matrix to receive column reflections.

This is changed only if *wantz* is set.

ldz

(local)

INTEGER.

On entry, the leading dimension of *z*.

Unchanged on exit.

block (local)

LOGICAL.

If .TRUE., then apply several reflectors at once and read their data from the *vecs* array.

If .FALSE., apply the single reflector given by *v2*, *v3*, *t1*, *t2*, and *t3*.

irow1 (local)

INTEGER.

On entry, the local row element of *a*.

icol1 (local)

INTEGER.

On entry, the local column element of *a*.

istart (local)

INTEGER.

Specifies the "number" of the first reflector. This is used as an index into *vecs* if *block* is set. *istart* is ignored if *block* is .FALSE..

istop (local)

INTEGER.

Specifies the "number" of the last reflector. This is used as an index into *vecs* if *block* is set. *istop* is ignored if *block* is .FALSE..

itmp1 (local)

INTEGER.

Starting range into *a*. For rows, this is the local first column. For columns, this is the local first row.

itmp2 (local)

INTEGER.

Ending range into *a*. For rows, this is the local last column. For columns, this is the local last row.

liloz, *lihiz* (local)

INTEGER.

These serve the same purpose as *itmp1*, *itmp2* but for *z* when *wantz* is set.

vecs (local)

`REAL` for `slaref`

`DOUBLE PRECISION` for `dlaref`

`COMPLEX` for `claref`

	`DOUBLE COMPLEX` for `zlaref` Array of size 3*N (matrix size) This holds the size 3 reflectors one after another and this is only accessed when *block* is .TRUE.

v2, *v3*, *t1*, *t2*, *t3*	(local)
	`REAL` for `slaref`
	`DOUBLE PRECISION` for `dlaref`
	`COMPLEX` for `claref`
	`DOUBLE COMPLEX` for `zlaref`
	This holds information on a single size 3 Householder reflector and is read when *block* is .FALSE., and overwritten when *block* is .TRUE.

Output Parameters

a	The updated matrix on exit.
z	This is changed only if *wantz* is set.
irow1	Undefined on output.
icol1	Undefined on output.
v2, *v3*, *t1*, *t2*, *t3*	Overwritten when *block* is .TRUE.

?larrb2

Provides limited bisection to locate eigenvalues for more accuracy.

Syntax

```
call slarrb2( n, d, lld, ifirst, ilast, rtol1, rtol2, offset, w, wgap, werr, work,
iwork, pivmin, lgpvmn, lgspdm, twist, info )
```

```
call dlarrb2( n, d, lld, ifirst, ilast, rtol1, rtol2, offset, w, wgap, werr, work,
iwork, pivmin, lgpvmn, lgspdm, twist, info )
```

Description

Given the relatively robust representation (RRR) LDL^T, `?larrb2` does "limited" bisection to refine the eigenvalues of LDL^T, *w*(*ifirst* - *offset*) through *w*(*ilast* - *offset*), to more accuracy. Initial guesses for these eigenvalues are input in *w*, the corresponding estimate of the error in these guesses and their gaps are input in *werr* and *wgap*, respectively. During bisection, intervals [*left*, *right*] are maintained by storing their mid-points and semi-widths in the arrays *w* and *werr* respectively.

NOTE
There are very few minor differences between larrb from LAPACK and this current subroutine ?larrb2. The most important reason for creating this nearly identical copy is profiling: in the ScaLAPACK MRRR algorithm, eigenvalue computation using ?larrb2 is used for refinement in the construction of the representation tree, as opposed to the initial computation of the eigenvalues for the root RRR which uses ?larrb. When profiling, this allows an easy quantification of refinement work vs. computing eigenvalues of the root.

Input Parameters

n INTEGER

The order of the matrix.

d REAL for slarrb2

DOUBLE PRECISION for dlarrb2

Array of size *n*.

The *n* diagonal elements of the diagonal matrix *D*.

lld REAL for slarrb2

DOUBLE PRECISION for dlarrb2

Array of size *n*-1.

The (*n*-1) elements $l_i * l_i * d(i)$.

ifirst INTEGER

The index of the first eigenvalue to be computed.

ilast INTEGER

The index of the last eigenvalue to be computed.

rtol1, *rtol2* REAL for slarrb2

DOUBLE PRECISION for dlarrb2

Tolerance for the convergence of the bisection intervals.

An interval [*left*, *right*] has converged if *right* - *left* < max (*rtol1* * *gap*, *rtol2* * max(|*left*|, |*right*|)) where *gap* is the (estimated) distance to the nearest eigenvalue.

offset INTEGER

Offset for the arrays *w*, *wgap* and *werr*, i.e., the *ifirst* - *offset* through *ilast* - *offset* elements of these arrays are to be used.

w REAL for slarrb2

DOUBLE PRECISION for dlarrb2

Array of size *n*

On input, *w*(*ifirst* - *offset*) through *w*(*ilast*- *offset*) are estimates of the eigenvalues of LDL^T indexed *ifirst* through *ilast*.

wgap REAL for slarrb2

DOUBLE PRECISION for dlarrb2

Array of size *n*-1.

On input, the (estimated) gaps between consecutive eigenvalues of LDL^T, i.e., *wgap*(*I* - *offset*) is the gap between eigenvalues *I* and *I* + 1. Note that if *ifirst* = *ilast* then *wgap*(*ifirst* - *offset*) must be set to zero.

werr

REAL for slarrb2

DOUBLE PRECISION for dlarrb2

Array of size *n*.

On input, *werr*(*ifirst* - *offset*) through *werr*(*ilast* - *offset*) are the errors in the estimates of the corresponding elements in *w*.

work

REAL for slarrb2

DOUBLE PRECISION for dlarrb2

(workspace) array of size 4**n*.

Workspace.

iwork

(workspace) INTEGER array of size 2**n*.

Workspace.

pivmin

REAL for slarrb2

DOUBLE PRECISION for dlarrb2

The minimum pivot in the Sturm sequence.

lgpvmn

REAL for slarrb2

DOUBLE PRECISION for dlarrb2

Logarithm of *pivmin*, precomputed.

lgspdm

REAL for slarrb2

DOUBLE PRECISION for dlarrb2

Logarithm of the spectral diameter, precomputed.

twist

INTEGER

The twist index for the twisted factorization that is used for the *negcount*.

twist = *n*: Compute *negcount* from $LDL^T - \lambda I = L_+ D_+ L_+^T$

twist = 1: Compute *negcount* from $LDL^T - \lambda I = U_- D_- U_-^T$

twist = *r*, 1 < *r* < *n*: Compute *negcount* from $LDL^T - \lambda I = N_r \Delta_r N_r^T$

OUTPUT Parameters

w

On output, the eigenvalue estimates in *w* are refined.

wgap

On output, the eigenvalue gaps in *wgap* are refined.

werr

On output, the errors in *werr* are refined.

info

INTEGER

Error flag.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

?larrd2

Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.

Syntax

```
call slarrd2( range, order, n, vl, vu, il, iu, gers, reltol, d, e, e2, pivmin, nsplit, isplit, m, w, werr, wl, wu, iblock, indexw, work, iwork, dol, dou, info )
```

```
call dlarrd2( range, order, n, vl, vu, il, iu, gers, reltol, d, e, e2, pivmin, nsplit, isplit, m, w, werr, wl, wu, iblock, indexw, work, iwork, dol, dou, info )
```

Description

`?larrd2` computes the eigenvalues of a symmetric tridiagonal matrix *T* to limited initial accuracy. This is an auxiliary code to be called from larre2a.

`?larrd2` has been created using the LAPACK code larrd which itself stems from stebz. The motivation for creating `?larrd2` is efficiency: When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, `?larrd2` can skip over blocks which contain none of the eigenvalues from DOL to DOU for which the processor responsible. In extreme cases (such as large matrices consisting of many blocks of small size like 2x2), the gain can be substantial.

Input Parameters

range

`CHARACTER`

= 'A': ("All") all eigenvalues will be found.

= 'V': ("Value") all eigenvalues in the half-open interval (*vl*, *vu*] will be found.

= 'I': ("Index") the *il*-th through *iu*-th eigenvalues (of the entire matrix) will be found.

order

`CHARACTER`

= 'B': ("By Block") the eigenvalues will be grouped by split-off block (see *iblock*, *isplit*) and ordered from smallest to largest within the block.

= 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.

n

`INTEGER`

The order of the tridiagonal matrix *T*. *n* >= 0.

vl, *vu*

`REAL` for `slarrd2`

DOUBLE PRECISION for dlarrd2

If *range*='V', the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to *vl*, or greater than *vu*, will not be returned. *vl* < *vu*.

Not referenced if *range* = 'A' or 'I'.

il, *iu*

INTEGER

If *range*='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned.

1 ≤*il*≤*iu*≤=*n*, if *n* > 0; *il* = 1 and *iu* = 0 if *n* = 0.

Not referenced if *range* = 'A' or 'V'.

gers

REAL for slarrd2

DOUBLE PRECISION for dlarrd2

Array of size 2**n*

The *n* Gerschgorin intervals (the *i*-th Gerschgorin interval is (*gers*(2**i*-1), *gers*(2**i*))).

reltol

REAL for slarrd2

DOUBLE PRECISION for dlarrd2

The minimum relative width of an interval. When an interval is narrower than *reltol* times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least radix*machine epsilon.

d

REAL for slarrd2

DOUBLE PRECISION for dlarrd2

Array of size *n*

The *n* diagonal elements of the tridiagonal matrix *T*.

e

REAL for slarrd2

DOUBLE PRECISION for dlarrd2

Array of size *n*-1

The (*n*-1) off-diagonal elements of the tridiagonal matrix *T*.

e2

REAL for slarrd2

DOUBLE PRECISION for dlarrd2

Array of size *n*-1

The (*n*-1) squared off-diagonal elements of the tridiagonal matrix *T*.

pivmin

REAL for slarrd2

DOUBLE PRECISION for dlarrd2

The minimum pivot allowed in the sturm sequence for *T*.

nsplit

INTEGER

The number of diagonal blocks in the matrix *T*.

1 ≤*nsplit*≤*n*.

isplit INTEGERArray of size *n*

The splitting points, at which *T* breaks up into submatrices.

The first submatrix consists of rows/columns 1 to *isplit*(1), the second of rows/columns *isplit*(1)+1 through *isplit*(2), etc., and the *nsplit*-th submatrix consists of rows/columns *isplit*(*nsplit*-1)+1 through *isplit*(*nsplit*)=*n*.

(Only the first *nsplit* elements will actually be used, but since the user cannot know a priori what value *nsplit* will have, *n* words must be reserved for *isplit*.)

work REAL for slarrd2

DOUBLE PRECISION for dlarrd2

(workspace) Array of size 4**n*

iwork (workspace) INTEGER Array of size 3**n*

dol, *dou* INTEGER

Specifying an index range *dol*:*dou* allows the user to work on only a selected part of the representation tree.

Otherwise, the setting *dol*=1, *dou*=*n* should be applied.

Note that *dol* and *dou* refer to the order in which the eigenvalues are stored in W.

OUTPUT Parameters

m INTEGER

The actual number of eigenvalues found. 0 ≤*m*≤*n*.

(See also the description of *info*=2,3.)

w REAL for slarrd2

DOUBLE PRECISION for dlarrd2

Array of size *n*

On exit, the first *m* elements of *w* will contain the eigenvalue approximations. ?larrd2 computes an interval $I_j = (a_j, b_j]$ that includes eigenvalue *j*. The eigenvalue approximation is given as the interval midpoint *w*(*j*)= $(a_j + b_j)/2$. The corresponding error is bounded by *werr*(*j*) = abs(a_j - b_j)/2.

werr REAL for slarrd2

DOUBLE PRECISION for dlarrd2

Array of size *n*

The error bound on the corresponding eigenvalue approximation in *w*.

wl, *wu* REAL for slarrd2

DOUBLE PRECISION for dlarrd2

The interval (*wl*, *wu*] contains all the wanted eigenvalues.

If *range*='V', then *wl*=*vl* and *wu*=*vu*.

If *range*='A', then *wl* and *wu* are the global Gerschgorin bounds

on the spectrum.

If *range*='I', then *wl* and *wu* are computed by SLAEBZ from the

index range specified.

iblock

INTEGERArray of size *n*

At each row/column *j* where *e*(*j*) is zero or small, the matrix *T* is considered to split into a block diagonal matrix. On exit, if *info* = 0, *iblock*(*i*) specifies to which block (from 1 to the number of blocks) the eigenvalue *w*(*i*) belongs. (?larrd2 may use the remaining *n*-*m* elements as workspace.)

indexw

INTEGERArray of size *n*

The indices of the eigenvalues within each block (submatrix); for example, *indexw*(*i*)= *j* and *iblock*(*i*)=*k* imply that the *i*-th eigenvalue *w*(*i*) is the *j*-th eigenvalue in block *k*.

info

INTEGER

= 0: successful exit

< 0: if *info* = -*i*, the *i*-th argument had an illegal value

> 0: some or all of the eigenvalues failed to converge or were not computed:

- =1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.
- =2 or 3: *range*='I' only: Not all of the eigenvalues *il*:*iu* were found.
- = 4: *range*='I', and the Gershgorin interval initially used was too small. No eigenvalues were computed.

?larre2

Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.

Syntax

call slarre2(*range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit, isplit, m, dol, dou, w, werr, wgap, iblock, indexw, gers, pivmin, work, iwork, info*)

call dlarre2(*range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit, isplit, m, dol, dou, w, werr, wgap, iblock, indexw, gers, pivmin, work, iwork, info*)

Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix *T*, `?larre2` sets, via `?larra`, "small" off-diagonal elements to zero. For each block T_i, it finds

- a suitable shift at one end of the block's spectrum,
- the root RRR, $T_i - \sigma_i I = L_i D_i L_i^T$, and
- eigenvalues of each $L_i D_i L_i^T$.

The representations and eigenvalues found are then returned to `?stegr2` to compute the eigenvectors *T*.

`?larre2` is more suitable for parallel computation than the original LAPACK code for computing the root RRR and its eigenvalues. When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, `?larre2` can skip over blocks which contain none of the eigenvalues from *dol* to *dou* for which the processor is responsible. In extreme cases (such as large matrices consisting of many blocks of small size, e.g. 2x2), the gain can be substantial.

Input Parameters

range

`CHARACTER`

= 'A': ("All") all eigenvalues will be found.

= 'V': ("Value") all eigenvalues in the half-open interval (*vl*, *vu*] will be found.

= 'I': ("Index") the *il*-th through *iu*-th eigenvalues (of the entire matrix) will be found.

n

`INTEGER`

The order of the matrix. $n > 0$.

vl, *vu*

`REAL` for `slarre2`

`DOUBLE PRECISION` for `dlarre2`

If *range*='V', the lower and upper bounds for the eigenvalues.

Eigenvalues less than or equal to *vl*, or greater than *vu*, will not be returned. $vl < vu$.

il, *iu*

`INTEGER`

If *range*='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned.

$1 \le il \le iu \le n$.

d

`REAL` for `slarre2`

`DOUBLE PRECISION` for `dlarre2`

Array of size *n*

The *n* diagonal elements of the tridiagonal matrix *T*.

e

REAL for slarre2

DOUBLE PRECISION for dlarre2

Array of size *n*

The first (*n*-1) entries contain the subdiagonal elements of the tridiagonal matrix *T*; *e*(*n*) need not be set.

e2

REAL for slarre2

DOUBLE PRECISION for dlarre2

Array of size *n*

The first (*n*-1) entries contain the squares of the subdiagonal elements of the tridiagonal matrix *T*; *e2*(*n*) need not be set.

rtol1, *rtol2*

REAL for slarre2

DOUBLE PRECISION for dlarre2

Parameters for bisection.

An interval [*left*, *right*] has converged if *right-left*<max(*rtol1***gap*, *rtol2**max(|*left*|,|*right*|))

spltol

REAL for slarre2

DOUBLE PRECISION for dlarre2

The threshold for splitting.

dol, *dou*

INTEGER

Specifying an index range *dol*:*dou* allows the user to work on only a selected part of the representation tree. Otherwise, the setting *dol*=1, *dou*=*n* should be applied.

Note that *dol* and *dou* refer to the order in which the eigenvalues are stored in *w*.

work

REAL for slarre2

DOUBLE PRECISION for dlarre2

Workspace array of size 6**n*

iwork

INTEGER

Workspace array of size 5**n*

OUTPUT Parameters

vl, *vu*

If *range*='I' or ='A', ?larre2 contains bounds on the desired part of the spectrum.

d

The *n* diagonal elements of the diagonal matrices D_i.

e

e contains the subdiagonal elements of the unit bidiagonal matrices L_i. The entries *e*(*isplit*(*i*)), 1 ≤*j*≤*nsplit*, contain the base points σ_i on output.

e2

The entries *e2*(*isplit*(*i*)), 1 ≤*j*≤*nsplit*, are set to zero.

nsplit INTEGER

The number of blocks *T* splits into. 1 ≤*nsplit*≤*n*.

isplit INTEGERArray of size *n*

The splitting points, at which *T* breaks up into blocks.

The first block consists of rows/columns 1 to *isplit*(1), the second of rows/columns *isplit*(1)+1 through *isplit*(2), etc., and the *nsplit*-th block consists of rows/columns *isplit*(*nsplit*-1)+1 through *isplit*(*nsplit*)=*n*.

m INTEGER

The total number of eigenvalues (of all $L_iD_iL_i^T$) found.

w REAL for slarre2

DOUBLE PRECISION for dlarre2

Array of size *n*

The first *m* elements contain the eigenvalues. The eigenvalues of each of the blocks, $L_iD_iL_i^T$, are sorted in ascending order (?larre2 may use the remaining *n*-*m* elements as workspace).

Note that immediately after exiting this routine, only the eigenvalues from position *dol*:*dou* in *w* might rely on this processor when the eigenvalue computation is done in parallel.

werr REAL for slarre2

DOUBLE PRECISION for dlarre2

Array of size *n*

The error bound on the corresponding eigenvalue in *w*.

Note that immediately after exiting this routine, only the uncertainties from position *dol*:*dou* in *werr* might rely on this processor when the eigenvalue computation is done in parallel.

wgap REAL for slarre2

DOUBLE PRECISION for dlarre2

Array of size *n*

The separation from the right neighbor eigenvalue in *w*.

The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree.

Exception: at the right end of a block we store the left gap

Note that immediately after exiting this routine, only the gaps from position *dol*:*dou* in *wgap* might rely on this processor when the eigenvalue computation is done in parallel.

iblock INTEGERArray of size *n*

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in *w*; *iblock*(*i*)=1 if eigenvalue *w*(*i*) belongs to the first block from the top, *iblock*(*i*)=2 if *w*(*i*) belongs to the second block, and so on.

indexw

INTEGERArray of size *n*

The indices of the eigenvalues within each block (submatrix); for example, *indexw*(*i*)= 10 and *iblock*(*i*)=2 imply that the *i*-th eigenvalue *w*(*i*) is the 10th eigenvalue in block 2.

gers

REAL for slarre2

DOUBLE PRECISION for dlarre2

Array of size 2**n*

The *n* Gerschgorin intervals (the *i*-th Gerschgorin interval is (*gers*(2**i*-1), *gers*(2**i*))).

pivmin

REAL for slarre2

DOUBLE PRECISION for dlarre2

The minimum pivot in the sturm sequence for *T*.

info

INTEGER

= 0: successful exit

> 0: A problem occurred in ?larre2.

< 0: One of the called subroutines signaled an internal problem.

Needs inspection of the corresponding parameter *info* for further information.

=-1: Problem in ?larrd.

=-2: Not enough internal iterations to find the base representation.

=-3: Problem in ?larrb when computing the refined root representation for ?lasq2.

=-4: Problem in ?larrb when preforming bisection on the desired part of the spectrum.

=-5: Problem in ?lasq2

=-6: Problem in ?lasq2

?larre2a

Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.

Syntax

```
call slarre2a( range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit, isplit,
m, dol, dou, needil, neediu, w, werr, wgap, iblock, indexw, gers, sdiam, pivmin, work,
iwork, minrgp, info )
```

```
call dlarre2a( range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit, isplit,
m, dol, dou, needil, neediu, w, werr, wgap, iblock, indexw, gers, sdiam, pivmin, work,
iwork, minrgp, info )
```

Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix T, `?larre2a` sets any "small" off-diagonal elements to zero, and for each unreduced block T_i, it finds

- a suitable shift at one end of the block's spectrum,
- the base representation, $T_i - \sigma_i I = L_i D_i L_i^T$, and
- eigenvalues of each $L_i D_i L_i^T$.

> **NOTE**
> The algorithm obtains a crude picture of all the wanted eigenvalues (as selected by *range*). However, to reduce work and improve scalability, only the eigenvalues *dol* to *dou* are refined. Furthermore, if the matrix splits into blocks, RRRs for blocks that do not contain eigenvalues from *dol* to *dou* are skipped. The DQDS algorithm (subroutine `?lasq2`) is not used, unlike in the sequential case. Instead, eigenvalues are computed in parallel to some figures using bisection.

Input Parameters

range

`CHARACTER`

= 'A': ("All") all eigenvalues will be found.

= 'V': ("Value") all eigenvalues in the half-open interval (*vl*, *vu*] will be found.

= 'I': ("Index") the *il*-th through *iu*-th eigenvalues (of the entire matrix) will be found.

n

`INTEGER`

The order of the matrix. $n > 0$.

vl, *vu*

`REAL` for `slarre2a`

`DOUBLE PRECISION` for `dlarre2a`

If *range*='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to *vl*, or greater than *vu*, will not be returned. $vl < vu$.

If *range*='I' or ='A', `?larre2a` computes bounds on the desired part of the spectrum.

il, *iu*

`INTEGER`

If *range*='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned.

$1 \le il \le iu \le n$.

d

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

Array of size *n*

On entry, the *n* diagonal elements of the tridiagonal matrix *T*.

e

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

Array of size *n*

The first (*n*-1) entries contain the subdiagonal elements of the tridiagonal matrix *T*; *e*(*n*) need not be set.

e2

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

Array of size *n*

The first (*n*-1) entries contain the squares of the subdiagonal elements of the tridiagonal matrix *T*; *e2*(*n*) need not be set.

rtol1, *rtol2*

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

Parameters for bisection.

An interval [*left*,*right*] has converged if *right* - *left* < max(*rtol1***gap*, *rtol2**max(|*left*|,|*right*|))

spltol

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

The threshold for splitting.

dol, *dou*

INTEGER

If the user wants to work on only a selected part of the representation tree, he can specify an index range *dol*:*dou*.

Otherwise, the setting *dol*=1, *dou*=*n* should be applied.

Note that *dol* and *dou* refer to the order in which the eigenvalues are stored in *w*.

work

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

Workspace array of size 6**n*

iwork

INTEGER

Workspace array of size 5**n*

minrgp

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached.

OUTPUT Parameters

vl, *vu*

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

If *range*='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to *vl*, or greater than *vu*, are not returned. *vl* < *vu*.

If *range*='I' or *range*='A', ?larre2a computes bounds on the desired part of the spectrum.

d

The *n* diagonal elements of the diagonal matrices D_i.

e

e contains the subdiagonal elements of the unit bidiagonal matrices L_i. The entries *e*(*isplit*(*i*)), 1 ≤*i*≤*nsplit*, contain the base points σ_i on output.

e2

The entries *e2*(*isplit*(*i*)), 1 ≤*i*≤*nsplit* have been set to zero.

nsplit

INTEGER

The number of blocks *T* splits into. 1 ≤*nsplit*≤*n*.

isplit

INTEGER

Array of size *n*

The splitting points, at which *T* breaks up into blocks.

The first block consists of rows/columns 1 to *isplit*(1), the second of rows/columns *isplit*(1)+1 through *isplit*(2), etc., and the *nsplit*-th block consists of rows/columns *isplit*(*nsplit*-1)+1 through *isplit*(*nsplit*)=*n*.

m

INTEGER

The total number of eigenvalues (of all $L_iD_iL_i^T$) found.

needil, *neediu*

INTEGER

The indices of the leftmost and rightmost eigenvalues of the root node RRR which are needed to accurately compute the relevant part of the representation tree.

w

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

Array of size *n*

The first *m* elements contain the eigenvalues. The eigenvalues of each of the blocks, $L_iD_iL_i^T$, are sorted in ascending order (?larre2a may use the remaining *n*-*m* elements as workspace).

Note that immediately after exiting this routine, only the eigenvalues from position *dol*:*dou* in *w* rely on this processor because the eigenvalue computation is done in parallel.

werr

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

Array of size *n*

The error bound on the corresponding eigenvalue in *w*.

Note that immediately after exiting this routine, only the uncertainties from position *dol*:*dou* in *werr* are reliable on this processor because the eigenvalue computation is done in parallel.

wgap

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

Array of size *n*

The separation from the right neighbor eigenvalue in *w*. The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree.

Exception: at the right end of a block we store the left gap

Note that immediately after exiting this routine, only the gaps from position *dol*:*dou* in *wgap* are reliable on this processor because the eigenvalue computation is done in parallel.

iblock

INTEGERArray of size *n*

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in *w*; *iblock*(*i*)=1 if eigenvalue *w*(*i*) belongs to the first block from the top, *iblock*(*i*)=2 if *w*(*i*) belongs to the second block, and so on.

indexw

INTEGERArray of size *n*

The indices of the eigenvalues within each block (submatrix); for example, *indexw*(*i*)= 10 and *iblock*(*i*)=2 imply that the *i*-th eigenvalue *w*(*i*) is the 10th eigenvalue in block 2.

gers

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

Array of size 2*n*

The *n* Gerschgorin intervals (the *i*-th Gerschgorin interval is (*gers*(2**i*-1), *gers*(2**i*))).

pivmin

REAL for slarre2a

DOUBLE PRECISION for dlarre2a

The minimum pivot in the sturm sequence for *T*.

info

INTEGER

= 0: successful exit

> 0: A problem occurred in ?larre2a.

< 0: One of the called subroutines signaled an internal problem. Needs inspection of the corresponding parameter *info* for further information.

=-1: Problem in ?larrd2.

=-2: Not enough internal iterations to find base representation.

=-3: Problem in ?larrb2 when computing the refined root representation.

=-4: Problem in ?larrb2 when preforming bisection on the desired part of the spectrum.

= -9 Problem: *m* < *dou-dol*+1, that is the code found fewer eigenvalues than it was supposed to.

?larrf2

Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.

Syntax

```
call slarrf2( n, d, l, ld, clstrt, clend, clmid1, clmid2, w, wgap, werr, trymid, spdiam, clgapl, clgapr, pivmin, sigma, dplus, lplus, work, info )
```

```
call dlarrf2( n, d, l, ld, clstrt, clend, clmid1, clmid2, w, wgap, werr, trymid, spdiam, clgapl, clgapr, pivmin, sigma, dplus, lplus, work, info )
```

Description

Given the initial representation LDL^T and its cluster of close eigenvalues (in a relative measure), *w*(*clstrt*), *w*(*clstrt*+1), ... *w*(*clend*), ?larrf2 finds a new relatively robust representation $LDL^T - \sigma I = L_+D_+L_+^T$ such that at least one of the eigenvalues of $L_+D_+L_+^T$ is relatively isolated.

This is an enhanced version of ?larrf that also tries shifts in the middle of the cluster, should there be a large gap, in order to break large clusters into at least two pieces.

Input Parameters

n

INTEGER

The order of the matrix (subblock, if the matrix was split).

d

REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Array of size *n*

The *n* diagonal elements of the diagonal matrix *D*.

l

REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Array of size *n*-1

The (*n*-1) subdiagonal elements of the unit bidiagonal matrix *L*.

ld

REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Array of size *n*-1

The (*n*-1) elements *l*(*i*)**d*(*i*).

clstrt

INTEGER

The index of the first eigenvalue in the cluster.

clend INTEGER

The index of the last eigenvalue in the cluster.

clmid1, *clmid2* INTEGER

The index of a middle eigenvalue pair with large gap.

w REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Array of size ≥ (*clend*-*clstrt*+1)

The eigenvalue approximations of *LD* L^T in ascending order. *w*(*clstrt*) through *w*(*clend*) form the cluster of relatively close eigenalues.

wgap REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Array of size ≥ (*clend*-*clstrt*+1)

The separation from the right neighbor eigenvalue in *w*.

werr REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Array of size ≥ (*clend*-*clstrt*+1)

werr contains the semiwidth of the uncertainty interval of the corresponding eigenvalue approximation in *w*.

spdiam REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Estimate of the spectral diameter obtained from the Gerschgorin intervals

clgapl, *clgapr* REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Absolute gap on each end of the cluster.

Set by the calling routine to protect against shifts too close to eigenvalues outside the cluster.

pivmin REAL for slarrf2

DOUBLE PRECISION for dlarrf2

The minimum pivot allowed in the Sturm sequence.

work REAL for slarrf2

DOUBLE PRECISION for dlarrf2

Workspace array of size 2**n*

OUTPUT Parameters

wgap Contains refined values of its input approximations. Very small gaps are unchanged.

sigma
REAL for slarrf2
DOUBLE PRECISION for dlarrf2
The shift (σ) used to form $L_+D_+L_+^T$.

dplus
REAL for slarrf2
DOUBLE PRECISION for dlarrf2
Array of size *n*
The *n* diagonal elements of the diagonal matrix D_+.

lplus
REAL for slarrf2
DOUBLE PRECISION for dlarrf2
Array of size *n*-1
The first (*n*-1) elements of *lplus* contain the subdiagonal elements of the unit bidiagonal matrix L_+.

rtol1, rtol2, w, werr, wgap, iblock, indexw, gers, sdiam, z, ldz, isuppz, work, iwork,
vstart, finish, maxcls, ndepth, parity, zoffset, info )
```

```
call dlarrv2( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, needil, neediu, minrgp,
rtol1, rtol2, w, werr, wgap, iblock, indexw, gers, sdiam, z, ldz, isuppz, work, iwork,
vstart, finish, maxcls, ndepth, parity, zoffset, info )
```

Description

?larrv2 computes the eigenvectors of the tridiagonal matrix $T = LDL^T$ given L, D and approximations to the eigenvalues of LDL^T. The input eigenvalues should have been computed by larre2a or by previous calls to ?larrv2.

The major difference between the parallel and the sequential construction of the representation tree is that in the parallel case, not all eigenvalues of a given cluster might be computed locally. Other processors might "own" and refine part of an eigenvalue cluster. This is crucial for scalability. Thus there might be communication necessary before the current level of the representation tree can be parsed.

Please note:

- The calling sequence has two additional integer parameters, *dol* and *dou*, that should satisfy *m*≥*dou*≥*dol*≥1. These parameters are only relevant when both eigenvalues and eigenvectors are computed (stegr2b parameter *jobz* = 'V'). ?larrv2 only computes the eigenvectors corresponding to eigenvalues *dol* through *dou* in *w*. (That is, instead of computing the eigenvectors belonging to *w*(1) through *w*(*m*), only the eigenvectors belonging to eigenvalues *w*(*dol*) through *w*(*dou*) are computed. In this case, only the eigenvalues *dol*:*dou* are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.

- The additional arguments *vstart*, *finish*, *ndepth*, *parity*, *zoffset* are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable *finish* is true, the computation has ended. All eigenpairs between *dol* and *dou* have been computed. *m* is set to *dou* - *dol* + 1.
- ?larrv2 needs more workspace in *z* than the sequential slarrv. It is used to store the conformal embedding of the local representation tree.

Input Parameters

n

INTEGER

The order of the matrix. $n \geq 0$.

vl, *vu*

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Lower and upper bounds of the interval that contains the desired eigenvalues. $vl < vu$. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired range. *vu* is currently not used but kept as parameter in case needed.

d

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Array of size *n*

The *n* diagonal elements of the diagonal matrix *d*. On exit, *d* is overwritten.

l

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Array of size *n*

The (*n*-1) subdiagonal elements of the unit bidiagonal matrix *L* are in elements 1 to *n*-1 of *l* (if the matrix is not split.) At the end of each block is stored the corresponding shift as given by ?larre. On exit, *l* is overwritten.

pivmin

DOUBLE PRECISION

The minimum pivot allowed in the sturm sequence.

isplit

INTEGER

Array of size *n*

The splitting points, at which *T* breaks up into blocks. The first block consists of rows/columns 1 to *isplit*(1), the second of rows/columns *isplit*(1) + 1 through *isplit*(2), etc.

m INTEGER

The total number of input eigenvalues. 0 ≤*m*≤*n*.

dol, *dou* INTEGER

If you want to compute only selected eigenvectors from all the eigenvalues supplied, you can specify an index range *dol*:*dou*. Or else the setting *dol*=1, *dou*=*m* should be applied. Note that *dol* and *dou* refer to the order in which the eigenvalues are stored in *w*. If you want to compute only selected eigenpairs, the columns *dol*-1 to *dou*+1 of the eigenvector space *z* contain the computed eigenvectors. All other columns of *z* are set to zero.

If *dol* > 1, then *z*(:,*dol*-1-*zoffset*) is used.

If *dou* < *m*, then *z*(:,*dou*+1-*zoffset*) is used.

needil, *neediu* INTEGER

Describe which are the left and right outermost eigenvalues that still need to be included in the computation. These indices indicate whether eigenvalues from other processors are needed to correctly compute the conformally embedded representation tree.

When *dol*≤*needil*≤*neediu*≤*dou*, all required eigenvalues are local to the processor and no communication is required to compute its part of the representation tree.

minrgp REAL for slarrv2

DOUBLE PRECISION for dlarrv2

The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached.

rtol1, *rtol2* REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Parameters for bisection. An interval [*left*,*right*] has converged if *right*-*left* < max(*rtol1***gap*, *rtol2**max(|*left*|,|*right*|))

w REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Array of size *n*

The first *m* elements of *w* contain the approximate eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array *w* from ?stegr2a is expected here.) Furthermore, they are with respect to the shift of the corresponding root representation for their block.

werr REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Array of size *n*

The first *m* elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in *w*.

wgap

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Array of size *n*

The separation from the right neighbor eigenvalue in *w*.

iblock

INTEGERArray of size *n*

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in *w*; *iblock*(*i*)=1 if eigenvalue *w*(*i*) belongs to the first block from the top, *iblock*(*i*)=2 if *w*(*i*) belongs to the second block, and so on.

indexw

INTEGERArray of size *n*

The indices of the eigenvalues within each block (submatrix). For example: *indexw*(*i*)= 10 and *iblock*(*i*)=2 imply that the *i*-th eigenvalue *w*(*i*) is the 10th eigenvalue in block 2.

gers

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Array of size 2**n*

The *n* Gerschgorin intervals (the *i*-th Gerschgorin interval is (*gers*(2**i*-1), *gers*(2**i*))). The Gerschgorin intervals should be computed from the original unshifted matrix.

Not used but kept as parameter for possible future use.

sdiam

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Array of size *n*

The spectral diameters for all unreduced blocks.

ldz

INTEGER

The leading dimension of the array *z*. *ldz*≥ 1, and if stegr2b parameter *jobz* = 'V', *ldz*≥ max(1,*n*).

work

REAL for slarrv2

DOUBLE PRECISION for dlarrv2

(workspace) array of size 12**n*

iwork

(workspace) INTEGERArray of size 7**n*

vstart

LOGICAL

.TRUE. on initialization, set to .FALSE. afterwards.

finish

LOGICAL

A flag that indicates whether all eigenpairs have been computed.

maxcls

INTEGER

The largest cluster worked on by this processor in the representation tree.

ndepth

INTEGER

The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.

parity INTEGER

An internal parameter needed for the storage of the clusters on the current level of the representation tree.

zoffset INTEGER

Offset for storing the eigenpairs when *z* is distributed in 1D-cyclic fashion.

OUTPUT Parameters

needil, *neediu*

w Unshifted eigenvalues for which eigenvectors have already been computed.

werr Contains refined values of its input approximations.

wgap Contains refined values of its input approximations. Very small gaps are changed.

z REAL for slarrv2

DOUBLE PRECISION for dlarrv2

Array, dimension (*ldz*, max(1,*m*))

If *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *T* corresponding to the input eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).

In the distributed version, only a subset of columns is accessed, see *dol*, *dou*, and *zoffset*.

isuppz INTEGER

Array of size 2*max(1,*m*)

The support of the eigenvectors in *z*, i.e., the indices indicating the non-zero elements in *z*. The *i*-th eigenvector is non-zero only in elements *isuppz*(2**i*-1) through *isuppz*(2**i*).

vstart .TRUE. on initialization, set to .FALSE. afterwards.

finish A flag that indicates whether all eigenpairs have been computed.

maxcls The largest cluster worked on by this processor in the representation tree.

ndepth The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.

parity An internal parameter needed for the storage of the clusters on the current level of the representation tree.

info INTEGER

= 0: successful exit

> 0: A problem occured in ?larrv2.

< 0: One of the called subroutines signaled an internal problem.

Needs inspection of the corresponding parameter *info* for further information.

=-1: Problem in ?larrb2 when refining a child's eigenvalues.

=-2: Problem in ?larrf2 when computing the RRR of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter *minrgp* smaller and recompile. However, as the orthogonality of the computed vectors is proportional to 1/*minrgp*, be aware that decreasing *minrgp* might be reduce precision.

=-3: Problem in ?larrb2 when refining a single eigenvalue after the Rayleigh correction was rejected.

= 5: The Rayleigh Quotient Iteration failed to converge to full accuracy.

Overview for details of ScaLAPACK array descriptor structures and related notations.

?lasorte

Sorts eigenpairs by real and complex data types.

Syntax

```
call slasorte(s, lds, j, out, info)
call dlasorte(s, lds, j, out, info)
```

Description

The ?lasorteroutine sorts eigenpairs so that real eigenpairs are together and complex eigenpairs are together. This helps to employ 2x2 shifts easily since every second subdiagonal is guaranteed to be zero. This routine does no parallel work and makes no calls.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Input Parameters

s (local)

REAL for slasorte

DOUBLE PRECISION for dlasorte

Array of size *lds*.

On entry, a matrix already in Schur form.

lds (local) INTEGER.

On entry, the leading dimension of the array *s*; unchanged on exit.

j (local) INTEGER.

On entry, the order of the matrix *S*; unchanged on exit.

out	(local) REAL for slasorte DOUBLE PRECISION for dlasorte Array of size 2**j*. The work buffer required by the routine.
info	(local) INTEGER. Set, if the input matrix had an odd number of real eigenvalues and things could not be paired or if the input matrix *S* was not originally in Schur form. 0 indicates successful completion.

Output Parameters

s	On exit, the diagonal blocks of *S* have been rewritten to pair the eigenvalues. The resulting matrix is no longer similar to the input.
out	Work buffer.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

?lasrt2

Sorts numbers in increasing or decreasing order.

Syntax

```
call slasrt2(id, n, d, key, info)
call dlasrt2(id, n, d, key, info)
```

Description

The ?lasrt2routine is modified LAPACK routine ?lasrt, which sorts the numbers in *d* in increasing order (if *id* = 'I') or in decreasing order (if *id* = 'D'). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20. The size of STACK limits *n* to about 2^{32}.

Input Parameters

id	CHARACTER*1. = 'I': sort *d* in increasing order; = 'D': sort *d* in decreasing order.
n	INTEGER. The length of the array *d*.
d	REAL for slasrt2 DOUBLE PRECISION for dlasrt2. Array of size *n*. On entry, the array to be sorted.
key	INTEGER. Array of size *n*. On entry, *key* contains a key to each of the entries in d().

Typically, *key*(*i*) = *i* for all *i*.

Output Parameters

d

On exit, *d* has been sorted into increasing order

(*d*(1) ≤ ... ≤ *d*(*n*))

or into decreasing order

(*d*(1) ≥ ... ≥ *d*(*n*)),

depending on *id*.

info

INTEGER.

= 0: successful exit

< 0: if *info* = -i, the *i*-th argument had an illegal value.

key

On exit, *key* is permuted in exactly the same manner as *d* was permuted from input to output. Therefore, if *key*(*i*) = *i* for all *i* on input, *d*(*i*) on output equals *d*(*key*(*i*)) on input.

?stegr2

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

```
call sstegr2( jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, isuppz, work, lwork, iwork, liwork, dol, dou, zoffset, info )
```

```
call dstegr2( jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, isuppz, work, lwork, iwork, liwork, dol, dou, zoffset, info )
```

Description

?stegr2 computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix *T*. It is invoked in the ScaLAPACK MRRR driver p?syevr and the corresponding Hermitian version either when only eigenvalues are to be computed, or when only a single processor is used (the sequential-like case).

?stegr2 has been adapted from LAPACK's ?stegr. Please note the following crucial changes.

1. The calling sequence has two additional integer parameters, *dol* and *dou*, that should satisfy *m*≥*dou*≥*dol*≥1. ?stegr2*only* computes the eigenpairs corresponding to eigenvalues *dol* through *dou* in *w*. (That is, instead of computing the eigenpairs belonging to *w*(1) through *w*(*m*), only the eigenvectors belonging to eigenvalues *w*(*dol*) through *w*(*dou*) are computed. In this case, only the eigenvalues *dol*:*dou* are guaranteed to be fully accurate.
2. *m* is *not* the number of eigenvalues specified by *range*, but is *m* = *dou* - *dol* + 1. This concerns the case where only eigenvalues are computed, but on more than one processor. Thus, in this case *m* refers to the number of eigenvalues computed on this processor.
3. The arrays *w* and *z* might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

Input Parameters

jobz

CHARACTER*1

= 'N': Compute eigenvalues only;

= 'V': Compute eigenvalues and eigenvectors.

range

CHARACTER*1

= 'A': all eigenvalues will be found.

= 'V': all eigenvalues in the half-open interval (*vl*,*vu*] will be found.

= 'I': the *il*-th through *iu*-th eigenvalues (of the entire matrix) will be found.

n

INTEGER

The order of the matrix. $n \geq 0$.

d

REAL for sstegr2

DOUBLE PRECISION for dstegr2

Array of size *n*

On entry, the *n* diagonal elements of the tridiagonal matrix *T*. Overwritten on exit.

e

REAL for sstegr2

DOUBLE PRECISION for dstegr2

Array of size *n*

On entry, the (*n*-1) subdiagonal elements of the tridiagonal matrix *T* in elements 1 to *n*-1 of *e*. *e*(*n*) need not be set on input, but is used internally as workspace. Overwritten on exit.

vl

REAL for sstegr2

DOUBLE PRECISION for dstegr2

vu

REAL for sstegr2

DOUBLE PRECISION for dstegr2

If *range*='V', the lower and upper bounds of the interval to be searched for eigenvalues. *vl* < *vu*.

Not referenced if *range* = 'A' or 'I'.

il, iu

INTEGER

If *range*='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned.

$1 \le il \le iu \le n$, if $n > 0$.

Not referenced if *range* = 'A' or 'V'.

ldz INTEGER

The leading dimension of the array *z*. $ldz \ge 1$, and if *jobz* = 'V', then $ldz \ge \max(1,n)$.

nzc INTEGER

The number of eigenvectors to be held in the array *z*, storing the matrix *Z*.

If *range* = 'A', then $nzc \ge \max(1,n)$.

If *range* = 'V', then *nzc*≥ the number of eigenvalues in (*vl*,*vu*].

If *range* = 'I', then $nzc \ge iu-il+1$.

If *nzc* = -1, then a workspace query is assumed; the routine calculates the number of columns of the matrix *Z* that are needed to hold the eigenvectors. This value is returned as the first entry of the *z* array, and no error message related to *nzc* is issued.

lwork INTEGER

The size of the array *work*. $lwork \ge \max(1,18*n)$

if *jobz* = 'V', and $lwork \ge \max(1,12*n)$ if *jobz* = 'N'. If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued.

liwork INTEGER

The size of the array *iwork*. $liwork \ge \max(1,10*n)$ if the eigenvectors are desired, and $liwork \ge \max(1,8*n)$ if only the eigenvalues are to be computed.

If *liwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued.

dol, *dou* INTEGER

From the eigenvalues *w*(1:*m*), only eigenvectors *Z*(:,*dol*) to *Z*(:,*dou*) are computed.

If *dol* > 1, then *Z*(:,*dol*-1-*zoffset*) is used and overwritten.

If *dou* < *m*, then *Z*(:,*dou*+1-*zoffset*) is used and overwritten.

zoffset INTEGER

Offset for storing the eigenpairs when *z* is distributed in 1D-cyclic fashion

OUTPUT Parameters

m INTEGER

Globally summed over all processors, *m* equals the total number of eigenvalues found. 0 ≤*m*≤*n*. If *range* = 'A', *m* = *n*, and if *range* = 'I', *m* = *iu-il*+1. The local output equals *m* = *dou* - *dol* + 1.

w

REAL array of size *n* for sstegr2

DOUBLE PRECISION array of size *n* for dstegr2

Array of size *n*

The first *m* elements contain the selected eigenvalues in ascending order. Note that immediately after exiting this routine, only the eigenvalues from position *dol*:*dou* are reliable on this processor because the eigenvalue computation is done in parallel. Other processors will hold reliable information on other parts of the *w* array. This information is communicated in the ScaLAPACK driver.

z

REAL for sstegr2

DOUBLE PRECISION for dstegr2

Array of size (*ldz*, max(1,*m*)).

If *jobz* = 'V', and if *info* = 0, then the first *m* columns of the matrix *Z* stored in *z* contain some of the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the *i*-th column of *Z* holding the eigenvector associated with *w*(*i*).

If *jobz* = 'N', then *z* is not referenced.

Note: the user must ensure that at least max(1,*m*) columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and can be computed with a workspace query by setting *nzc* = -1, see below.

isuppz

INTEGER array of size 2*max(1,*m*)

The support of the eigenvectors in *z*, i.e., the indices indicating the nonzero elements in *z*. The *i*-th computed eigenvector is nonzero only in elements *isuppz*(2**i*-1) through *isuppz*(2**i*). This is relevant in the case when the matrix is split. *isuppz* is only set if *n*>2.

work

On exit, if *info* = 0, *work*(1) returns the optimal (and minimal) *lwork*.

iwork

On exit, if *info* = 0, *iwork*(1) returns the optimal *liwork*.

info

INTEGER

On exit, *info*

= 0: successful exit

other:if *info* = -*i*, the *i*-th argument had an illegal value

if *info* = 10X, internal error in ?larre2,

if *info* = 20X, internal error in ?larrv.

Here, the digit X = ABS(*iinfo*) < 10, where *iinfo* is the nonzero error code returned by ?larre2 or ?larrv, respectively.

?stegr2a

Computes selected eigenvalues and initial representations needed for eigenvector computations.

Syntax

```
call sstegr2a( jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, work, lwork,
iwork, liwork, dol, dou, needil, neediu, inderr, nsplit, pivmin, scale, wl, wu, info )
```

```
call dstegr2a( jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, work, lwork,
iwork, liwork, dol, dou, needil, neediu, inderr, nsplit, pivmin, scale, wl, wu, info )
```

Description

?stegr2a computes selected eigenvalues and initial representations needed for eigenvector computations in ?stegr2b. It is invoked in the ScaLAPACK MRRR driver p?syevr and the corresponding Hermitian version when both eigenvalues and eigenvectors are computed in parallel on multiple processors. For this case, ?stegr2a implements the first part of the MRRR algorithm, parallel eigenvalue computation and finding the root RRR. At the end of ?stegr2a, other processors might have a part of the spectrum that is needed to continue the computation locally. Once this eigenvalue information has been received by the processor, the computation can then proceed by calling the second part of the parallel MRRR algorithm, ?stegr2b.

Please note:

- The calling sequence has two additional integer parameters, (compared to LAPACK's stegr), these are *dol* and *dou* and should satisfy $m \geq dou \geq dol \geq 1$. These parameters are only relevant for the case *jobz* = 'V'.

  Globally invoked over all processors, ?stegr2a computes all the eigenvalues specified by *range*.

  ?stegr2a locally only computes the eigenvalues corresponding to eigenvalues *dol* through *dou* in *w*. (That is, instead of computing the eigenvectors belonging to *w*(1) through *w*(*m*), only the eigenvectors belonging to eigenvalues *w*(*dol*) through *w*(*dou*) are computed. In this case, only the eigenvalues *dol*:*dou* are guaranteed to be fully accurate.
- *m* is not the number of eigenvalues specified by *range*, but it is *m* = *dou* - *dol* + 1. Instead, *m* refers to the number of eigenvalues computed on this processor.
- While no eigenvectors are computed in ?stegr2a itself (this is done later in ?stegr2b), the interface

  If *jobz* = 'V' then, depending on *range* and *dol*, *dou*, ?stegr2a might need more workspace in *z* then the original ?stegr. In particular, the arrays *w* and *z* might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

Notice revision #20201201

Input Parameters

jobz — CHARACTER*1

= 'N': Compute eigenvalues only;

= 'V': Compute eigenvalues and eigenvectors.

range — CHARACTER*1

= 'A': all eigenvalues will be found.

= 'V': all eigenvalues in the half-open interval (*vl*,*vu*] will be found.

= 'I': the *il*-th through *iu*-th eigenvalues (of the entire matrix) will be found.

n INTEGER

The order of the matrix. $n \geq 0$.

d REAL for sstegr2a

DOUBLE PRECISION for dstegr2a

Array of size *n*

The *n* diagonal elements of the tridiagonal matrix *T*. Overwritten on exit.

e REAL for sstegr2a

DOUBLE PRECISION for dstegr2a

Array of size *n*

On entry, the (*n*-1) subdiagonal elements of the tridiagonal matrix *T* in elements 1 to *n*-1 of *e*. *e*(*n*) need not be set on input, but is used internally as workspace. Overwritten on exit.

vl, *vu* REAL for sstegr2a

DOUBLE PRECISION for dstegr2a

If *range*='V', the lower and upper bounds of the interval to be searched for eigenvalues. *vl* < *vu*.

Not referenced if *range* = 'A' or 'I'.

il, *iu* INTEGER

If *range*='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq il \leq iu \leq n$, if $n > 0$.

Not referenced if *range* = 'A' or 'V'.

ldz INTEGER

The leading dimension of the array *z*. $ldz \geq 1$, and if *jobz* = 'V', then $ldz \geq \max(1,n)$.

nzc INTEGER

The number of eigenvectors to be held in the array *z*.

If *range* = 'A', then $nzc \geq \max(1,n)$.

If *range* = 'V', then *nzc*≥ the number of eigenvalues in (*vl*,*vu*].

If *range* = 'I', then $nzc \geq iu-il+1$.

If *nzc* = -1, then a workspace query is assumed; the routine calculates the number of columns of the array *z* that are needed to hold the eigenvectors. This value is returned as the first entry of the *z* array, and no error message related to *nzc* is issued.

lwork INTEGER

The size of the array *work*. *lwork*≥ max(1,18**n*) if *jobz* = 'V', and *lwork*≥ max(1,12**n*) if *jobz* = 'N'.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued.

liwork INTEGER

The size of the array *iwork*. *liwork*≥ max(1,10**n*) if the eigenvectors are desired, and *liwork*≥ max(1,8**n*) if only the eigenvalues are to be computed.

If *liwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued.

dol, *dou* INTEGER

From all the eigenvalues *w*(1:*m*), only eigenvalues *w*(*dol*:*dou*) are computed.

OUTPUT Parameters

m INTEGER

Globally summed over all processors, *m* equals the total number of eigenvalues found. 0 ≤*m*≤*n*.

If *range* = 'A', *m* = *n*, and if *range* = 'I', *m* = *iu*-*il*+1.

The local output equals *m* = *dou* - *dol* + 1.

w REAL for sstegr2a

DOUBLE PRECISION for dstegr2a

Array of size *n*

The first *m* elements contain approximations to the selected eigenvalues in ascending order. Note that immediately after exiting this routine, only the eigenvalues from position *dol*:*dou* are reliable on this processor because the eigenvalue computation is done in parallel. The other entries outside *dol*:*dou*are very crude preliminary approximations. Other processors hold reliable information on these other parts of the *w* array.

This information is communicated in the ScaLAPACK driver.

z REAL for sstegr2a

DOUBLE PRECISION for dstegr2a

Array of size (*ldz*, max(1,*m*)).

?stegr2a does not compute eigenvectors, this is done in ?stegr2b. The argument *z* as well as all related other arguments only appear to keep the interface consistent and to signal to the user that this subroutine is meant to be used when eigenvectors are computed.

work On exit, if *info* = 0, *work*(1) returns the optimal (and minimal) *lwork*.

iwork — On exit, if *info* = 0, *iwork*(1) returns the optimal *liwork*.

needil, *neediu* — INTEGER

The indices of the leftmost and rightmost eigenvalues needed to accurately compute the relevant part of the representation tree. This information can be used to find out which processors have the relevant eigenvalue information needed so that it can be communicated.

inderr — INTEGER

inderr points to the place in the work space where the eigenvalue uncertainties (errors) are stored.

nsplit — INTEGER

The number of blocks into which *T* splits. 1 ≤*nsplit*≤*n*.

pivmin — REAL for sstegr2a

DOUBLE PRECISION for dstegr2a

The minimum pivot in the sturm sequence for *T*.

scale — REAL for sstegr2a

DOUBLE PRECISION for dstegr2a

The scaling factor for the tridiagonal *T*.

wl, *wu* — REAL for sstegr2a

DOUBLE PRECISION for dstegr2a

The interval (*wl*, *wu*] contains all the wanted eigenvalues.

It is either given by the user or computed in ?larre2a.

info — INTEGER

On exit, *info* = 0: successful exit

other: if *info* = -*i*, the *i*-th argument had an illegal value

if *info* = 10*x*, internal error in ?larre2a,

Here, the digit *x* = abs(*iinfo*) < 10, where *iinfo* is the nonzero error code returned by ?larre2a.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

?stegr2b

From eigenvalues and initial representations computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors.

Syntax

```
call sstegr2b( jobz, n, d, e, m, w, z, ldz, nzc, isuppz, work, lwork, iwork, liwork, dol,
dou, needil, neediu, indwlc, pivmin, scale, wl, wu, vstart, finish, maxcls, ndepth,
parity, zoffset, info )
```

```
call dstegr2b( jobz, n, d, e, m, w, z, ldz, nzc, isuppz, work, lwork, iwork, liwork, dol,
dou, needil, neediu, indwlc, pivmin, scale, wl, wu, vstart, finish, maxcls, ndepth,
parity, zoffset, info )
```

Description

?stegr2b should only be called after a call to ?stegr2a. From eigenvalues and initial representations computed by ?stegr2a, ?stegr2b computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors. It is potentially invoked multiple times on a given processor because the locally relevant representation tree might depend on spectral information that is "owned" by other processors and might need to be communicated.

Please note:

- The calling sequence has two additional integer parameters, *dol* and *dou*, that should satisfy $m \geq dou \geq dol \geq 1$. These parameters are only relevant for the case *jobz* = 'V'. ?stegr2b only computes the eigenvectors corresponding to eigenvalues *dol* through *dou* in *w*. (That is, instead of computing the eigenvectors belonging to *w*(1) through *w*(*m*), only the eigenvectors belonging to eigenvalues *w*(*dol*) through *w*(*dou*) are computed. In this case, only the eigenvalues *dol*:*dou* are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.
- The additional arguments *vstart*, *finish*, *ndepth*, *parity*, *zoffset* are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable *finish*equals .TRUE., the computation has ended. All eigenpairs between *dol* and *dou* have been computed. *m* is set to *dou* - *dol* + 1.
- ?stegr2b needs more workspace in *z* than the sequential ?stegr. It is used to store the conformal embedding of the local representation tree.

Input Parameters

jobz

CHARACTER*1

= 'N': Compute eigenvalues only;

= 'V': Compute eigenvalues and eigenvectors.

n

INTEGER

The order of the matrix. $n \geq 0$.

d

REAL for sstegr2b

DOUBLE PRECISION for dstegr2b

Array of size *n*

The *n* diagonal elements of the tridiagonal matrix T. Overwritten on exit.

e

REAL for sstegr2b

DOUBLE PRECISION for dstegr2b

Array of size *n*

The (*n*-1) subdiagonal elements of the tridiagonal matrix *T* in elements 1 to *n*-1 of *e*. *e*(*n*) need not be set on input, but is used internally as workspace. Overwritten on exit.

m INTEGER

The total number of eigenvalues found in ?stegr2a. 0 ≤*m*≤*n*.

w REAL for sstegr2b

DOUBLE PRECISION for dstegr2b

Array of size *n*

The first *m* elements contain approximations to the selected eigenvalues in ascending order. Note that only the eigenvalues from the locally relevant part of the representation tree, that is all the clusters that include eigenvalues from *dol*:*dou*, are reliable on this processor. (It does not need to know about any others anyway.)

ldz INTEGER

The leading dimension of the array *z*. *ldz*≥ 1, and if *jobz* = 'V', then *ldz*≥ max(1,*n*).

nzc INTEGER

The number of eigenvectors to be held in the array *z*, storing the matrix *Z*.

lwork INTEGER

The size of the array *work*. *lwork*≥ max(1,18**n*)

if *jobz* = 'V', and *lwork*≥ max(1,12**n*) if *jobz* = 'N'.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued.

liwork INTEGER

The size of the array *iwork*. *liwork*≥ max(1,10**n*) if the eigenvectors are desired, and *liwork*≥ max(1,8**n*) if only the eigenvalues are to be computed.

If *liwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued.

dol, *dou* INTEGER

From the eigenvalues *w*(1:*m*), only eigenvectors *Z*(:,*dol*) to *Z*(:,*dou*) are computed.

If *dol* > 1, then *Z*(:,*dol*-1-*zoffset*) is used and overwritten.

If *dou* < *m*, then *Z*(:,*dou*+1-*zoffset*) is used and overwritten.

needil, *neediu* INTEGER

Describes which are the left and right outermost eigenvalues still to be computed. Initially computed by ?larre2a, modified in the course of the algorithm.

pivmin

REAL for sstegr2b

DOUBLE PRECISION for dstegr2b

The minimum pivot in the sturm sequence for *T*.

scale

REAL for sstegr2b

DOUBLE PRECISION for dstegr2b

The scaling factor for *T*. Used for unscaling the eigenvalues at the very end of the algorithm.

wl, *wu*

REAL for sstegr2b

DOUBLE PRECISION for dstegr2b

The interval (*wl*, *wu*] contains all the wanted eigenvalues.

vstart

LOGICAL

.TRUE. on initialization, set to .FALSE. afterwards.

finish

LOGICAL

Indicates whether all eigenpairs have been computed.

maxcls

INTEGER

The largest cluster worked on by this processor in the representation tree.

ndepth

INTEGER

The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.

parity

INTEGER

An internal parameter needed for the storage of the clusters on the current level of the representation tree.

zoffset

INTEGER

Offset for storing the eigenpairs when *z* is distributed in 1D-cyclic fashion.

OUTPUT Parameters

z

REAL for sstegr2b

DOUBLE PRECISION for dstegr2b

Array of size (*ldz*, max(1,*m*))

If *jobz* = 'V', and if *info* = 0, then a subset of the first *m* columns of the matrix *Z*, stored in *z*, contain the orthonormal eigenvectors of the matrix *T* corresponding to the selected eigenvalues, with the *i*-th column of *Z* holding the eigenvector associated with *w*(*i*).

See *dol*, *dou* for more information.

isuppz

INTEGER array of size 2*max(1,*m*).

	The support of the eigenvectors in *z*, i.e., the indices indicating the nonzero elements in *z*. The *i*-th computed eigenvector is nonzero only in elements *isuppz*(2**i*-1) through *isuppz*(2**i*). This is relevant in the case when the matrix is split. *isuppz* is only set if *n*>2.
work	On exit, if *info* = 0, *work*(1) returns the optimal (and minimal) *lwork*.
iwork	On exit, if *info* = 0, *iwork*(1) returns the optimal *liwork*.
needil, *neediu*	Modified in the course of the algorithm.

indwlc	`REAL` for `sstegr2b`
	`DOUBLE PRECISION` for `dstegr2b`
	Pointer into the workspace location where the local eigenvalue representations are stored. ("Local eigenvalues" are those relative to the individual shifts of the RRRs.)

vstart	`.TRUE.` on initialization, set to `.FALSE.` afterwards.
finish	Indicates whether all eigenpairs have been computed
maxcls	The largest cluster worked on by this processor in the representation tree.
ndepth	The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.
parity	An internal parameter needed for the storage of the clusters on the current level of the representation tree.
info	`INTEGER` On exit, *info* = 0: successful exit other:if *info* = -*i*, the *i*-th argument had an illegal value if *info* = 20*x*, internal error in `?larrv2`. Here, the digit *x* = abs(`iinfo`) < 10, where `iinfo` is the nonzero error code returned by `?larrv2`

?stein2

Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.

Syntax

```
call sstein2(n, d, e, m, w, iblock, isplit, orfac, z, ldz, work, iwork, ifail, info)
call dstein2(n, d, e, m, w, iblock, isplit, orfac, z, ldz, work, iwork, ifail, info)
```

Description

The `?stein2`routine is a modified LAPACK routine `?stein`. It computes the eigenvectors of a real symmetric tridiagonal matrix *T* corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter *maxits* (currently set to 5).

Input Parameters

n

INTEGER. The order of the matrix T ($n \geq 0$).

m

INTEGER. The number of eigenvectors to be found ($0 \leq m \leq n$).

d, *e*, *w*

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Arrays:

d(*), of size *n*. The *n* diagonal elements of the tridiagonal matrix *T*.

e(*), of size *n*.

The (*n*-1) subdiagonal elements of the tridiagonal matrix *T*, in elements 1 to *n*-1. *e*(*n*) need not be set.

w(*), of size *n*.

The first *m* elements of *w* contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array *w* from ?stebz with ORDER = 'B' is expected here).

The size of *w* must be at least max(1, *n*).

iblock

INTEGER.

Array of size *n*.

The submatrix indices associated with the corresponding eigenvalues in *w*;

iblock(*i*) = 1, if eigenvalue *w*(*i*) belongs to the first submatrix from the top,

iblock(*i*) = 2, if eigenvalue *w*(*i*) belongs to the second submatrix, etc. (The output array *iblock* from ?stebz is expected here).

isplit

INTEGER.

Array of size *n*.

The splitting points, at which *T* breaks up into submatrices. The first submatrix consists of rows/columns 1 to *isplit*(1), the second submatrix consists of rows/columns *isplit*(1)+1 through *isplit*(2), etc. (The output array *isplit* from ?stebz is expected here).

orfac

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

orfac specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues which are within *orfac**||*T*|| of each other are to be orthogonalized.

ldz

INTEGER. The leading dimension of the output array *z*; *ldz* ≥ max(1, *n*).

work

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Workspace array of size $5n$.

iwork INTEGER. Workspace array of size n.

Output Parameters

z REAL for sstein2

DOUBLE PRECISION for dstein2

Array of size *ldz* by m.

The computed eigenvectors. The eigenvector associated with the eigenvalue $w(i)$ is stored in the *i*-th column of z. Any vector that fails to converge is set to its current iterate after *maxits* iterations.

ifail INTEGER.

Array of size m.

On normal exit, all elements of *ifail* are zero. If one or more eigenvectors fail to converge after *maxits* iterations, then their indices are stored in the array *ifail*.

info INTEGER.

info = 0, the exit is successful.

info < 0: if *info* = -*i*, the *i*-th had an illegal value.

info > 0: if *info* = *i*, then *i* eigenvectors failed to converge in *maxits* iterations. Their indices are stored in the array *ifail*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

?dbtf2

Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).

Syntax

```
call sdbtf2(m, n, kl, ku, ab, ldab, info)
call ddbtf2(m, n, kl, ku, ab, ldab, info)
call cdbtf2(m, n, kl, ku, ab, ldab, info)
call zdbtf2(m, n, kl, ku, ab, ldab, info)
```

Description

The ?dbtf2routine computes an *LU* factorization of a general real/complex *m*-by-*n* band matrix *A* without using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling BLAS Routines and Functions.

Input Parameters

m INTEGER. The number of rows of the matrix *A* ($m \geq 0$).

n INTEGER. The number of columns in *A* (*n* ≥ 0).

kl INTEGER. The number of sub-diagonals within the band of *A* (*kl* ≥ 0).

ku INTEGER. The number of super-diagonals within the band of *A* (*ku* ≥ 0).

ab REAL for sdbtf2

DOUBLE PRECISION for ddbtf2

COMPLEX for cdbtf2

COMPLEX*16 for zdbtf2.

Array of size *ldab* by *n*.

The matrix *A* in band storage, in rows *kl*+1 to 2*kl*+*ku*+1; rows 1 to *kl* of the array need not be set. The *j*-th column of *A* is stored in the*j*-th column of the array *ab* as follows: *ab*(*kl*+*ku*+1+*i*-*j*,*j*) = *A*(*i*,*j*) for *max*(1,*j*-*ku*) ≤ *i* ≤ *min*(*m*,*j*+*kl*).

ldab INTEGER. The leading dimension of the array *ab*.

(*ldab* ≥ 2*kl* + *ku* +1)

Output Parameters

ab On exit, details of the factorization: *U* is stored as an upper triangular band matrix with *kl*+*ku* superdiagonals in rows 1 to *kl*+*ku*+1, and the multipliers used during the factorization are stored in rows *kl*+*ku*+2 to 2**kl*+*ku*+1. See the *Application Notes* below for further details.

info INTEGER.

= 0: successful exit

< 0: if *info* = - *i*, the *i*-th argument had an illegal value,

> 0: if *info* = + *i*, *U*(*i*,*i*) is 0. The factorization has been completed, but the factor *U* is exactly singular. Division by 0 will occur if you use the factor *U* for solving a system of linear equations.

Application Notes

The band storage scheme is illustrated by the following example, when *m* = *n* = 6, *kl* = 2, *ku* = 1:

on entry

$$\begin{bmatrix} * & a12 & a23 & a34 & a45 & a56 \\ a11 & a22 & a33 & a44 & a55 & a66 \\ a21 & a32 & a43 & a54 & a65 & * \\ a31 & a42 & a53 & a64 & * & * \end{bmatrix}$$

on exit

$$\begin{bmatrix} * & u12 & u23 & u34 & u45 \\ u11 & u22 & u33 & u44 & u55 \\ m21 & m32 & m43 & m54 & m65 \\ m31 & m42 & m53 & m64 & * \end{bmatrix}$$

The routine does not use array elements marked *; elements marked + need not be set on entry, but the routine requires them to store elements of *U*, because of fill-in resulting from the row interchanges.

Overview for details of ScaLAPACK array descriptor structures and related notations.

?dbtrf

Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm).

Syntax

```
call sdbtrf(m, n, kl, ku, ab, ldab, info)
call ddbtrf(m, n, kl, ku, ab, ldab, info)
call cdbtrf(m, n, kl, ku, ab, ldab, info)
call zdbtrf(m, n, kl, ku, ab, ldab, info)
```

Description

This routine computes an LU factorization of a real *m*-by-*n* band matrix *A* without using partial pivoting or row interchanges.

This is the blocked version of the algorithm, calling BLAS Routines and Functions.

Input Parameters

m	INTEGER. The number of rows of the matrix *A* ($m \geq 0$).
n	INTEGER. The number of columns in *A* ($n \geq 0$).
kl	INTEGER. The number of sub-diagonals within the band of *A* ($kl \geq 0$).
ku	INTEGER. The number of super-diagonals within the band of *A* ($ku \geq 0$).
ab	REAL for sdbtrf DOUBLE PRECISION for ddbtrf COMPLEX for cdbtrf COMPLEX*16 for zdbtrf. Array of size *ldab* by *n*. The matrix *A* in band storage, in rows *kl*+1 to 2*kl*+*ku*+1; rows 1 to *kl* of the array need not be set. The *j*-th column of *A* is stored in the *j*-th column of the array *ab* as follows: *ab*(*kl*+*ku*+1+*i*–*j*,*j*) = *A*(*i*,*j*) for max(1,*j*–*ku*) ≤ *i* ≤ min(*m*,*j*+*kl*).
ldab	INTEGER. The leading dimension of the array *ab*. (*ldab* ≥ 2*kl* + *ku* +1)

Output Parameters

ab	On exit, details of the factorization: *U* is stored as an upper triangular band matrix with *kl*+*ku* superdiagonals in rows 1 to *kl*+*ku*+1, and the multipliers used during the factorization are stored in rows *kl*+*ku*+2 to 2**kl*+*ku*+1. See the *Application Notes* below for further details.
info	INTEGER. = 0: successful exit < 0: if *info* = - *i*, the *i*-th argument had an illegal value,

> 0: if *info* = + *i*, *U*(*i*,*i*) is 0. The factorization has been completed, but the factor *U* is exactly singular. Division by 0 will occur if you use the factor *U* for solving a system of linear equations.

Application Notes

The band storage scheme is illustrated by the following example, when *m* = *n* = 6, *kl* = 2, *ku* = 1:

on entry

$$\begin{bmatrix} * & a12 & a23 & a34 & a45 & a56 \\ a11 & a22 & a33 & a44 & a55 & a66 \\ a21 & a32 & a43 & a54 & a65 & * \\ a31 & a42 & a53 & a64 & * & * \end{bmatrix}$$

on exit

$$\begin{bmatrix} * & u12 & u23 & u34 & u45 \\ u11 & u22 & u33 & u44 & u55 \\ m21 & m32 & m43 & m54 & m65 \\ m31 & m42 & m53 & m64 & * \end{bmatrix}$$

The routine does not use array elements marked *.

?dttrf

Computes an LU factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).

Syntax

```
call sdttrf(n, dl, d, du, info)
call ddttrf(n, dl, d, du, info)
call cdttrf(n, dl, d, du, info)
call zdttrf(n, dl, d, du, info)
```

Description

The ?dttrfroutine computes an *LU* factorization of a real or complex tridiagonal matrix *A* using elimination without partial pivoting.

The factorization has the form *A* = *L***U*, where *L* is a product of unit lower bidiagonal matrices and *U* is upper triangular with nonzeros only in the main diagonal and first superdiagonal.

Input Parameters

n

INTEGER. The order of the matrix *A* (*n* ≥ 0).

dl, *d*, *du*

REAL for sdttrf

DOUBLE PRECISION for ddttrf

COMPLEX for cdttrf

COMPLEX*16 for zdttrf.

Arrays containing elements of *A*.

The array *dl* of size (*n*–1) contains the sub-diagonal elements of *A*.

The array *d* of size *n* contains the diagonal elements of *A*.

The array *du* of size (*n*-1) contains the super-diagonal elements of *A*.

Output Parameters

dl — Overwritten by the (*n*-1) multipliers that define the matrix *L* from the *LU* factorization of *A*.

d — Overwritten by the *n* diagonal elements of the upper triangular matrix *U* from the *LU* factorization of *A*.

du — Overwritten by the (*n*-1) elements of the first super-diagonal of *U*.

info — INTEGER.

= 0: successful exit

< 0: if *info* = - *i*, the *i*-th argument had an illegal value,

> 0: if *info* = *i*, *U*(*i*,*i*) is exactly 0. The factorization has been completed, but the factor *U* is exactly singular. Division by 0 will occur if you use the factor *U* for solving a system of linear equations.

Overview for details of ScaLAPACK array descriptor structures and related notations.

?dttrsv

Solves a general tridiagonal system of linear equations using the LU factorization computed by ?dttrf.

Syntax

```
call sdttrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call ddttrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call cdttrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call zdttrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
```

Description

The ?dttrsvroutine solves one of the following systems of linear equations:

$L*X = B$, $L^T*X = B$, or $L^H*X = B$,

$U*X = B$, $U^T*X = B$, or $U^H*X = B$

with factors of the tridiagonal matrix *A* from the *LU* factorization computed by ?dttrf.

Input Parameters

uplo — CHARACTER*1.

Specifies whether to solve with *L* or *U*.

trans — CHARACTER. Must be 'N' or 'T' or 'C'.

Indicates the form of the equations:

If *trans* = 'N', then $A*X=B$ is solved for *X* (no transpose).

If *trans* = 'T', then $A^T*X = B$ is solved for *X* (transpose).

	If *trans* = 'C', then $A^H*X = B$ is solved for *X* (conjugate transpose).
n	INTEGER. The order of the matrix *A* (*n* ≥ 0).
nrhs	INTEGER. The number of right-hand sides, that is, the number of columns in the matrix *B* (*nrhs* ≥ 0).
dl,*d*,*du*,*b*	REAL for sdttrsv DOUBLE PRECISION for ddttrsv COMPLEX for cdttrsv COMPLEX*16 for zdttrsv. The array *dl* of size (*n* - 1) contains the (*n* - 1) multipliers that define the matrix *L* from the *LU* factorization of *A*. The array *d* of size *n* contains *n* diagonal elements of the upper triangular matrix *U* from the *LU* factorization of *A*. The array *du* of size (*n* - 1) contains the (*n* - 1) elements of the first super-diagonal of *U*. On entry, the array *b* of size (*ldb*,*nrhs*) contains the right-hand side of matrix *B*.
ldb	INTEGER. The leading dimension of the array *b*; *ldb* ≥ max(1, *n*).

Output Parameters

b	Overwritten by the solution matrix *X*.
info	INTEGER. If *info*=0, the execution is successful. If *info* = -*i*, the *i*-th parameter had an illegal value.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

?pttrsv

*Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the L*D*L^H factorization computed by* ?pttrf.

Syntax

```
call spttrsv(trans, n, nrhs, d, e, b, ldb, info)
call dpttrsv(trans, n, nrhs, d, e, b, ldb, info)
call cpttrsv(uplo, trans, n, nrhs, d, e, b, ldb, info)
call zpttrsv(uplo, trans, n, nrhs, d, e, b, ldb, info)
```

Description

The ?pttrsvroutine solves one of the triangular systems:

$L^T*X = B$, or $L*X = B$ for real flavors,

or

$L*X = B$, or $L^H*X = B$,

*U*X = B*, or $U^H*X = B$ for complex flavors,

where *L* (or *U* for complex flavors) is the Cholesky factor of a Hermitian positive-definite tridiagonal matrix *A* such that

$A = L*D*L^H$ (computed by spttrf/dpttrf)

or

$A = U^H*D*U$ or $A = L*D*L^H$ (computed by cpttrf/zpttrf).

Input Parameters

uplo

CHARACTER*1. Must be 'U' or 'L'.

Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix *A* is stored and the form of the factorization:

If *uplo* = 'U', *e* is the superdiagonal of *U*, and $A = U^H*D*U$ or $A = L*D*L^H$;

if *uplo* = 'L', *e* is the subdiagonal of *L*, and $A = L*D*L^H$.

The two forms are equivalent, if *A* is real.

trans

CHARACTER.

Specifies the form of the system of equations:

for real flavors:

if *trans* = 'N': *L*X = B* (no transpose)

if *trans* = 'T': $L^T*X = B$ (transpose)

for complex flavors:

if *trans* = 'N': *U*X = B* or *L*X = B* (no transpose)

if *trans* = 'C': $U^H*X = B$ or $L^H*X = B$ (conjugate transpose).

n

INTEGER. The order of the tridiagonal matrix *A*. $n \geq 0$.

nrhs

INTEGER. The number of right hand sides, that is, the number of columns of the matrix *B*. $nrhs \geq 0$.

d

REAL array of size *n*. The *n* diagonal elements of the diagonal matrix *D* from the factorization computed by ?pttrf.

e

COMPLEX array of size (*n*–1). The (*n*-1) off-diagonal elements of the unit bidiagonal factor *U* or *L* from the factorization computed by ?pttrf. See *uplo*.

b

COMPLEX array of size *ldb*by *nrhs*.

On entry, the right hand side matrix *B*.

ldb

INTEGER.

The leading dimension of the array *b*.

$ldb \geq \max(1, n)$.

Output Parameters

b	On exit, the solution matrix *X*.
info	INTEGER. = 0: successful exit < 0: if *info* = -*i*, the *i*-th argument had an illegal value.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

?steqr2

Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

Syntax

```
call ssteqr2(compz, n, d, e, z, ldz, nr, work, info)
call dsteqr2(compz, n, d, e, z, ldz, nr, work, info)
```

Description

The ?steqr2routine is a modified version of LAPACK routine ?steqr. The ?steqr2routine computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. ?steqr2 is modified from ?steqr to allow each ScaLAPACK process running ?steqr2 to perform updates on a distributed matrix Q. Proper usage of ?steqr2 can be gleaned from examination of ScaLAPACK routine p?syev.

Input Parameters

compz	CHARACTER*1. Must be 'N' or 'I'. If *compz* = 'N', the routine computes eigenvalues only. If *compz* = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix *T*. *z* must be initialized to the identity matrix by p?laset or ?laset prior to entering this subroutine.
n	INTEGER. The order of the matrix *T* (*n* ≥ 0).
d, *e*, *work*	REAL for ssteqr2 DOUBLE PRECISION for dsteqr2 Arrays: *d* contains the diagonal elements of *T*. The size of *d* must be at least max(1, *n*). *e* contains the (*n*-1) subdiagonal elements of *T*. The size of *e* must be at least max(1, *n*-1). *work* is a workspace array. The size of *work* is max(1, 2*n-2). If *compz* = 'N', then *work* is not referenced.
z	(local)

REAL for ssteqr2

DOUBLE PRECISION for dsteqr2

Array of global size *n*by *n* and of local size *ldz*by *nr*.

If *compz* = 'V', then *z* contains the orthogonal matrix used in the reduction to tridiagonal form.

ldz INTEGER. The leading dimension of the array *z*. Constraints:

ldz ≥ 1,

ldz ≥ max(1, *n*), if eigenvectors are desired.

nr INTEGER. *nr* = max(1, *numroc*(*n*, *nb*, *myprow*, 0, *nprocs*)).

If *compz* = 'N', then *nr* is not referenced.

Output Parameters

d On exit, the eigenvalues in ascending order, if *info* = 0.

See also *info*.

e On exit, *e* has been destroyed.

z On exit, if *info* = 0, then,

if *compz* = 'V', *z* contains the orthonormal eigenvectors of the original symmetric matrix, and if *compz* = 'I', *z* contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If *compz* = 'N', then *z* is not referenced.

info INTEGER.

info = 0, the exit is successful.

info < 0: if *info* = -*i*, the *i*-th had an illegal value.

info > 0: the algorithm has failed to find all the eigenvalues in a total of 30*n* iterations;

if *info* = *i*, then *i* elements of *e* have not converged to zero; on exit, *d* and *e* contain the elements of a symmetric tridiagonal matrix, which is orthogonally similar to the original matrix.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

?trmvt

Performs matrix-vector operations.

Syntax

```
call strmvt (uplo, n, t, ldt, x, incx, y, incy, w, incw, z, incz )
call dtrmvt (uplo, n, t, ldt, x, incx, y, incy, w, incw, z, incz )
call ctrmvt (uplo, n, t, ldt, x, incx, y, incy, w, incw, z, incz )
call ztrmvt (uplo, n, t, ldt, x, incx, y, incy, w, incw, z, incz )
```

Description

?trmvt performs the matrix-vector operations as follows:

strmvt and dtrmvt: x := *T*' *y, and w := *T* *z

ctrmvt and ztrmvt: x := conjg(*T*') *y, and w := *T* *z,

where x is an *n* element vector and *T* is an *n*-by-*n* upper or lower triangular matrix.

Input Parameters

uplo

CHARACTER*1.

On entry, *uplo* specifies whether the matrix is an upper or lower triangular matrix as follows:

uplo = 'U' or 'u'

A is an upper triangular matrix.

uplo = 'L' or 'l'

A is a lower triangular matrix.

Unchanged on exit.

n

INTEGER.

On entry, *n* specifies the order of the matrix *A*. *n* must be at least zero.

Unchanged on exit.

t

REAL for strmvt

DOUBLE PRECISION for dtrmvt

COMPLEX for ctrmvt

DOUBLE COMPLEX for ztrmvt

Array of size (*ldt*, *n*).

Before entry with *uplo* = 'U' or 'u', the leading *n*-by-*n* upper triangular part of the array *t* must contain the upper triangular matrix and the strictly lower triangular part of *t* is not referenced.

Before entry with *uplo* = 'L' or 'l', the leading *n*-by-*n* lower triangular part of the array *t* must contain the lower triangular matrix and the strictly upper triangular part of *t* is not referenced.

ldt

INTEGER.

On entry, *lda* specifies the first dimension of *A* as declared in the calling (sub) program. *lda* must be at least max(1, *n*).

Unchanged on exit.

incx

INTEGER.

On entry, *incx* specifies the increment for the elements of *x*. *incx* must not be zero.

Unchanged on exit.

y

REAL for strmvt

DOUBLE PRECISION for dtrmvt

COMPLEX for ctrmvt

DOUBLE COMPLEX for ztrmvt

Array of size at least (1 + (*n* - 1)*abs(*incy*)).

Before entry, the incremented array *y* must contain the *n* element vector *y*.

Unchanged on exit.

incy INTEGER.

On entry, *incy* specifies the increment for the elements of *y*. *incy* must not be zero.

Unchanged on exit.

incw INTEGER.

On entry, *incw* specifies the increment for the elements of *w*. *incw* must not be zero.

Unchanged on exit.

z REAL for strmvt

DOUBLE PRECISION for dtrmvt

COMPLEX for ctrmvt

DOUBLE COMPLEX for ztrmvt

Array of size at least (1 + (*n* - 1)*abs(*incz*)).

Before entry, the incremented array *z* must contain the *n* element vector *z*.

Unchanged on exit.

incz INTEGER.

On entry, *incz* specifies the increment for the elements of *z*. *incz* must not be zero.

Unchanged on exit.

Output Parameters

t Before entry with *uplo* = 'U' or 'u', the leading *n*-by-*n* upper triangular part of the array *t* must contain the upper triangular matrix and the strictly lower triangular part of *t* is not referenced.

Before entry with *uplo* = 'L' or 'l', the leading *n*-by-*n* lower triangular part of the array *t* must contain the lower triangular matrix and the strictly upper triangular part of *t* is not referenced.

x REAL for strmvt

DOUBLE PRECISION for dtrmvt

COMPLEX for ctrmvt

DOUBLE COMPLEX for ztrmvt

Array of size at least (1 + (*n* - 1)*abs(*incx*)).

On exit, *x* = *T*' * *y*.

w

REAL for strmvt

DOUBLE PRECISION for dtrmvt

COMPLEX for ctrmvt

DOUBLE COMPLEX for ztrmvt

Array of size at least (1 + (*n* - 1)*abs(*incw*)).

On exit, *w* = *T* * *z*.

pilaenv

Returns the positive integer value of the logical blocking size.

Syntax

```
value = pilaenv (ictxt, prec )
```

Include Files

- mkl_pblas.h

Description

pilaenv returns the positive integer value of the logical blocking size. This value is machine and precision specific. This version provides a logical blocking size which should give good though not optimal performance on many of the currently available distributed-memory concurrent computers. You are encouraged to modify this subroutine to set this tuning parameter for your particular machine.

Input Parameters

ictxt

INTEGER. On entry, *ictxt* specifies the BLACS context handle, indicating the global context of the operation. The context itself is global, but the value of *ictxt* is local.

prec

CHARACTER*1. On input, *prec* specifies the precision for which the logical block size should be returned as follows:

prec = 'S' or 's' single precision real,

prec = 'D' or 'd' double precision real,

prec = 'C' or 'c' single precision complex,

prec = 'Z' or 'z' double precision complex,

prec = 'I' or 'i' integer.

Application Notes

Before modifying this routine to tune the library performance on your system, be aware of the following:

1. The value this function returns must be strictly larger than zero,
2. If you are planning to link your program with different instances of the library (for example, on a heterogeneous machine), you *must* compile each instance of the library with exactly the same version of this routine for obvious interoperability reasons.

pilaenvx

Called from the ScaLAPACK routines to choose problem-dependent parameters for the local environment.

Syntax

```
result = pilaenvx (ictxt, ispec, name, opts, n1, n2, n3, n4 )
```

Include Files

- mkl.fi

Description

pilaenvx is called from the ScaLAPACK routines to choose problem-dependent parameters for the local environment. See *ispec* for a description of the parameters. This version provides a set of parameters which should give good, though not optimal, performance on many of the currently available computers. You are encouraged to modify this subroutine to set the tuning parameters for your particular machine using the option and problem size information in the arguments.

Input Parameters

ictxt

(local input) INTEGER. On entry, *ictxt* specifies the BLACS context handle, indicating the global context of the operation. The context itself is global, but the value of *ictxt* is local.

ispec

(global input) INTEGER.

Specifies the parameter to be returned as the value of pilaenvx.

= 1: the optimal blocksize; if this value is 1, an unblocked algorithm will give the best performance (unlikely).

= 2: the minimum block size for which the block routine should be used; if the usable block size is less than this value, an unblocked routine should be used.

= 3: the crossover point (in a block routine, for N less than this value, an unblocked routine should be used).

= 4: the number of shifts, used in the nonsymmetric eigenvalue routines (DEPRECATED).

= 5: the minimum column dimension for blocking to be used; rectangular blocks must have dimension at least *k* by *m*, where *k* is given by pilaenvx(2,...) and *m* by pilaenvx(5,...).

= 6: the crossover point for the SVD (when reducing an *m* by *n* matrix to bidiagonal form, if max(*m*,*n*)/min(*m*,*n*) exceeds this value, a QR factorization is used first to reduce the matrix to a triangular form).

= 7: the number of processors.

= 8: the crossover point for the multishift QR method for nonsymmetric eigenvalue problems (DEPRECATED).

= 9: maximum size of the subproblems at the bottom of the computation tree in the divide-and-conquer algorithm (used by ?gelsd and ?gesdd).

=10: IEEE NaN arithmetic can be trusted not to trap.

=11: infinity arithmetic can be trusted not to trap.

	12 <= *ispec* <= 16: `p?hseqr` or one of its subroutines, see `piparmq` for detailed explanation. 17 <= *ispec* <= 22: Parameters for `pb?trord`/`p?hseqr` (not all), as follows: =17: maximum number of concurrent computational windows; =18: number of eigenvalues/bulges in each window; =19: computational window size; =20: minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; =21: width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; =22: the maximum number of eigenvalues moved together over a process border; =23: the number of processors involved in Aggressive Early Deflation (AED); =99: Maximum iteration chunksize in OpenMP parallelization.
name	(global input) CHARACTER*(*). The name of the calling subroutine, in either upper case or lower case.
opts	(global input) CHARACTER*(*). The character options to the subroutine name, concatenated into a single character string. For example, *uplo* = 'U', *trans* = 'T', and *diag* = 'N' for a triangular routine would be specified as *opts* = 'UTN'.
n1, *n2*, *n3*, and *n4*	(global input) INTEGER. Problem dimensions for the subroutine name; these may not all be required.

Output Parameters

result	(global output) INTEGER. >= 0: the value of the parameter specified by *ispec*. < 0: if `pilaenvx` = -*k*, the *k*-th argument had an illegal value.

Application Notes

The following conventions have been used when calling `ilaenv` from the LAPACK routines:

1. *opts* is a concatenation of all of the character options to subroutine name, in the same order that they appear in the argument list for name, even if they are not used in determining the value of the parameter specified by *ispec*.
2. The problem dimensions *n1*, *n2*, *n3*, and *n4* are specified in the order that they appear in the argument list for *name*. *n1* is used first, *n2* second, and so on, and unused problem dimensions are passed a value of -1.
3. The parameter value returned by `ilaenv` is checked for validity in the calling subroutine. For example, `ilaenv` is used to retrieve the optimal block size for `strtri` as follows:

```
NB = ilaenv( 1, 'STRTRI', UPLO // DIAG, N, -1, -1, -1 )
   IF( NB.LE.1 ) NB = MAX( 1, N )
```

The same conventions hold for this ScaLAPACK-style variant.

pjlaenv

Called from the ScaLAPACK symmetric and Hermitian tailored eigen-routines to choose problem-dependent parameters for the local environment.

Syntax

```
result = pjlaenv (ictxt, ispec, name, opts, n1, n2, n3, n4 )
```

Include Files

- mkl.fi

Description

`pjlaenv` is called from the ScaLAPACK symmetric and Hermitian tailored eigen-routines to choose problem-dependent parameters for the local environment. See *ispec* for a description of the parameters. This version provides a set of parameters which should give good, though not optimal, performance on many of the currently available computers. You are encouraged to modify this subroutine to set the tuning parameters for your particular machine using the option and problem size information in the arguments.

Input Parameters

ispec
(global input) INTEGER. Specifies the parameter to be returned as the value of `pjlaenv`.

= 1: the data layout blocksize;

= 2: the panel blocking factor;

= 3: the algorithmic blocking factor;

= 4: execution path control;

= 5: maximum size for direct call to the LAPACK routine.

name
(global input) CHARACTER*(*). The name of the calling subroutine, in either upper case or lower case.

opts
(global input) CHARACTER*(*). The character options to the subroutine name, concatenated into a single character string. For example, *uplo* = `'U'`, *trans* = `'T'`, and *diag* = `'N'` for a triangular routine would be specified as *opts* = `'UTN'`.

n1, *n2*, *n3*, and *n4*
(global input) INTEGER. Problem dimensions for the subroutine name; these may not all be required. At present, only *n1* is used, and it (*n1*) is used only for `'TTRD'`.

Output Parameters

result
(global or local output) INTEGER.

>= 0: the value of the parameter specified by *ispec*.

< 0: if `pjlaenv` = -*k*, the *k*-th argument had an illegal value. Most parameters set via a call to `pjlaenv` must be identical on all processors and hence `pjlaenv` will return the same value to all

procesors (i.e. global output). However some, in particular, the panel blocking factor can be different on each processor and hence pjlaenv can return different values on different processors (i.e. local output).

Application Notes

The following conventions have been used when calling pjlaenv from the ScaLAPACK routines:

1. *opts* is a concatenation of all of the character options to subroutine name, in the same order that they appear in the argument list for name, even if they are not used in determining the value of the parameter specified by *ispec*.
2. The problem dimensions *n1*, *n2*, *n3*, and *n4* are specified in the order that they appear in the argument list for name. *n1* is used first, *n2* second, and so on, and unused problem dimensions are passed a value of -1.
   a. The parameter value returned by pjlaenv is checked for validity in the calling subroutine. For example, pjlaenv is used to retrieve the optimal blocksize for STRTRI as follows:

```
NB = pjlaenv( 1, 'STRTRI', UPLO // DIAG, N, -1, -1, -1 )
IF( NB.LE.1 ) NB = MAX( 1, N )
```

pjlaenv is patterned after ilaenv and keeps the same interface in anticipation of future needs, even though pjlaenv is only sparsely used at present in ScaLAPACK. Most ScaLAPACK codes use the input data layout blocking factor as the algorithmic blocking factor - hence there is no need or opportunity to set the algorithmic or data decomposition blocking factor. pXYYtevx.f and pXYYtgvx.f and pXYYttrd.f are the only codes which call pjlaenv. pXYYtevx.f and pXYYtgvx.f redistribute the data to the best data layout for each transformation. pXYYttrd.f uses a data layout blocking factor of 1.

ScaLAPACK Utility Functions and Routines

This section describes ScaLAPACK utility functions and routines. Summary information about these routines is given in the following table:

ScaLAPACK Utility Functions and Routines

Routine Name	Data Types	Description
p?labad	s,d	Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.
p?lachkieee	s,d	Performs a simple check for the features of the IEEE standard. (C interface function).
p?lamch	s,d	Determines machine parameters for floating-point arithmetic.
p?lasnbt	s,d	Computes the position of the sign bit of a floating-point number. (C interface function).
descinit	N/A	Initializes the array descriptor for distributed matrix.
numroc	N/A	Computes the number of rows or columns of a distributed matrix owned by the process.

See Also

pxerbla Error handling routine called by ScaLAPACK routines.

p?labad

Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

Syntax

```
call pslabad(ictxt, small, large)
call pdlabad(ictxt, small, large)
```

Description

The p?labadroutine takes as input the values computed by p?lamch for underflow and overflow, and returns the square root of each of these values if the log of *large* is sufficiently large. This subroutine is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by p?lamch. This subroutine is needed because p?lamch does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

In addition, this routine performs a global minimization and maximization on these values, to support heterogeneous computing networks.

Input Parameters

ictxt (global) INTEGER.

The BLACS context handle in which the computation takes place.

small (local).

REAL PRECISION for pslabad.

DOUBLE PRECISION for pdlabad.

On entry, the underflow threshold as computed by p?lamch.

large (local).

REAL PRECISION for pslabad.

DOUBLE PRECISION for pdlabad.

On entry, the overflow threshold as computed by p?lamch.

Output Parameters

small (local).

On exit, if *log10*(*large*) is sufficiently large, the square root of *small*, otherwise unchanged.

large (local).

On exit, if *log10*(*large*) is sufficiently large, the square root of *large*, otherwise unchanged.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lachkieee

Performs a simple check for the features of the IEEE standard. (C interface function).

Syntax

```
void pslachkieee(int *isieee, float *rmax, float *rmin);
void pdlachkieee(int *isieee, float *rmax, float *rmin);
```

Description

The p?lachkieeeroutine performs a simple check to make sure that the features of the IEEE standard are implemented. In some implementations, p?lachkieee may not return.

Note that all arguments are call-by-reference so that this routine can be directly called from Fortran code.

This is a ScaLAPACK internal subroutine and arguments are not checked for unreasonable values.

Input Parameters

rmax (local).

`REAL` for `pslachkieee`

`DOUBLE PRECISION` for `pdlachkieee`

The overflow threshold `(= ?lamch ('O'))`.

rmin (local).

`REAL` for `pslachkieee`

`DOUBLE PRECISION` for `pdlachkieee`

The underflow threshold `(= ?lamch ('U'))`.

Output Parameters

isieee (local). `INTEGER`.

On exit, *isieee* `= 1` implies that all the features of the IEEE standard that we rely on are implemented. On exit, *isieee* `= 0` implies that some the features of the IEEE standard that we rely on are missing.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lamch

Determines machine parameters for floating-point arithmetic.

Syntax

val `= pslamch(`*ictxt*`, `*cmach*`)`

val `= pdlamch(`*ictxt*`, `*cmach*`)`

Description

The `p?lamch`routine determines single precision machine parameters.

Input Parameters

ictxt (global). `INTEGER`. The BLACS context handle in which the computation takes place.

cmach (global) `CHARACTER*1`.

Specifies the value to be returned by `p?lamch`:

`= 'E'` or `'e'`, `p?lamch := eps`

`= 'S'` or `'s'` , `p?lamch := sfmin`

`= 'B'` or `'b'`, `p?lamch := base`

`= 'P'` or `'p'`, `p?lamch := eps*base`

= 'N' or 'n', p?lamch := t

= 'R' or 'r', p?lamch := rnd

= 'M' or 'm', p?lamch := emin

= 'U' or 'u', p?lamch := rmin

= 'L' or 'l', p?lamch := emax

= 'O' or 'o', p?lamch := rmax,

where

eps = relative machine precision

sfmin = safe minimum, such that 1/sfmin does not overflow

base = base of the machine

prec = eps*base

t = number of (base) digits in the mantissa

rnd = 1.0 when rounding occurs in addition, 0.0 otherwise

emin = minimum exponent before (gradual) underflow

rmin = underflow threshold - $base^{(emin-1)}$

emax = largest exponent before overflow

rmax = overflow threshold - $(base^{emax})*(1-eps)$

Output Parameters

val	Value returned by the routine.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lasnbt

Computes the position of the sign bit of a floating-point number. (C interface function).

Syntax

```
void pslasnbt(int *ieflag);
void pdlasnbt(int *ieflag);
```

Description

The p?lasnbtroutine finds the position of the signbit of a single/double precision floating point number. This routine assumes IEEE arithmetic, and hence, tests only the 32-nd bit (for single precision) or 32-nd and 64-th bits (for double precision) as a possibility for the signbit. sizeof(int) is assumed equal to 4 bytes.

If a compile time flag (NO_IEEE) indicates that the machine does not have IEEE arithmetic, *ieflag* = 0 is returned.

Output Parameters

ieflag	INTEGER.

This flag indicates the position of the signbit of any single/double precision floating point number.

ieflag = 0, if the compile time flag NO_IEEE indicates that the machine does not have IEEE arithmetic, or if sizeof(int) is different from 4 bytes.

ieflag = 1 indicates that the signbit is the 32-nd bit for a single precision routine.

In the case of a double precision routine:

ieflag = 1 indicates that the signbit is the 32-nd bit (Big Endian).

ieflag = 2 indicates that the signbit is the 64-th bit (Little Endian).

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

descinit

Initializes the array descriptor for distributed matrix.

Syntax

```
call descinit( desc, m, n, mb, nb, irsrc, icsrc, ictxt, lld, info )
```

Description

The descintroutine initializes the array descriptor for distributed matrix.

Input Parameters

desc (global) INTEGER. array of dimension DLEN_. The array descriptor of a distributed matrix to be set.

m (global input)INTEGER. The number of rows in the distributed matrix. M >=0.

n (global input) INTEGER. The number of columns in the distributed matrix. N >=0.

mb (global input) INTEGER. The blocking factor used to distribute the rows of the matrix. MB >= 1.

nb (global input) INTEGER.INTEGER. The blocking factor used to distribute the columns of the matrix. NB >= 1.

lrsrc (global input) INTEGER. The process row over which the first row of the matrix is distributed. 0 <= IRSRC < NPROW.

lcsrc (global input) INTEGER. The process column over which the first column of the matrix is distributed. 0 <= ICSRC < NPCOL.

ictxt (global input) INTEGER. The BLACS context handle, indicating the global context of the operation on the matrix. The context itself is global.

lld (local input) INTEGER. The leading dimension of the local array storing the local blocks of the distributed matrix. LLD >= MAX(1,LOCr(M)). LOCr() denotes the number of rows of a global dense matrix that the process in a grid receives after data distributing.

Output Parameters

info	(output)INTEGER. = 0: successful exit < 0: if INFO = -i, the i-th argument had an illegal value

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

numroc

Computes the number of rows or columns of a distributed matrix owned by the process.

Syntax

```
val = numroc( n, nb, iproc, srcproc, nprocs )
```

Description

The numrocroutine computes the number of rows or columns of a distributed matrix owned by the process.

Input Parameters

n	(global input)INTEGER. The number of rows/columns in distributed matrix.
nb	(global input)INTEGER. Block size, size of the blocks the distributed matrix is split into.
iproc	(local input)INTEGER. The coordinate of the process whose local array row or column is to be determined.
srcproc	(global input)INTEGER. The coordinate of the process that possesses the first row or column of the distributed matrix.
nprocs	(global input)INTEGER. The total number processes over which the matrix is distributed.

Output Parameters

info	(output)INTEGER. Value returned by the function.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

ScaLAPACK Redistribution/Copy Routines

This section describes ScaLAPACK redistribution/copy routines. Summary information about these routines is given in the following table:

ScaLAPACK Redistribution/Copy Routines

Routine Name	Data Types	Description
p?gemr2d	s,d,c,z,i	Copies a submatrix from one general rectangular matrix to another.
p?trmr2d	s,d,c,z,i	Copies a submatrix from one trapezoidal matrix to another.

See Also

pxerbla Error handling routine called by ScaLAPACK routines.

p?gemr2d

Copies a submatrix from one general rectangular matrix to another.

Syntax

```
call psgemr2d(m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pdgemr2d(m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pcgemr2d(m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pzgemr2d(m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pigemr2d(m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
```

Description

The p?gemr2droutine copies the indicated matrix or submatrix of *A* to the indicated matrix or submatrix of *B*. It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With p?trmr2d, these routines are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix *A* in context *A* (distributed over process grid *A*) and copy it to a matrix or submatrix *B* in context *B* (distributed over process grid *B*).

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context *A* is disjoint from context *B*. The general rules for which parameters need to be set are:

- All calling processes must have the correct *m* and *n*.
- Processes in context *A* must correctly define all parameters describing *A*.
- Processes in context *B* must correctly define all parameters describing *B*.
- Processes which are not members of context *A* must pass *ctxt_a* = -1 and need not set other parameters describing *A*.
- Processes which are not members of context*B* must pass *ctxt_b* = -1 and need not set other parameters describing *B*.

Because of its generality, p?gemr2d can be used for many operations not usually associated with copy routines. For instance, it can be used to a take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for instance, this routine can be used to move the matrix from the workstation to the supercomputer and back. In ScaLAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this routine requires an array descriptor with *dtype_* = 1.

Input Parameters

m (global) INTEGER. The number of rows of matrix *A* to be copied (*m*≥0).

n (global) INTEGER. The number of columns of matrix *A* to be copied (*n*≥0).

a (local)

REAL for psgemr2d

DOUBLE for pdgemr2d

COMPLEX for pcgemr2d

DOUBLE COMPLEX for pzgemr2d

INTEGER for pigemr2d.

Pointer into the local memory to array of size *lld_a* by *LOCc*(*ja*+*n*-1) containing the source matrix *A*.

ia, *ja* (global) INTEGER. The row and column indices in the array *A* indicating the first row and the first column, respectively, of the submatrix of *A*) to copy. 1 ≤*ia*≤*total_rows_in_a* - *m* +1, 1 ≤*ja*≤*total_columns_in_a* - *n* +1.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

Only *dtype_a* = 1 is supported, so *dlen_* = 9.

If the calling process is not part of the context of *A*, *ctxt_a* must be equal to -1.

ib, *jb* (global) INTEGER. The row and column indices in the array *B* indicating the first row and the first column, respectively, of the submatrix *B* to which to copy the matrix. 1 ≤*ib*≤*total_rows_in_b* - *m* +1, 1 ≤*jb*≤*total_columns_in_b* - *n* +1.

descb (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

Only *dtype_b* = 1 is supported, so *dlen_* = 9.

If the calling process is not part of the context of *B*, *ctxt_b* must be equal to -1.

ictxt (global)INTEGER.

The context encompassing at least the union of all processes in context *A* and context *B*. All processes in the context *ictxt* must call this routine, even if they do not own a piece of either matrix.

Output Parameters

b

REAL for psgemr2d

DOUBLE for pdgemr2d

COMPLEX for pcgemr2d

DOUBLE COMPLEX for pzgemr2d

INTEGER for pigemr2d.

Pointer into the local memory to array of size *lld_b* by *LOCc(jb+n-1)*.

Overwritten by the submatrix from *A*.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?trmr2d

Copies a submatrix from one trapezoidal matrix to another.

Syntax

```
call pstrmr2d(uplo, diag, m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pdtrmr2d(uplo, diag, m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pctrmr2d(uplo, diag, m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pztrmr2d(uplo, diag, m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
call pitrmr2d(uplo, diag, m, n, a, ia, ja, desca, b, ib, jb, descb, ictxt)
```

Description

The p?trmr2d routine copies the indicated matrix or submatrix of *A* to the indicated matrix or submatrix of *B*. It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With p?gemr2d, these routines are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix *A* in context *A* (distributed over process grid *A*) and copy it to a matrix or submatrix *B* in context *B* (distributed over process grid *B*).

The p?trmr2d routine assumes the matrix or submatrix to be trapezoidal. Only the upper or lower part is copied, and the other part is unchanged.

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context *A* is disjoint from context *B*. The general rules for which parameters need to be set are:

- All calling processes must have the correct *m* and *n*.
- Processes in context *A* must correctly define all parameters describing *A*.
- Processes in context *B* must correctly define all parameters describing *B*.
- Processes which are not members of context *A* must pass *ctxt_a* = -1 and need not set other parameters describing *A*.
- Processes which are not members of context *B* must pass *ctxt_b* = -1 and need not set other parameters describing *B*.

Because of its generality, p?trmr2d can be used for many operations not usually associated with copy routines. For instance, it can be used to a take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for instance, this routine can be used to move the matrix from the workstation to the supercomputer and back. In ScaLAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this routine requires an array descriptor with *dtype_* = 1.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Input Parameters

uplo (global) CHARACTER*1. Specifies whether to copy the upper or lower part of the matrix or submatrix.

uplo = 'U'	Copy the upper triangular part.
uplo = 'L'	Copy the lower triangular part.

diag (global) CHARACTER*1. Specifies whether to copy the diagonal of the matrix or submatrix.

diag = 'U'	Do not copy the diagonal.
diag = 'N'	Copy the diagonal.

m (global) INTEGER. The number of rows of matrix *A* to be copied ($m \geq 0$).

n (global) INTEGER. The number of columns of matrix *A* to be copied ($n \geq 0$).

a (local)

REAL for pstrmr2d

DOUBLE for pdtrmr2d

COMPLEX for pctrmr2d

DOUBLE COMPLEX for pztrmr2d

INTEGER for pitrmr2d.

Pointer into the local memory to array of size *lld_a* by *LOCc(ja+n-1)* containing the source matrix *A*.

ia, *ja* (global) INTEGER. The row and column indices in the array *A* indicating the first row and the first column, respectively, of the submatrix of *A*) to copy. $1 \leq ia \leq total\_rows\_in\_a - m + 1$, $1 \leq ja \leq total\_columns\_in\_a - n + 1$.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

Only *dtype_a* = 1 is supported, so *dlen_* = 9.

If the calling process is not part of the context of *A*, *ctxt_a* must be equal to -1.

ib, *jb* (global) INTEGER. The row and column indices in the array *B* indicating the first row and the first column, respectively, of the submatrix *B* to which to copy the matrix. $1 \leq ib \leq total\_rows\_in\_b - m + 1$, $1 \leq jb \leq total\_columns\_in\_b - n + 1$.

descb (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

Only *dtype_b* = 1 is supported, so *dlen_* = 9.

If the calling process is not part of the context of *B*, *ctxt_b* must be equal to -1.

ictxt (global)INTEGER.

The context encompassing at least the union of all processes in context *A* and context *B*. All processes in the context *ictxt* must call this routine, even if they do not own a piece of either matrix.

Output Parameters

b REAL for pstrmr2d

DOUBLE for pdtrmr2d

COMPLEX for pctrmr2d

DOUBLE COMPLEX for pztrmr2d

INTEGER for pitrmr2d.

Pointer into the local memory to array of size *lld_b* by *LOCc(jb+n-1)*.

Overwritten by the submatrix from *A*.

Sparse Solver Routines

Intel® oneAPI Math Kernel Library (oneMKL) sparse solver algorithms for solving real or complex, symmetric, structurally symmetric or nonsymmetric, positive definite, indefinite or Hermitian square sparse linear system of algebraic equations.

The terms and concepts required to understand the use of the Intel® oneAPI Math Kernel Library (oneMKL) sparse solver routines are discussed in the Appendix "Linear Solvers Basics". If you are familiar with linear sparse solvers and sparse matrix storage schemes, you can skip these sections and go directly to the interface descriptions.

See the description of

- the direct sparse solver based on PARDISO*, which is referred to here as Intel MKL PARDISO;
- the alternative interface for the direct sparse solver, which is referred to here as the DSS interface;
- iterative sparse solvers (ISS) based on the reverse communication interface (RCI);
- preconditioners based on the incomplete LU factorization technique.
- a direct sparse solver based on QR decomposition.

oneMKL PARDISO - Parallel Direct Sparse Solver Interface

This section describes the interface to the shared-memory multiprocessing parallel direct sparse solver known as the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver.

The Intel® oneAPI Math Kernel Library (oneMKL) PARDISO package is a high-performance, robust, memory efficient, and easy to use software package for solving large sparse linear systems of equations on shared memory multiprocessors. The solver uses a combination of left- and right-looking Level-3 BLAS supernode techniques [Schenk00-2]. To improve sequential and parallel sparse numerical factorization performance, the algorithms are based on a Level-3 BLAS update and pipelining parallelism is used with a combination of left- and right-looking supernode techniques [Schenk00, Schenk01, Schenk02, Schenk03]. The parallel pivoting

methods allow complete supernode pivoting to compromise numerical stability and scalability during the factorization process. For sufficiently large problem sizes, numerical experiments demonstrate that the scalability of the parallel algorithm is nearly independent of the shared-memory multiprocessing architecture.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

The following table lists the names of the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO routines and describes their general use.

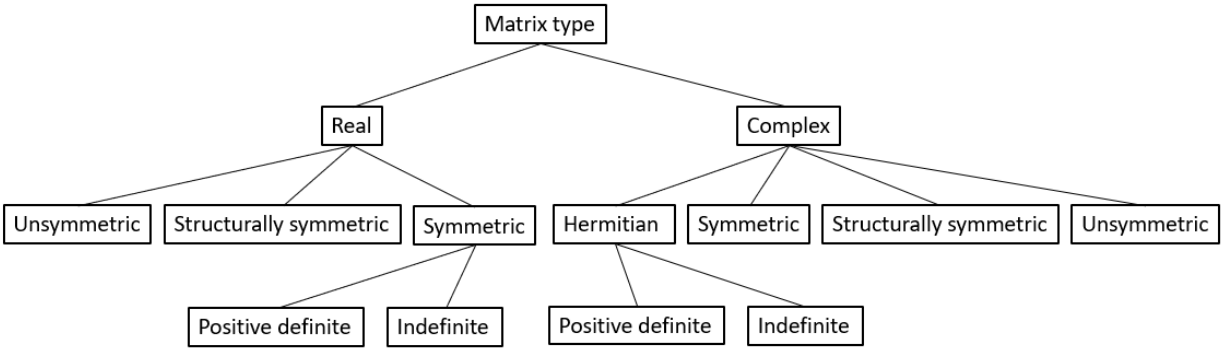
oneMKL PARDISO Routines

Routine	Description
pardisoinit	Initializes Intel® oneAPI Math Kernel Library (oneMKL) PARDISO with default parameters depending on the matrix type.
pardiso	Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.
pardiso_64	Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides, 64-bit integer version.
mkl_pardiso_pivot	Replaces routine which handles Intel® oneAPI Math Kernel Library (oneMKL) PARDISO pivots with user-defined routine.
pardiso_getdiag	Returns diagonal elements of initial and factorized matrix.
pardiso_export	Places pointers dedicated for sparse representation of requested matrix into MKL PARDISO.
pardiso_handle_store	Store internal structures from `pardiso` to a file.
pardiso_handle_restore	Restore `pardiso` internal structures from a file.
pardiso_handle_delete	Delete files with `pardiso` internal structure data.
pardiso_handle_store_64	Store internal structures from `pardiso_64` to a file.
pardiso_handle_restore_64	Restore `pardiso_64` internal structures from a file.
pardiso_handle_delete_64	Delete files with `pardiso_64` internal structure data.

The Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver supports a wide range of real and complex sparse matrix types (seethe figure below).

__border__top

Sparse Matrices That Can Be Solved with the oneMKL PARDISO Solver



The Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver performs four tasks:

- analysis and symbolic factorization
- numerical factorization
- forward and backward substitution including iterative refinement
- termination to release all internal solver memory.

To find code examples that use Intel® oneAPI Math Kernel Library (oneMKL) PARDISO routines to solve systems of linear equations, unzip theappropriate Fortran archive file in the `examples`folder of the Intel® oneAPI Math Kernel Library (oneMKL) installation directory. Code examples will be in the`examples/solverf/source` folder.

Supported Matrix Types

The analysis steps performed by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO depend on the structure of the input matrix*A*.

Symmetric Matrices

The solver first computes a symmetric fill-in reducing permutation *P* based on either the minimum degree algorithm [Liu85] or the nested dissection algorithm from the METIS package [Karypis98] (both included with Intel® oneAPI Math Kernel Library (oneMKL)), followed by the parallel left-right looking numerical Cholesky factorization [Schenk00-2] of $PAP^T = LL^T$ for symmetric positive-definite matrices, or $PAP^T = LDL^T$ for symmetric indefinite matrices. The solver uses diagonal pivoting, or 1x1 and 2x2 Bunch-Kaufman pivoting for symmetric indefinite matrices. An approximation of *X* is found by forward and backward substitution and optional iterative refinement.

Whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal supernode block, the coefficient matrix is perturbed. One or two passes of iterative refinement may be required to correct the effect of the perturbations. This restricting notion of pivoting with iterative refinement is effective for highly indefinite symmetric systems. Furthermore, for a large set of matrices from different applications areas, this method is as accurate as a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Another method of improving the pivoting accuracy is to use symmetric weighted matching algorithms. These algorithms identify large entries in the coefficient matrix A that, if permuted close to the diagonal, permit the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. These algorithms are based on maximum weighted matchings and improve the quality of the factor in a complementary way to the alternative of using more complete pivoting techniques.

The inertia is also computed for real symmetric indefinite matrices.

Structurally Symmetric Matrices

The solver first computes a symmetric fill-in reducing permutation P followed by the parallel numerical factorization of $PAP^T = QLU^T$. The solver uses partial pivoting in the supernodes and an approximation of X is found by forward and backward substitution and optional iterative refinement.

Nonsymmetric Matrices

The solver first computes a nonsymmetric permutation P_{MPS} and scaling matrices D_r and D_c with the aim of placing large entries on the diagonal to enhance reliability of the numerical factorization process [Duff99]. In the next step the solver computes a fill-in reducing permutation P based on the matrix $P_{MPS}A + (P_{MPS}A)^T$ followed by the parallel numerical factorization

$QLUR = PP_{MPS}D_rAD_cP$

with supernode pivoting matrices Q and R. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99]. The magnitude of the potential pivot is tested against a constant threshold of

$\texttt{alpha} = \texttt{eps} * ||A2||_{\texttt{inf}}$,

where `eps` is the machine precision, $A2 = P*P_{MPS}*D_r*A*D_c*P$, and $||A2||_{\texttt{inf}}$ is the infinity norm of A. Any tiny pivots encountered during elimination are set to the sign $(l_{II})*\texttt{eps}*||A2||_{\texttt{inf}}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Although many failures could render the factorization well-defined but essentially useless, in practice the diagonal elements are rarely modified for a large class of matrices. The result of this pivoting approach is that the factorization is, in general, not exact and iterative refinement may be needed.

Sparse Data Storage

Intel® oneAPI Math Kernel Library (oneMKL) PARDISO stores sparse data in several formats:

- CSR3: The 3-array variation of the compressed sparse row format described in Three Array Variation of CSR Format.
- BSR3: The three-array variation of the block compressed sparse row format described in Three Array Variation of BSR Format. Use `iparm(37)` to specify the block size.
- VBSR: Variable BSR format. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO analyzes the matrix provided in CSR3 format and converts it into an internal structure which can improve performance for matrices with a block structure. Use `iparm(37) = -t` ($0 < t \leq 100$) to specify use of internal VBSR format and to set the degree of similarity required to combine elements of the matrix. For example, if you set `iparm(37) = -80`, two rows of the input matrix are combined when their non-zero patterns are 80% or more similar.

NOTE
Intel® oneAPI Math Kernel Library (oneMKL) supports only the VBSR format for real and symmetric positive definite or indefinite matrices (*mtype* = 2 or *mtype* = -2).

Intel® oneAPI Math Kernel Library (oneMKL) supports these features for all matrix types as long as*iparm*(24)=1:

- *iparm*(31) > 0: Partial solution
- *iparm*(36) > 0: Schur complement
- *iparm*(60) > 0: OOC Intel® oneAPI Math Kernel Library (oneMKL) PARDISO

For all storage formats, the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO parameter*ja* is used for the *columns* array, *ia* is used for *rowIndex*, and *a* is used for *values*. The algorithms in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO require column indices*ja* to be in increasing order per row and that the diagonal element in each row be present for any structurally symmetric matrix. For symmetric or nonsymmetric matrices the diagonal elements which are equal to zero are not necessary.

Caution
Intel® oneAPI Math Kernel Library (oneMKL) PARDISO column indices*ja* must be in increasing order per row. You can validate the sparse matrix structure with the matrix checker (*iparm*(27))

NOTE
While the presence of zero diagonal elements for symmetric matrices is not required, you should explicitly set zero diagonal elements for symmetric matrices. Otherwise, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO creates internal copies of arrays*ia*, *ja*, and *a* full of diagonal elements, which require additional memory and computational time. However, the memory and time required the diagonal elements in internal arrays is usually not significant compared to the memory and the time required to factor and solve the matrix.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Storage of Matrices

By default, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO stores data in RAM. This is referred to as In-Core (IC) mode. However, you can specify that Intel® oneAPI Math Kernel Library (oneMKL) PARDISO store matrices on disk by setting*iparm*(60). This mode is called the Out-of-Core (OOC) mode.

You can set the following parameters for the OOC mode.

Parameter/Environment Variable Name	Description
MKL_PARDISO_OOC_PATH	Directory for storing data created in the OOC mode.
MKL_PARDISO_OOC_FILE_NAME	Full file name (incl. path) which will be used for the OOC files

Parameter/Environment Variable Name	Description
MKL_PARDISO_OOC_MAX_CORE_SIZE	Maximum size of RAM (in megabytes) available for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO
MKL_PARDISO_OOC_MAX_SWAP_SIZE	Maximum swap size (in megabytes) available for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO
MKL_PARDISO_OOC_KEEP_FILE	A flag which determines whether temporary data files will be deleted or stored

By default, the current working directory is used in the OOC mode as a directory path for storing data. All work arrays will be stored in files named ooc_temp with different extensions. When MKL_PARDISO_OOC_FILE_NAME is not set and MKL_PARDISO_OOC_PATH is set, the names for the created files will contain <path>/mkl_pardiso or <path>\mkl_pardiso depending on the OS. Setting MKL_PARDISO_OOC_FILE_NAME=<filename> will override the path which could have been set in MKL_PARDISO_OOC_PATH. In this case <filename> will be used for naming the OOC files.

By default, MKL_PARDISO_OOC_MAX_CORE_SIZE is 2000 (MB) and MKL_PARDISO_OOC_MAX_SWAP_SIZE is 0.

NOTE
Do not set the sum of MKL_PARDISO_OOC_MAX_CORE_SIZE and MKL_PARDISO_OOC_MAX_SWAP_SIZE greater than the size of the RAM plus the size of the swap memory. Be sure to allow enough free memory for the operating system and any other processes which need to be running.

By default, all temporary data files will be deleted. For keeping them it is required to set MKL_PARDISO_OOC_KEEP_FILE to 0.

OOC parameters can be set in a configuration file. You can set the path to this file and its name using environmental variables MKL_PARDISO_OOC_CFG_PATH and MKL_PARDISO_OOC_CFG_FILE_NAME.

For setting parameters of OOC mode either environment variables or a configuration file can be used. When the last option is chosen, by default the name of the file is *pardiso_ooc.cfg* and it should be placed in the working directory. If needed, the user can set the path to the configuration file using environmental variables MKL_PARDISO_OOC_CFG_PATH and MKL_PARDISO_OOC_CFG_FILE_NAME. These variables specify the path and filename as follows:

- Linux* OS and OS X*: <MKL_PARDISO_OOC_CFG_PATH>/ <MKL_PARDISO_OOC_CFG_FILE_NAME>
- Windows* OS: <MKL_PARDISO_OOC_CFG_PATH>\<MKL_PARDISO_OOC_CFG_FILE_NAME>

An example of the configuration file:

```
MKL_PARDISO_OOC_PATH = <path>
MKL_PARDISO_OOC_MAX_CORE_SIZE = N
MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

Caution
The maximum length of the path lines in the configuration files is 1000 characters.

Alternatively, the OOC parameters can be set as environment variables via command line.

For Linux* OS and OS X*:

```
export MKL_PARDISO_OOC_PATH = <path>
export MKL_PARDISO_OOC_MAX_CORE_SIZE = N
export MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
export MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

For Windows* OS:

```
set MKL_PARDISO_OOC_PATH = <path>
set MKL_PARDISO_OOC_MAX_CORE_SIZE = N
set MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
set MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

where `<path>` should follow the OS naming convention.

Direct-Iterative Preconditioning for Nonsymmetric Linear Systems

The solver uses a combination of direct and iterative methods [Sonn89] to accelerate the linear solution process for transient simulation. Most applications of sparse solvers require solutions of systems with gradually changing values of the nonzero coefficient matrix, but with an identical sparsity pattern. In these applications, the analysis phase of the solvers has to be performed only once and the numerical factorizations are the important time-consuming steps during the simulation. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses a numerical factorization and applies the factors in a preconditioned Krylov Subspace iteration. If the iteration does not converge, the solver automatically switches back to the numerical factorization. This method can be applied to nonsymmetric matrices in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. You can select the method using the *iparm*(4) input parameter. The *iparm*(20) parameter returns the error status after running Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

Single and Double Precision Computations

Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solves tasks using single or double precision. Each precision has its benefits and drawbacks. Double precision variables have more digits to store value, so the solver uses more memory for keeping data. But this mode solves matrices with better accuracy, which is especially important for input matrices with large condition numbers.

Single precision variables have fewer digits to store values, so the solver uses less memory than in the double precision mode. Additionally this mode usually takes less time. But as computations are made less precisely, only some systems of equations can be solved accurately enough using single precision.

Separate Forward and Backward Substitution

The solver execution step (see parameter *phase* = 33 below) can be divided into two or three separate substitutions: forward, backward, and possible diagonal. This separation can be explained by the examples of solving systems with different matrix types.

A real symmetric positive definite matrix *A* (*mtype* = 2) is factored by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO as $A = L*L^T$. In this case the solution of the system $A*x=b$ can be found as sequence of substitutions: $L*y=b$ (forward substitution, *phase* =331) and $L^T*x=y$ (backward substitution, *phase* =333).

A real nonsymmetric matrix *A* (*mtype* = 11) is factored by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO as $A = L*U$. In this case the solution of the system $A*x=b$ can be found by the following sequence: $L*y=b$ (forward substitution, *phase* =331) and $U*x=y$ (backward substitution, *phase* =333).

Solving a system with a real symmetric indefinite matrix *A* (*mtype* = -2) is slightly different from the cases above. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO factors this matrix as $A=LDL^T$, and the solution of the system $A*x=b$ can be calculated as the following sequence of substitutions: $L*y=b$ (forward

substitution, *phase* =331), $D*y=y$ (diagonal substitution, *phase* =332), and finally $L^T*x=y$ (backward substitution, *phase* =333). Diagonal substitution makes sense only for symmetric indefinite matrices (*mtype* = -2, -4, 6). For matrices of other types a solution can be found as described in the first two examples.

Caution
The number of refinement steps (*iparm(8)*) must be set to zero if a solution is calculated with separate substitutions (*phase* = 331, 332, 333), otherwise Intel® oneAPI Math Kernel Library (oneMKL) PARDISO produces the wrong result.

NOTE
Different pivoting (*iparm(21)*) produces different LDL^T factorization. Therefore results of forward, diagonal and backward substitutions with diagonal pivoting can differ from results of the same steps with Bunch-Kaufman pivoting. Of course, the final results of sequential execution of forward, diagonal and backward substitution are equal to the results of the full solving step (*phase*=33) regardless of the pivoting used.

Callback Function for Pivoting Control

In-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO allows you to control pivoting with a callback routine,mkl_pardiso_pivot. You can then use the pardiso_getdiag routine to access the diagonal elements. Set iparm(56) to 1 in order to use the callback functionality.

Low Rank Update

Use low rank update to accelerate the factorization step in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO when you use multiple matrices with identical structure and similar values. After callingpardiso in the usual manner for factorization (*phase* = 12, 13, 22, or 23) for some matrix *A1*, low rank update can be applied to the factorization step (*phase* = 22 or 23) of some matrix *A2* with identical structure.

To use the low rank update feature, set *iparm*(39) = 1 while also setting *iparm*(24) = 10. Additionally, supply an array that lists the values in *A2* that are different from *A1* using the *perm* parameter as outlined in the pardiso *perm* parameter description.

Important
Low rank update can only be called for matrices with the exact same pattern of nonzero values. As such, the value of the *mtype*, *ia*, *ja*, and *iparm*(24) parameters should also be identical. In general, the low rank factorization should be called with the same parameters as the preceding factorization step for the same internal data structure handle (except for array *a*, *iparm*(39), and *perm*).

Low rank update does not currently support Intel TBB threading. In this case, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO defaults to full factorization instead.

Low rank update cannot be used in combination with a user-supplied permutation vector - in other words, you must use the default values of *iparm*(5) = 0, *iparm*(31) = 0, and *iparm*(36) = 0). Additionally, *iparm*(4), *iparm*(6), *iparm*(12), *iparm*(28), *iparm*(37), *iparm*(56), and *iparm*(60) must all be set to the default value of 0.

pardiso

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.

Syntax

`call pardiso (pt, maxfct, mnum, mtype, phase, n, a, ia, ja, perm, nrhs, iparm, msglvl, b, x, error)`

Include Files

- `mkl.fi, mkl_pardiso.f90`

Description

The `pardiso` routine calculates the solution of a set of sparse linear equations

```
A*X = B
```

with single or multiple right-hand sides, using a parallel *LU*, *LDL*, or LL^T factorization, where *A* is an *n*-by-*n* matrix, and *X* and *B* are *n*-by-*nrhs* vectors or matrices.

Notes

- This routine supports usage of the `mkl_progress` with OpenMP, TBB, and sequential threading. See `mkl_progress` for details. The case of *iparm*(24)=10 does not support this feature.
- If *iparm*(27) is set to 1 (Matrix checker), Intel® oneAPI Math Kernel Library PARDISO uses the auxiliary routine `sparse_matrix_checker` to check integer arrays `ia` and `ja`. `sparse_matrix_checker` has its own set of error values (from 21 to 24) that are returned in the event of an unsuccessful matrix check. For more details, refer to the sparse_matrix_checker documentation.

Input Parameters

NOTE
The types given for parameters in this section are specified in FORTRAN 77 notation. See Intel MKL PARDISO Parameters in Tabular Formfor detailed description of types of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO parameters in Fortran 90 notation.

pt

`INTEGER` for 32-bit or 64-bit architectures

`INTEGER*8` for 64-bit architectures

Array with size of 64.

Handle to internal data structure. The entries must be set to zero prior to the first call to `pardiso`. Unique for factorization.

Caution
After the first call to `pardiso` do not directly modify *pt*, as that could cause a serious memory leak.

Use the pardiso_handle_store or `pardiso_handle_store_64` routine to store the content of *pt* to a file. Restore the contents of *pt* from the file using pardiso_handle_restore or `pardiso_handle_restore_64`. Use `pardiso_handle_store` and `pardiso_handle_restore` with `pardiso`, and `pardiso_handle_store_64` and `pardiso_handle_restore_64` with `pardiso_64`.

maxfct INTEGER

Maximum number of factors with identical sparsity structure that must be kept in memory at the same time. In most applications this value is equal to 1. It is possible to store several different factorizations with the same nonzero structure at the same time in the internal data structure management of the solver.

`pardiso` can process several matrices with an identical matrix sparsity pattern and it can store the factors of these matrices at the same time. Matrices with a different sparsity structure can be kept in memory with different memory address pointers *pt*.

mnum INTEGER

Indicates the actual matrix for the solution phase. With this scalar you can define which matrix to factorize. The value must be: $1 \leq mnum \leq maxfct$.

In most applications this value is 1.

mtype INTEGER

Defines the matrix type, which influences the pivoting method. The Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver supports the following matrices:

1	real and structurally symmetric
2	real and symmetric positive definite
-2	real and symmetric indefinite
3	complex and structurally symmetric
4	complex and Hermitian positive definite
-4	complex and Hermitian indefinite
6	complex and symmetric
11	real and nonsymmetric
13	complex and nonsymmetric

phase INTEGER

Controls the execution of the solver. Usually it is a two- or three-digit integer. The first digit indicates the starting phase of execution and the second digit indicates the ending phase. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including optional iterative refinement

  This phase can be divided into two or three separate substitutions: forward, backward, and diagonal (see Separate Forward and Backward Substitution).
- Memory release phase (*phase*= 0 or *phase*= -1)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

phase	**Solver Execution Steps**
11	Analysis
12	Analysis, numerical factorization
13	Analysis, numerical factorization, solve, iterative refinement
22	Numerical factorization
23	Numerical factorization, solve, iterative refinement
33	Solve, iterative refinement
331	like *phase*=33, but only forward substitution
332	like *phase*=33, but only diagonal substitution (if available)
333	like *phase*=33, but only backward substitution
0	Release internal memory for *L* and *U* matrix number *mnum*
-1	Release all internal memory for all matrices

If *iparm*(36) = 0, phases 331, 332, and 333 perform this decomposition:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{12} & L_{22} \end{bmatrix} \begin{bmatrix} D_{11} & 0 \\ 0 & D_{22} \end{bmatrix} \begin{bmatrix} U_{11} & U_{21} \\ 0 & U_{22} \end{bmatrix}$$

If *iparm*(36) = 2, phases 331, 332, and 333 perform a different decomposition:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{12} & I \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & S \end{bmatrix} \begin{bmatrix} U_{11} & U_{21} \\ 0 & I \end{bmatrix}$$

You can supply a custom implementation for phase 332 instead of calling pardiso. For example, it can be implemented with dense LAPACK functionality. Custom implementation also allows you to substitute the matrix *S* with your own.

NOTE
For very large Schur complement matrices use LAPACK functionality to compute the Schur complement vector instead of the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO phase 332 implementation.

n

INTEGER

Number of equations in the sparse linear systems of equations *A*X = B*. Constraint: *n* > 0.

a

DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*(28) =0)

REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*(28) =1)

DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*(28) =0)

COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*(28) =1)

Array. Contains the non-zero elements of the coefficient matrix *A* corresponding to the indices in *ja*. The coefficient matrix can be either real or complex. The matrix must be stored in the three-array variant of the compressed sparse row (CSR3) or in the three-array variant of the block compressed sparse row (BSR3) format, and the matrix must be stored with increasing values of *ja* for each row.

For CSR3 format, the size of *a* is the same as that of *ja*. Refer to the *values* array description in Three Array Variation of CSR Format for more details.

For BSR3 format the size of *a* is the size of *ja* multiplied by the square of the block size. Refer to the *values* array description in Three Array Variation of BSR Format for more details.

NOTE
If you set *iparm*(37) to a negative value, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO converts the data from CSR3 format to an internal variable BSR (VBSR) format. SeeSparse Data Storage.

ia

INTEGER

Array, size (*n*+1).

For CSR3 format, *ia*(*i*) (*i*≤*n*) points to the first column index of row *i* in the array *ja*. That is, *ia*(*i*) gives the index of the element in array *a* that contains the first non-zero element from row *i* of *A*. The last element *ia*(*n*+1) is taken to be equal to the number of non-zero elements in *A*, plus one. Refer to *rowIndex* array description in Three Array Variation of CSR Format for more details.

For BSR3 format, *ia*(*i*) (*i*≤*n*) points to the first column index of row *i* in the array *ja*. That is, *ia*(*i*) gives the index of the element in array *a* that contains the first non-zero block from row *i* of *A*. The last element *ia*(*n*+1) is taken to be equal to the number of non-zero blcoks in *A*, plus one. Refer to *rowIndex* array description in Three Array Variation of BSR Format for more details.

The array *ia* is accessed in all phases of the solution process.

Indexing of *ia* is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter *iparm*(35).

ja

INTEGER

For CSR3 format, array *ja* contains column indices of the sparse matrix *A*. It is important that the indices are in increasing order per row. For structurally symmetric matrices it is assumed that all diagonal elements are stored (even if they are zeros) in the list of non-zero elements in *a* and *ja*. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in Three Array Variation of CSR Format.

For BSR3 format, array *ja* contains column indices of the sparse matrix *A*. It is important that the indices are in increasing order per row. For structurally symmetric matrices it is assumed that all diagonal blocks are stored (even if they are zeros) in the list of non-zero blocks in *a* and *ja*. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in Three Array Variation of BSR Format.

The array *ja* is accessed in all phases of the solution process.

Indexing of *ja* is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter *iparm*(35).

perm

INTEGER

Array, size (*n*). Depending on the value of *iparm*(5) and *iparm*(31), holds the permutation vector of size *n*, specifies elements used for computing a partial solution, or specifies differing values of the input matrices for low rank update.

- If *iparm*(5) = 1, *iparm*(31) = 0, and *iparm*(36) = 0, *perm* specifies the fill-in reducing ordering to the solver. Let *A* be the original matrix and $C = P*A*P^T$ be the permuted matrix. Row (column) *i* of *C* is the *perm*(*i*) row (column) of *A*. The array *perm* is also used to return the permutation vector calculated during fill-in reducing ordering stage.

NOTE
Be aware that setting *iparm*(5) = 1 prevents use of a parallel algorithm for the solve step.

- If *iparm*(5) = 2, *iparm*(31) = 0, and *iparm*(36) = 0, the permutation vector computed in phase 11 is returned in the *perm* array.
- If *iparm*(5) = 0, *iparm*(31) > 0, and *iparm*(36) = 0, *perm* specifies elements of the right-hand side to use or of the solution to compute for a partial solution.
- If *iparm*(5) = 0, *iparm*(31) = 0, and *iparm*(36) > 0, *perm* specifies elements for a Schur complement.
- If *iparm*(39) = 1, *perm* specifies values that differ in *A* for low rank update (see Low Rank Update). The size of the array must be at least 2**ndiff* + 1, where *ndiff* is the number of values of *A* that are different. The values of *perm* should be:

  perm = {*ndiff*, *row_index1*, *column_index1*, *row_index2*, *column_index2*, ..., *row_index_ndiff*, *column_index_ndiff*}

  where *row_index_m* and *column_index_m* are the row and column indices of the *m*-th differing non-zero value in matrix *A*. The row and column index pairs can be in any order, but must use zero-based indexing regardless of the value of *iparm*(35).

See *iparm*(5), *iparm*(31), and *iparm*(39) for more details.

Indexing of *perm* is one-based by default, but unless *iparm*(39) = 1 it can be changed to zero-based by setting the appropriate value to the parameter *iparm*(35).

nrhs

INTEGER

Number of right-hand sides that need to be solved for.

iparm

INTEGER

Array, size (64). This array is used to pass various parameters to Intel® oneAPI Math Kernel Library (oneMKL) PARDISO and to return some useful information after execution of the solver.

See pardiso iparm Parameter for more details about the *iparm* parameters.

msglvl

INTEGER

Message level information. If *msglvl* = 0 then pardiso generates no output, if *msglvl* = 1 the solver prints statistical information to the screen.

b

DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*(28)=0)

REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*(28)=1)

DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*(28)=0)

COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm(28)*=1)

Array, size (*n*, *nrhs*). On entry, contains the right-hand side vector/matrix *B*, which is placed in memory contiguously. The *b*(i+(k-1)×*nrhs*) element must hold the i-th component of k-th right-hand side vector. Note that *b* is only accessed in the solution phase.

Output Parameters

(See also Intel MKL PARDISO Parameters in Tabular Form.)

pt — Handle to internal data structure.

perm — See the Input Parameter description of the *perm* array.

iparm — On output, some *iparm* values report information such as the numbers of non-zero elements in the factors.

See pardiso iparm Parameter for more details about the *iparm* parameters.

b — On output, the array is replaced with the solution if *iparm(6)* = 1.

x

DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm(28)*=0)

REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm(28)*=1)

DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm(28)*=0)

COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm(28)*=1)

Array, size (*n*, *nrhs*). If *iparm(6)*=0 it contains solution vector/matrix *X*, which is placed contiguously in memory. The *x*(i+(k-1)× *n*) element must hold the i-th component of the k-th solution vector. Note that *x* is only accessed in the solution phase.

error — INTEGER

The error indicator according to the below table:

error	**Information**
0	no error
-1	input inconsistent
-2	not enough memory
-3	reordering problem

error	Information
-4	Zero pivot, numerical factorization or iterative refinement problem. If the error appears during the solution phase, try to change the pivoting perturbation (*iparm*(10)) and also increase the number of iterative refinement steps. If it does not help, consider changing the scaling, matching and pivoting options (*iparm*(11), *iparm*(13), *iparm*(21))
-5	unclassified (internal) error
-6	reordering failed (matrix types 11 and 13 only)
-7	diagonal matrix is singular
-8	32-bit integer overflow problem
-9	not enough memory for OOC
-10	error opening OOC files
-11	read/write error with OOC files
-12	(pardiso_64 only) pardiso_64 called from 32-bit library
-13	interrupted by the (user-defined) mkl_progress function
-15	internal error which can appear for *iparm*(24)=10 and *iparm*(13)=1. Try switch matching off (set *iparm*(13)=0 and rerun.)

pardisoinit

Initialize Intel® oneAPI Math Kernel Library (oneMKL) PARDISO with default parameters in accordance with the matrix type.

Syntax

```
call pardisoinit (pt, mtype, iparm)
```

Include Files

- mkl.fi, mkl_pardiso.f90

Description

This function initializes the solver handle *pt* for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO with zero values (as needed for the very first call of pardiso) and sets default *iparm* values in accordance with the matrix type *mtype*.

The recommended way is to avoid using pardisoinit and to initialize *pt* and set the values of the *iparm* array manually as the default parameters might not be the best for a particular use case.

An alternative method to set default *iparm* values is to call pardiso in the analysis phase with iparm(1)=0. In this case, the solver handle *pt* must be initialized with zero values.

The pardisoinit routine initializes only the in-core version of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. Switching to the out-of-core version of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO as well as changing default *iparm* values can be done after the call to pardisoinit but before the first call to pardiso.

The pardisoinit routine cannot be used together with the pardiso_64 routine.

Input Parameters

mtype

INTEGER

Matrix type. Based on this value pardisoinit chooses default values for the *iparm* array. Refer to the section oneMKL PARDISO Parameters in Tabular Formfor more details about the default values of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

Output Parameters

pt

INTEGER for 32-bit or 64-bit architectures

INTEGER*8 for 64-bit architectures

Array of size 64. Handle to internal data structure. The pardisoinit routine nullifies the array *pt*.

NOTE
It is very important that *pt* is initialized with zero before the first call of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. After that first call you must never modify the array, because it could cause a serious memory leak or a crash.

iparm

INTEGER

Array of size 64. This array is used to set various options for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO and to return some useful information after execution of the solver. Thepardisoinit routine fills in the *iparm* array with the default values. Refer to the section oneMKL PARDISO Parameters in Tabular Form for more details about the default values of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

pardiso_64

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides, 64-bit integer version.

Syntax

```
call pardiso_64 (pt, maxfct, mnum, mtype, phase, n, a, ia, ja, perm, nrhs, iparm, msglvl, b, x, error)
```

Include Files

- mkl.fi, mkl_pardiso.f90

Description

pardiso_64 is an alternative ILP64 (64-bit integer) version of the pardiso routine (see Description section for more details). The interface of pardiso_64 is the same as the interface of pardiso, but it accepts and returns all INTEGER data as INTEGER*8.

Use pardiso_64 when pardisofor solving large matrices (with the number of non-zero elements on the order of 500 million or more). You can use it together with the usual LP64 interfaces for the rest of Intel® oneAPI Math Kernel Library (oneMKL) functionality. In other words, if you use 64-bit integer version (pardiso_64), you do not need to re-link your applications with ILP64 libraries. Take into account that pardiso_64 may perform slower than regular pardiso on the reordering and symbolic factorization phase.

NOTE
pardiso_64 is supported only in the 64-bit libraries. If pardiso_64 is called from the 32-bit libraries, it returns *error* =-12.

NOTE
This routine supports the Progress Routine feature. See Progress Function for details.

Input Parameters

The input parameters of pardiso_64 are the same as the input parameters of pardiso, but pardiso_64 accepts all INTEGER data as INTEGER*8.

Output Parameters

The output parameters of pardiso_64 are the same as the output parameters of pardiso, but pardiso_64 returns all INTEGER data as INTEGER*8.

mkl_pardiso_pivot

Replaces routine which handles Intel® oneAPI Math Kernel Library (oneMKL) PARDISO pivots with user-defined routine.

Syntax

```
call mkl_pardiso_pivot (ai, bi, eps)
```

Include Files

- mkl.fi, mkl_pardiso.f90

Description

The mkl_pardiso_pivotroutine allows you to handle diagonal elements which arise during numerical factorization that are zero or near zero. By default, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO determines that a diagonal element*bi* is a pivot if *bi* < *eps*, and if so, replaces it with *eps*. But you can provide your own routine to modify the resulting factorized matrix in case there are small elements on the diagonal during the factorization step.

NOTE
To use this routine, you must set *iparm*(56) to 1 before the main pardiso loop.

NOTE
This routine is only available for in-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

Input Parameters

ai — DOUBLE PRECISION - for real types of matrices (*mtype*=2, -2, 4, and 6) and for double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*(28) =0)

Diagonal element of initial matrix corresponding to pivot element.

bi — DOUBLE PRECISION - for real types of matrices (*mtype*=2, -2, 4, and 6) and for double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*(28) =0)

Diagonal element of factorized matrix that could be chosen as a pivot element.

eps — DOUBLE PRECISION

Scalar to compare with diagonal of factorized matrix. On input equal to parameter described by *iparm*(10).

Output Parameters

bi — In case element is chosen as a pivot, value with which to replace the pivot.

pardiso_getdiag

Returns diagonal elements of initial and factorized matrix.

Syntax

```
call pardiso_getdiag (pt, df, da, mnum, error)
```

Include Files

- mkl.fi, mkl_pardiso.f90

Description

This routine returns the diagonal elements of the initial and factorized matrix for a real or Hermitian matrix.

NOTE
In order to use this routine, you must set iparm(56) to 1 before the main pardiso loop.

If iparm(24) is set to 10 (an improved two-level factorization algorithm for nonsymmetric matrices), Intel® oneAPI Math Kernel Library PARDISO will automatically use the classic algorithm for factorization.

Input Parameters

pt — INTEGER for 32-bit or 64-bit architectures

INTEGER*8 for 64-bit architectures

Array with a size of 64. Handle to internal data structure for the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver. The entries must be set to zero prior to the first call to`pardiso`. Unique for factorization.

mnum

`INTEGER`

Indicates the actual matrix for the solution phase of the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver. With this scalar you can define the diagonal elements of the factorized matrix that you want to obtain. The value must be: 1 ≤*mnum* ≤ *maxfct*. In most applications this value is 1.

Output Parameters

df

`DOUBLE PRECISION`- for real types of matrices and for double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*`(28)` =0)

`REAL`- for real types of matrices and for single precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*`(28)` =1)

`DOUBLE COMPLEX`- for complex types of matrices and for double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*`(28)` =0)

`COMPLEX`- for complex types of matrices and for single precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*`(28)` =1)

Array with a dimension of *n*. Contains diagonal elements of the factorized matrix after factorization.

> **NOTE**
> Elements of *df* correspond to diagonal elements of matrix *L*computed during phase 22. Because during phase 22 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO makes additional permutations to improve stability, it is possible that array*df* is not in line with the *perm* array computed during phase 11.

da

`DOUBLE PRECISION`- for real types of matrices and for double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*`(28)` =0)

`REAL`- for real types of matrices and for single precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*`(28)` =1)

`DOUBLE COMPLEX`- for complex types of matrices and for double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*`(28)` =0)

`COMPLEX`- for complex types of matrices and for single precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (*iparm*`(28)` =1)

Array with a dimension of *n*. Contains diagonal elements of the initial matrix.

NOTE
Elements of *da* correspond to diagonal elements of matrix *L*computed during phase 22. Because during phase 22 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO makes additional permutations to improve stability, it is possible that array*da* is not in line with the *perm* array computed during phase 11.

error INTEGER

The error indicator.

error	Information
0	no error
-1	Diagonal information not turned on before pardiso main loop (*iparm*(56)=0).

pardiso_export

Places pointers dedicated for sparse representation of a requested matrix (values, rows, and columns) into MKL PARDISO

Syntax

```
call pardiso_export(pt, values, rows, columns, step, iparm, error)
```

Include Files

- mkl.fi
- mkl_pardiso.f90

Description

This auxiliary routine places pointers dedicated for sparse representation of a requested matrix (values, rows, and columns) into MKL PARDISO. The matrix will be stored in the three-array variant of the compressed sparse row (CSR3 format) with 0-based indexing.

NOTE
Currently, this routine can be used only for a sparse Schur complement matrix. All parameters related to the Schur complement matrix (perm, iparm) must be set before the reordering stage of MKL PARDISO (phase = 11) is called.

Input Parameters

pt(64) INTEGER on 32-bit architectures; INTEGER*8 on 64-bit architectures

Array with a size of 64. Handle to internal data structure for the Intel® MKL PARDISO solver. The entries must be set to zero prior to the first call to pardiso. Unique for factorization.

iparm(64) INTEGER

This array is used to pass various parameters to Intel® MKL PARDISO and to return some useful information after execution of the solver.

step

INTEGER

Stage indicator. These are the currently supported values:

Step value	Notes
1	Used to place pointers related to a Schur complement matrix in MKL PARDISO. The routine with *step* equal to 1 must be called between the reordering and factorization phases of MKL PARDISO.
-1	Used to clean the internal handle.

Input/Output Parameters

values(*)

Parameter type: input/output parameter.

PARDISO_DATA_TYPE (see PARDISO_DATA_TYPE)

This array contains the non-zero elements of the requested matrix.

rows

Parameter type: input/output parameter.

INTEGER

For CSR3 format, `rows[i] ( i < size )` points to the first column index of row i in the array columns; that is, `rows[i]` gives the index of the element in the array values that contains the first non-zero element from row `i` of the sparse matrix. The last element, `rows[size]`, is equal to the number of non-zero elements in the sparse matrix.

columns

Parameter type: input/output parameter.

INTEGER

This array contains the column indices for the non-zero elements of the requested matrix.

error

Parameter type: output parameter.

INTEGER

The error status:

- `0` indicates no error.
- `1` indicates inconsistent input data.

Usage Example

The following C-style example demonstrates how to use the `pardiso_export` routine to get the sparse representation (that is, three-array CSR format) of a Schur complement matrix.

```
#include "mkl.h"

/*
 * Call the reordering phase of MKL PARDISO with iparm[35] set to -1 in
```

```
 * order to compute the Schur complement matrix only, or -2 to compute all
 * factorization arrays.  perm array indices related to the Schur complement
 * matrix must be set to 1.
 */
phase = 11;
for ( i = 0; i < schur_size; i++ ) { perm[i] = 1.; }
iparm[35] = -1;
pardiso(pt, &maxfct, &mnum, &mtype, &phase, &n, a, ia, ja, perm, &nrhs,
  iparm, &msglvl, b, x, &error);

/*
 * After the reordering phase, iparm[35] will contain the number of non-zero
 * elements for the Schur complement matrix.  Arrays dedicated to the sparse
 * representation of the Schur complement matrix must be allocated before
 * the factorization stage of MKL PARDISO is called.
 */
schur_nnz     = iparm[35];
schur_rows    = (MKL_INT   *) mkl_malloc(schur_size+1, ALIGNMENT);
schur_columns = (MKL_INT   *) mkl_malloc(schur_nnz , ALIGNMENT);
schur_values  = (DATA_TYPE *) mkl_malloc(schur_nnz , ALIGNMENT);

/*
 * Call to the pardiso_export routine with step equal to 1 in order to put
 * pointers related to the three-array CSR format into MKL PARDISO:
 */
pardiso_export(pt, schur_values, schur_ia, schur_ja, &step, iparm, &error);

/*
 * Call the factorization phase of PARDISO with iparm[35] equal to -1 or -2
 * to compute the Schur complement matrix:
 */
phase = 22;
iparm[35] = -1;
pardiso(pt, &maxfct, &mnum, &mtype, &phase, &n, a, ia, ja, perm, &nrhs,
  iparm, &msglvl, b, x, &error);

/*
 * After the factorization stage, schur_values, schur_rows, and
 * schur_columns will contain the Schur complement matrix in CSR3 format.
 */
```

pardiso_handle_store

Store internal structures from `pardiso` *to a file.*

Syntax

`call pardiso_handle_store (`*`pt`*`, `*`dirname`*`, `*`error`*`)`

Include Files

- `mkl.fi`, `mkl_pardiso.f90`

Description

This function stores Intel® oneAPI Math Kernel Library (oneMKL) PARDISO structures to a file, allowing you to store Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures between the stages of the`pardiso` routine. The pardiso_handle_restoreroutine can restore the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures from the file.

Input Parameters

pt

`INTEGER` for 32-bit or 64-bit architectures

`INTEGER*8` for 64-bit architectures

Array with a size of 64. Handle to internal data structure.

dirname

`CHARACTER`

String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string ("") to specify the current directory. The routine creates a file named `handle.pds` in the directory.

Output Parameters

pt

Handle to internal data structure.

error

`INTEGER`

The error indicator.

error	Information
`0`	No error.
`-2`	Not enough memory.
`-10`	Cannot open file for writing.
`-11`	Error while writing to file.
`-13`	Wrong file format.

pardiso_handle_restore

Restore `pardiso` *internal structures from a file.*

Syntax

`call pardiso_handle_restore (pt, dirname, error)`

Include Files

- `mkl.fi`, `mkl_pardiso.f90`

Description

This function restores Intel® oneAPI Math Kernel Library (oneMKL) PARDISO structures from a file. This allows you to restore Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures stored by`pardiso_handle_store` after a phase of the `pardiso` routine and continue execution of the next phase.

Input Parameters

dirname

`CHARACTER`

String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Output Parameters

pt

`INTEGER` for 32-bit or 64-bit architectures

`INTEGER*8` for 64-bit architectures

Array with a dimension of 64. Handle to internal data structure.

error

`INTEGER`

The error indicator.

error	Information
`0`	No error.
`-2`	Not enough memory.
`-10`	Cannot open file for reading.
`-11`	Error while reading from file.
`-13`	Wrong file format.

pardiso_handle_delete

Delete files with `pardiso` *internal structure data.*

Syntax

```
call pardiso_handle_delete (dirname, error)
```

Include Files

- `mkl.fi`, `mkl_pardiso.f90`

Description

This function deletes files generated with `pardiso_handle_store`that contain Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures.

Input Parameters

dirname

`CHARACTER`

String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Output Parameters

error

`INTEGER`

The error indicator.

error	Information
`0`	No error.
`-10`	Cannot delete files.

pardiso_handle_store_64

Store internal structures from `pardiso_64` *to a file.*

Syntax

`call pardiso_handle_store_64 (pt, dirname, error)`

Include Files

- `mkl.fi`, `mkl_pardiso.f90`

Description

This function stores Intel® oneAPI Math Kernel Library (oneMKL) PARDISO structures to a file, allowing you to store Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures between the stages of thepardiso_64 routine. The pardiso_handle_restore_64routine can restore the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures from the file.

Input Parameters

pt

`INTEGER*8` for 64-bit architectures

Array with a dimension of 64. Handle to internal data structure.

dirname

`CHARACTER`

String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string ("") to specify the current directory. The routine creates a file named `handle.pds` in the directory.

Output Parameters

pt

Handle to internal data structure.

error

`INTEGER`

The error indicator.

error	Information
`0`	No error.
`-2`	Not enough memory.
`-10`	Cannot open file for writing.
`-11`	Error while writing to file.
`-12`	Not supported in 32-bit library - routine is only supported in 64-bit libraries.
`-13`	Wrong file format.

pardiso_handle_restore_64

Restore `pardiso_64` *internal structures from a file.*

Syntax

`call pardiso_handle_restore_64 (pt, dirname, error)`

Include Files

- mkl.fi, mkl_pardiso.f90

Description

This function restores Intel® oneAPI Math Kernel Library (oneMKL) PARDISO structures from a file. This allows you to restore Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures stored bypardiso_handle_store_64 after a phase of the pardiso_64 routine and continue execution of the next phase.

Input Parameters

dirname CHARACTER

String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Input Parameters

pt INTEGER for 32-bit or 64-bit architectures

INTEGER*8 for 64-bit architectures

Array with a dimension of 64. Handle to internal data structure.

error INTEGER

The error indicator.

error	**Information**
0	No error.
-2	Not enough memory.
-10	Cannot open file for reading.
-11	Error while reading from file.
-13	Wrong file format.

pardiso_handle_delete_64

Syntax

Delete files with pardiso_64 internal structure data.

```
call pardiso_handle_delete_64 (dirname, error)
```

Include Files

- mkl.fi, mkl_pardiso.f90

Description

This function deletes files generated with pardiso_handle_store_64that contain Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures.

Input Parameters

dirname CHARACTER

String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Output Parameters

error INTEGER

The error indicator.

error	Information
0	No error.
-10	Cannot delete files.
-12	Not supported in 32-bit library - routine is only supported in 64-bit libraries.

oneMKL PARDISO Parameters in Tabular Form

The following table lists all parameters of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO and gives their brief descriptions.

Parameter	Type	Description	Values	Comments	In/ Out
pt(64)	INTEGER on 32-bit architectures, INTEGER*8 on 64-bit architectures TYPE(MKL_PARDISO_HANDLE), INTENT(INOUT)	Solver internal data address pointer	0	Must be initialized with zeros and never be modified later	in/out
maxfct	INTEGER INTEGER, INTENT(IN)	Maximal number of factors in memory	>0	Generally used value is 1	in
mnum	INTEGER INTEGER, INTENT(IN)	The number of matrix (from 1 to *maxfct*) to solve	[1: *maxfct*]	Generally used value is 1	in
mtype	INTEGER INTEGER, INTENT(IN)	Matrix type	1 2 -2 3	Real and structurally symmetric Real and symmetric positive definite Real and symmetric indefinite Complex and structurally symmetric	in

Parameter	Type	Description	Values	Comments	In/ Out
			4	Complex and Hermitian positive definite	
			-4	Complex and Hermitian indefinite	
			6	Complex and symmetric matrix	
			11	Real and nonsymmetric matrix	
			13	Complex and nonsymmetric matrix	
phase	INTEGER INTEGER, INTENT(IN)	Controls the execution of the solver For *iparm*(36) > 0, phases 331, 332, and 333 perform a different decomposition. See the *phase* parameter of pardiso for details.	11	Analysis	in
			12	Analysis, numerical factorization	
			13	Analysis, numerical factorization, solve	
			22	Numerical factorization	
			23	Numerical factorization, solve	
			33	Solve, iterative refinement	
			331	*phase*=33, but only forward substitution	
			332	*phase*=33, but only diagonal substitution	
			333	*phase*=33, but only backward substitution	
			0	Release internal memory for L and U of the matrix number *mnum*	
			-1	Release all internal memory for all matrices	
n	INTEGER INTEGER, INTENT(IN)	Number of equations in the sparse linear system *A*X = B*	>0		in
a(*)	PARDISO_DATA_TYPE[1)] PARDISO_DATA_TYPE[1)], INTENT(IN)	Contains the non-zero elements of the coefficient matrix *A*	*	The size of *a* is the same as that of *ja*, and the coefficient matrix can be either real or complex. The matrix must be stored in the 3-array variation of compressed sparse row (CSR3) format with increasing values of *ja* for each row	in

Parameter	Type	Description	Values	Comments	In/ Out
ia(*n* + 1)	INTEGER INTEGER, INTENT(IN)	*rowIndex* array in CSR3 format	>=0	*ia*(*i*) gives the index of the element in array *a* that contains the first non-zero element from row *i* of *A*. The last element *ia*(*n*+1) (for one-based indexing) or *ia*(*n*) (for zero-based indexing) is taken to be equal to the number of non-zero elements in *A*, plus one. Note: *iparm*(35) indicates whether row/column indexing starts from 1 or 0.	in
ja(*)	INTEGER INTEGER, INTENT(IN)	*columns* array in CSR3 format	>=0	The column indices for each row of *A* must be sorted in increasing order. For structurally symmetric matrices zero diagonal elements must be stored in *a* and *ja*. Zero diagonal elements should be stored for symmetric matrices, although they are not required. For symmetric matrices, the solver needs only the upper triangular part of the system. Note: *iparm*(35) indicates whether row/column indexing starts from 1 or 0.	in
perm(*n*)	INTEGER INTEGER, INTENT(INOUT)	Holds the permutation vector of size *n*, specifies elements used for computing a partial solution, or specifies differing values of the input matrices for low rank update	>=0	You can apply your own fill-in reducing ordering (*iparm*(5) = 1) or return the permutation from the solver (*iparm*(5) = 2). Let $C = P*A*P^T$ be the permuted matrix. Row (column) *i* of *C* is the *perm*(*i*) row (column) of *A*. The numbering of the array must describe a permutation. To specify elements for a partial solution, set *iparm*(5) = 0, *iparm*(31) > 0, and *iparm*(36) = 0.	in/out

Parameter	Type	Description	Values	Comments	In/ Out
				To specify elements for a Schur complement, set *iparm*(5) = 0, *iparm*(31) = 0, and *iparm*(36) > 0. To specify values that differ in *A* for low rank update (see Low Rank Update), set *iparm*(39) = 1. The size of the array must be at least 2**ndiff* + 1, where *ndiff* is the number of values of *A* that are different. The values of *perm* should be: *perm* = {*ndiff*, *row_index1*, *column_index1*, *row_index2*, *column_index2*, ..., *row_index_ndiff*, *column_index_ndiff*} where *row_index_m* and *column_index_m* are the row and column indices of the *m*-th differing non-zero value in matrix *A*. The row and column index pairs can be in any order, but must use zero-based indexing regardless of the value of *iparm*(35). **NOTE** Unless you have specified low rank update, *iparm*(35) indicates whether row/column indexing starts from 1 or 0.	
nrhs	INTEGER INTEGER, INTENT(IN)	Number of right-hand sides that need to be solved for	>=0	Generally used value is 1 To obtain better Intel® oneAPI Math Kernel Library (oneMKL) PARDISO performance, during the numerical factorization phase you can provide the maximum number of right-hand sides, which can be used further during the solving phase.	in

Parameter	Type	Description	Values	Comments	In/ Out
iparm(64)	INTEGER INTEGER, INTENT(INOUT)	This array is used to pass various parameters to Intel® oneAPI Math Kernel Library (oneMKL) PARDISO and to return some useful information after execution of the solver (see pardiso iparm Parameter for more details)	*	If *iparm*(1)=0, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO fills*iparm*(2) through *iparm*(64) with default values and uses them.	in/out
msglvl	INTEGER INTEGER, INTENT(IN)	Message level information	0 1	Intel® oneAPI Math Kernel Library (oneMKL) PARDISO generates no output Intel® oneAPI Math Kernel Library (oneMKL) PARDISO prints statistical information	in
b(*n***nrhs*)	PARDISO_DATA_TYPE[1)] PARDISO_DATA_TYPE[1)], INTENT(INOUT)	Right-hand side vectors	*	On entry, contains the right-hand side vector/ matrix *B*, which is placed contiguously in memory. The *b*(i+(k-1)×*nrhs*) element must hold the *i*-th component of *k*-th right-hand side vector. Note that *b* is only accessed in the solution phase. On output, the array is replaced with the solution if *iparm*(6)=1.	in/out
x(*n***nrhs*)	PARDISO_DATA_TYPE[1)] PARDISO_DATA_TYPE[1)], INTENT(OUT)	Solution vectors	*	On output, if *iparm*(6)=0, contains solution vector/ matrix *X* which is placed contiguously in memory. The *x*(i+(k-1)×*nrhs*) element must hold the *i*-th component of *k*-th solution vector. Note that *x* is only accessed in the solution phase.	out
error	INTEGER INTEGER, INTENT(OUT)	Error indicator	0 -1 -2 -3	No error Input inconsistent Not enough memory Reordering problem	out

Parameter	Type	Description	Values	Comments	In/ Out
			-4	Zero pivot, numerical factorization or iterative refinement problem	
			-5	Unclassified (internal) error	
			-6	Reordering failed (matrix types 11 and 13 only)	
			-7	Diagonal matrix is singular	
			-8	32-bit integer overflow problem	
			-9	Not enough memory for OOC	
			-10	Problems with opening OOC temporary files	
			-11	Read/write problems with the OOC data file	

[1)] See description of `PARDISO_DATA_TYPE` in PARDISO_DATA_TYPE.

pardiso iparm Parameter

This table describes all individual components of the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO *iparm* parameter. Components which are not used must be initialized with 0. Default values are denoted with an asterisk (*).

Component	Description
iparm(1) input	Use default values.
	0 — *iparm*(2) - *iparm*(64) are filled with default values.
	≠0 — You must supply all values in components *iparm*(2) - *iparm*(64).
iparm(2) input	Fill-in reducing ordering for the input matrix.

Caution
You can control the parallel execution of the solver by explicitly setting the `MKL_NUM_THREADS` environment variable. If fewer OpenMP threads are available than specified, the execution may slow down instead of speeding up. If `MKL_NUM_THREADS` is not defined, then the solver uses all available processors.

0	The minimum degree algorithm [Li99].
2*	The nested dissection algorithm from the METIS package [Karypis98].
3	The parallel (OpenMP) version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Intel® oneAPI Math Kernel Library (oneMKL) PARDISO Phase 1 takes significant time.

NOTE
Setting *iparm*(2) = 3 prevents the use of CNR mode (*iparm*(34) > 0) because Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses dynamic parallelism.

Component	Description
iparm(3)	Reserved. Set to zero.
iparm(4) input	Preconditioned CGS/CG. This parameter controls preconditioned CGS [Sonn89] for nonsymmetric or structurally symmetric matrices and Conjugate-Gradients for symmetric matrices. *iparm*(4) has the form *iparm*(4) = 10**L*+*K*.

K=0	The factorization is always computed as required by *phase*.
K=1	CGS iteration replaces the computation of *LU*. The preconditioner is *LU* that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.
K=2	CGS iteration for symmetric positive definite matrices replaces the computation of LL^T. The preconditioner is LL^T that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.

The value *L* controls the stopping criterion of the Krylov Subspace iteration:

$\text{eps}_{CGS} = 10^{-L}$ is used in the stopping criterion

$||dx_i|| / ||dx_0|| < \text{eps}_{CGS}$

where $||dx_i|| = ||\text{inv}(L*U)*r_i||$ for $K = 1$ or $||dx_i|| = ||\text{inv}(L*L^T)*r_i||$ for $K = 2$ and r_i is the residue at iteration *i* of the preconditioned Krylov Subspace iteration.

A maximum number of 150 iterations is fixed with the assumption that the iteration will converge before consuming half the factorization time. Intermediate convergence rates and residue excursions are checked and can terminate the iteration process. If *phase* =23, then the factorization for a given *A* is automatically recomputed in cases where the Krylov Subspace iteration failed, and the corresponding direct solution is returned. Otherwise the solution from the preconditioned Krylov Subspace iteration is returned. Using *phase* =33 results in an error message (*error*=-4) if the stopping criteria for the Krylov Subspace iteration can not be reached. More information on the failure can be obtained from *iparm*(20).

The default is *iparm*(4)=0, and other values are only recommended for an advanced user. *iparm*(4) must be greater than or equal to zero.

Examples:

iparm(4)	Description
31	*LU*-preconditioned CGS iteration with a stopping criterion of 1.0E-3 for nonsymmetric matrices
61	*LU*-preconditioned CGS iteration with a stopping criterion of 1.0E-6 for nonsymmetric matrices
62	LL^T-preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric positive definite matrices

iparm(5) input	User permutation. This parameter controls whether user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms. Another use of this parameter is to control obtaining the fill-in reducing permutation vector calculated during the reordering stage of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

Component	Description
	This option is useful for testing reordering algorithms, adapting the code to special applications problems (for instance, to move zero diagonal elements to the end of $P*A*P^T$), or for using the permutation vector more than once for matrices with identical sparsity structures. For definition of the permutation, see the description of the *perm* parameter. **Caution** You can only set one of *iparm*(5), *iparm*(31), and *iparm*(36), so be sure that the *iparm*(31) (partial solution) and the *iparm*(36) (Schur complement) parameters are 0 if you set *iparm*(5).
	0* User permutation in the *perm* array is ignored.
	1 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the user supplied fill-in reducing permutation from the*perm* array. *iparm*(2) is ignored. **NOTE** Setting *iparm*(5) = 1 prevents use of a parallel algorithm for the solve step.
	2 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO returns the permutation vector computed at phase 1 in the*perm* array.
iparm(6) input	Write solution on *x*. **NOTE** The array *x* is always used.
	0* The array *x* contains the solution; right-hand side vector *b* is kept unchanged.
	1 The solver stores the solution on the right-hand side *b*.
iparm(7) output	Number of iterative refinement steps performed. Reports the number of iterative refinement steps that were actually performed during the solve step.
iparm(8) input	Iterative refinement step. On entry to the solve and iterative refinement step, *iparm*(8) must be set to the maximum number of iterative refinement steps that the solver performs. **NOTE** Perturbed pivots result in iterative refinement (independent of the value of *iparm*(8)) and the number of executed iterations is reported in *iparm*(7).
	0* The solver automatically performs two steps of iterative refinement when perturbed pivots are obtained during the numerical factorization.
	>0 Maximum number of iterative refinement steps that the solver performs. The solver performs not more than the absolute value of *iparm*(8) steps of iterative refinement. The solver might stop the process before the maximum number of steps if

Component	Description
	• a satisfactory level of accuracy of the solution in terms of backward error is achieved, • or if it determines that the required accuracy cannot be reached. In this case the solver returns -4 in the *error* parameter. The number of executed iterations is reported in *iparm*(7).
	<0 Maximum number of iterative refinement steps with a negative sign. Unlike the case above the accumulation of the residuum uses extended precision real and complex data types. **NOTE** Currently, this feature is only supported for sequential and OpenMP threading.
iparm(9) input	Tolerance level for the relative residual in the iterative refinement process. If set to a non-zero value, an additional criterion is used for stopping the iterative refinement: $\frac{\| r \|}{\| b \|} < 10^{-iparm(9)}$ If set to zero, default checks are used to determine when to stop the iterations (see iparm(8) description). **NOTE** Currently it is only used for iparm(24)=1 or 10 and OpenMP threading.
iparm(10) input	Pivoting perturbation. This parameter instructs Intel® oneAPI Math Kernel Library (oneMKL) PARDISO how to handle small pivots or zero pivots for nonsymmetric matrices (*mtype* =11 or *mtype* =13) and symmetric matrices (*mtype* =-2, *mtype* =-4, or *mtype* =6). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04]. Small pivots are perturbed with eps = $10^{-iparm(10)}$. The magnitude of the potential pivot is tested against a constant threshold of alpha = eps*$\|\|A2\|\|_{inf}$, where eps = $10^{(-iparm(10))}$, $A2 = P*P_{MPS}*D_r*A*D_c*P$, and $\|\|A2\|\|_{inf}$ is the infinity norm of the scaled and permuted matrix *A*. Any tiny pivots encountered during elimination are set to the sign (l_{II})*eps*$\|\|A2\|\|_{inf}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with eps = $10^{(-iparm(10))}$.
	13* The default value for nonsymmetric matrices(*mtype* =11, *mtype*=13), eps = 10^{-13}.
	8* The default value for symmetric indefinite matrices (*mtype* =-2, *mtype*=-4, *mtype*=6), eps = 10^{-8}.
iparm(11) input	Scaling vectors. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less than or equal to 1. This scaling method is applied only to nonsymmetric

Component	Description
	matrices (*mtype* = 11 or *mtype* = 13). The scaling can also be used for symmetric indefinite matrices (*mtype* = -2, *mtype* =-4, or *mtype* = 6) when the symmetric weighted matchings are applied (*iparm*(13) = 1). Use *iparm*(11) = 1 (scaling) and *iparm*(13) = 1 (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point problems. Note that in the analysis phase (*phase*=11) you must provide the numerical values of the matrix *A* in array *a* in case of scaling and symmetric weighted matching.
	0* Disable scaling. Default for symmetric indefinite matrices.
	1* Enable scaling. Default for nonsymmetric matrices. Scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied to nonsymmetric matrices (*mtype* = 11, *mtype* = 13). The scaling can also be used for symmetric indefinite matrices (*mtype* = -2, *mtype* = -4, *mtype* = 6) when the symmetric weighted matchings are applied (*iparm*(13) = 1). Note that in the analysis phase (*phase*=11) you must provide the numerical values of the matrix *A* in case of scaling.
iparm(12) input	Solve with transposed or conjugate transposed matrix *A*. **NOTE** For real matrices, the terms *transposed* and *conjugate transposed* are equivalent.
	0* Solve a linear system $AX = B$.
	1 Solve a conjugate transposed system $A^HX = B$ based on the factorization of the matrix *A*.
	2 Solve a transposed system $A^TX = B$ based on the factorization of the matrix *A*.
iparm(13) input	Improved accuracy using (non-) symmetric weighted matching. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to the factorization methods and complements the alternative of using more complete pivoting techniques during the numerical factorization.
	0* Disable matching. Default for symmetric indefinite matrices.
	1* Enable matching. Default for nonsymmetric matrices. Maximum weighted matching algorithm to permute large elements close to the diagonal. It is recommended to use *iparm*(11) = 1 (scaling) and *iparm*(13) = 1 (matching) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems. Note that in the analysis phase (*phase*=11) you must provide the numerical values of the matrix *A* in case of symmetric weighted matching.
iparm(14) output	Number of perturbed pivots.

Component	Description	
	After factorization, contains the number of perturbed pivots for the matrix types: 1, 3, 11, 13, -2, -4 and 6.	
iparm(15) output	Peak memory on symbolic factorization. The total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase. This value is only computed in phase 1.	
iparm(16) output	Permanent memory on symbolic factorization. Permanent memory from the analysis and symbolic factorization phase in kilobytes that the solver needs in the factorization and solve phases. This value is only computed in phase 1.	
iparm(17) output	Size of factors/Peak memory on numerical factorization and solution. This parameter provides the size in kilobytes of the total memory consumed by in-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO for internal floating point arrays. This parameter is computed in phase 1. See *iparm*(63) for the OOC mode. The total peak memory consumed by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO is max(*iparm*(15), *iparm*(16)+*iparm*(17))	
iparm(18) input/output	Report the number of non-zero elements in the factors.	
	<0	Enable reporting if *iparm*(18) < 0 on entry. The default value is -1.
	>=0	Disable reporting.
iparm(19) input/output	Report number of floating point operations (in 10^6 floating point operations) that are necessary to factor the matrix *A*.	
	<0	Enable report if *iparm*(19) < 0 on entry. This increases the reordering time.
	>=0 *	Disable report.
iparm(20) output	Report CG/CGS diagnostics.	
	>0	CGS succeeded, reports the number of completed iterations.
	<0	CG/CGS failed (*error*=-4 after the solution phase). If *phase*= 23, then the factors *L* and *U* are recomputed for the matrix *A* and the error flag *error*=0 in case of a successful factorization. If *phase* = 33, then *error* = -4 signals failure. *iparm*(20)= - it_cgs*10 - cgs_error. Possible values of cgs_error: 1 - fluctuations of the residuum are too large 2 - $\|\|dx_{max\_it\_cgs/2}\|\|$ is too large (slow convergence) 3 - stopping criterion is not reached at max_it_cgs 4 - perturbed pivots caused iterative refinement 5 - factorization is too fast for this matrix. It is better to use the factorization method with *iparm*(4) = 0
iparm(21) input	Pivoting for symmetric indefinite matrices.	

Component	Description
	NOTE Use *iparm*(11) = 1 (scaling) and *iparm*(13) = 1 (matchings) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems.
	0 — Apply 1x1 diagonal pivoting during the factorization process.
	1* — Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of *mtype*=-2, *mtype*=-4, or *mtype*=6.
	2 — Apply 1x1 diagonal pivoting during the factorization process. Using this value is the same as using *iparm*(21) = 0 except that the solve step does not automatically make iterative refinements when perturbed pivots are obtained during numerical factorization. The number of iterations is limited to the number of iterative refinements specified by *iparm*(8) (0 by default).
	3 — Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of *mtype*=-2, *mtype*=-4, or *mtype*=6. Using this value is the same as using *iparm*(21) = 1 except that the solve step does not automatically make iterative refinements when perturbed pivots are obtained during numerical factorization. The number of iterations is limited to the number of iterative refinements specified by *iparm*(8) (0 by default).
iparm(22) output	Inertia: number of positive eigenvalues. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO reports the number of positive eigenvalues for symmetric indefinite matrices.
iparm(23) output	Inertia: number of negative eigenvalues. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO reports the number of negative eigenvalues for symmetric indefinite matrices.
iparm(24) input	Parallel factorization control.
	0* — Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the classic algorithm for factorization.
	1 — Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses a two-level factorization algorithm. This algorithm generally improves scalability in case of parallel factorization on many OpenMP threads (more than eight). **NOTE** Disable *iparm*(11) (scaling) and *iparm*(13) = 1 (matching) when using the two-level factorization algorithm. Otherwise Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the classic factorization algorithm.
	10 — Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses an improved two-level factorization algorithm for nonsymmetric matrices.
iparm(25) input	Parallel forward/backward solve control.
	0* — Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the following strategy for parallelizing the solving step: In the case of the one right-hand side, the parallelization will be performed by partitioning the matrix.

Component	Description	
		Otherwise, the parallelization will be over the right-hand sides. This feature is available only for in-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (see *iparm*(60)).
	1	Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the sequential forward and backward solve.
	2	Independent from the number of the right-hand sides, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the parallel algorithm based on the matrix partitioning. This feature is available only for in-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (see *iparm*(60)).
iparm(26)	Reserved. Set to zero.	
iparm(27) input	Matrix checker.	
	0*	Intel® oneAPI Math Kernel Library (oneMKL) PARDISO does not check the sparse matrix representation for errors.
	1	Intel® oneAPI Math Kernel Library (oneMKL) PARDISO checks integer arrays *ia* and *ja*. In particular, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO checks whether column indices are sorted in increasing order within each row.
iparm(28) input	Single or double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. See *iparm*(8) for information on controlling the precision of the refinement steps. **Important** The *iparm*(28) value is stored in the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO handle between Intel® oneAPI Math Kernel Library (oneMKL) PARDISO calls, so the precision mode can be changed only during phase 1.	
	0*	Input arrays (*a*, *x* and *b*) and all internal arrays must be presented in double precision.
	1	Input arrays (*a*, *x* and *b*) must be presented in single precision. In this case all internal computations are performed in single precision.
iparm(29)	Reserved. Set to zero.	
iparm(30) output	Number of zero or negative pivots. If Intel® oneAPI Math Kernel Library (oneMKL) PARDISO detects zero or negative pivot for *mtype*=2 or *mtype*=4 matrix types, the factorization is stopped. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO returns immediately with an *error* = -4, and *iparm*(30) reports the number of the equation where the zero or negative pivot is detected. Note: The returned value can be different for the parallel and sequential version in case of several zero/negative pivots.	
iparm(31) input	Partial solve and computing selected components of the solution vectors. This parameter controls the solve step of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. It can be used if only a few components of the solution vectors are needed or if you want to reduce the computation cost at the solve step by utilizing the sparsity of the right-hand sides. To use this option the input permutation vector define *perm* so	

<table>
<tr><th>Component</th><th>Description</th></tr>
<tr><td></td><td>
that when perm(i) = 1 it means that either the i-th component in the right-hand sides is nonzero, or the i-th component in the solution vectors is computed, or both, depending on the value of iparm(31).

The permutation vector permmust be present in all phases of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO software. At the reordering step, the software overwrites the input vectorperm by a permutation vector used by the software at the factorization and solver step. If m is the number of components such that perm(i) = 1, then the last m components of the output vector perm are a set of the indices i satisfying the condition perm(i) = 1 on input.

NOTE
Turning on this option often increases the time used by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO for factorization and reordering steps, but it can reduce the time required for the solver step.

Important
You can use this feature for both in-core and out-of-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO as long as iparm[23]=1. Otherwise, you cannot use partial solve for out-of-core mode and you will need to setiparm(60)=0 for in-core mode. Set the parameters iparm(8) (iterative refinement steps), iparm(4) (preconditioned CGS), iparm(5) (user permutation), and iparm(36) (Schur complement) to 0 as well.

<table>
<tr><td>0*</td><td>Disables this option.</td></tr>
<tr><td>1</td><td>it is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector perm is defined so that perm(i) = 1 means that the (i)-th component in the right-hand sides is nonzero. In this case Intel® oneAPI Math Kernel Library (oneMKL) PARDISO only uses the non-zero components of the right-hand side vectors and computes only corresponding components in the solution vectors. That means thei-th component in the solution vectors is only computed if perm(i) = 1.</td></tr>
<tr><td>2</td><td>It is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector perm is defined so that perm(i) = 1 means that the i-th component in the right-hand sides is nonzero.

Unlike for iparm(31)=1, all components of the solution vector are computed for this setting and all components of the right-hand sides are used. Because all components are used, for iparm(31)=2 you must set the i-th component of the right-hand sides to zero explicitly if perm(i) is not equal to 1.</td></tr>
<tr><td>3</td><td>Selected components of the solution vectors are computed. The perm array is not related to the right-hand sides and it only indicates which components of the solution vectors should be computed. In this case perm(i) = 1 means that the i-th component in the solution vectors is computed.</td></tr>
</table>

input</td><td>Optimal number of OpenMP threads for conditional numerical reproducibility (CNR) mode.

Intel® oneAPI Math Kernel Library (oneMKL) PARDISO reads the value ofiparm(34) during the analysis phase (phase 1), so you cannot change it later.</td></tr>
</table>

Component	Description
	Because Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses C random number generator facilities during the analysis phase (phase 1) you must take these precautions to get numerically reproducible results: • Do not alter the states of the random number generators. • Do not run multiple instances of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO in parallel in the analysis phase (phase 1). **NOTE** CNR is only available for the in-core version of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO and the non-parallel version of the nested dissection algorithm. You must also: • set *iparm*(60) to 0 in order to use the in-core version, • not set *iparm*(2) to 3 in order to not use the parallel version of the nested dissection algorithm. Otherwise Intel® oneAPI Math Kernel Library (oneMKL) PARDISO does not produce numerically repeatable results even if CNR is enabled for Intel® oneAPI Math Kernel Library (oneMKL) using the functionality described in Support Functions for CNR.
	0* — CNR mode for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO is enabled only if it is enabled for Intel® oneAPI Math Kernel Library (oneMKL) using the functionality described in Support Functions for CNR and the in-core version is used. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO determines the optimal number of OpenMP threads automatically, and produces numerically reproducible results regardless of the number of threads.
	>0 — CNR mode is enabled for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO if in-core version is used and the optimal number of OpenMP threads for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO to rely on is defined by the value of *iparm*(34). You can use *iparm*(34) to enable CNR mode independent from other Intel® oneAPI Math Kernel Library (oneMKL) domains. To get the best performance, set *iparm*(34) to the actual number of hardware threads dedicated for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. Setting *iparm*(34) to fewer OpenMP threads than the maximum number of them in use reduces the scalability of the problem being solved. Setting *iparm*(34) to more threads than are available can reduce the performance of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.
iparm(35) input	One- or zero-based indexing of columns and rows. **NOTE** Schur complement may be inaccurate or incorrect if pivots are detected. Please, check the output of *iparm*(29) .
	0* — One-based indexing: columns and rows indexing in arrays *ia*, *ja*, and *perm* starts from 1 (Fortran-style indexing).
	1 — Zero-based indexing: columns and rows indexing in arrays *ia*, *ja*, and *perm* starts from 0 (C-style indexing).
iparm(36) input/output	Schur complement matrix computation control. To calculate this matrix, you must set the input permutation vector *perm* to a set of indexes such that when *perm*(*i*) = 1, the *i*-th element of the initial matrix is an element of the Schur matrix.

Component	Description
	Caution You can only set one of *iparm*(5), *iparm*(31), and *iparm*(36), so be sure that the *iparm*(5) (user permutation) and the *iparm*(31) (partial solution) parameters are 0 if you set *iparm*(36).
	0* — Do not compute Schur complement.
	1 — Compute Schur complement matrix as part of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO factorization step and return it in the solution vector. **NOTE** This option only computes the Schur complement matrix, and does not calculate factorization arrays.
	2 — Compute Schur complement matrix as part of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO factorization step and return it in the solution vector. Since this option calculates factorization arrays you can use it to launch partial or full solution of the entire problem after the factorization step.
	-1 — Same as *iparm*(36) equals 1, but the Schur complement matrix is provided in 3-array CSR sparse format. Use in combination with pardiso_export. After reordering stage of MKL PARDISO, *iparm*(36) contains number of nonzero elements for Schur complement matrix. Set it once again before calling the factorization phase. **NOTE** This option is available only when *iparm*(24) is not equal to 0.
	-2 — Same as *iparm*(36) equals 2, but the Schur complement matrix is provided in 3-array CSR sparse format. Use in combination with pardiso_export. After reordering stage of MKL PARDISO, *iparm*(36) contains number of nonzero elements for Schur complement matrix. Set it once again before calling the factorization phase. **NOTE** This option is available only when *iparm*(24) is not equal to 0.
iparm(37) input	Format for matrix storage.
	0* — Use CSR format (see Three Array Variation of CSR Format) for matrix storage.
	> 0 — Use BSR format (see Three Array Variation of BSR Format) for matrix storage with blocks of size *iparm*(37).

Component	Description
	NOTE Intel® oneAPI Math Kernel Library (oneMKL) does not support BSR format in these cases: • *iparm*(11) > 0: Scaling vectors • *iparm*(13) > 0: Weighted matching • *iparm*(31) > 0: Partial solution • *iparm*(36) > 0: Schur complement • *iparm*(56) > 0: Pivoting control • *iparm*(60) > 0: OOC Intel® oneAPI Math Kernel Library (oneMKL) PARDISO
	< 0 — Convert supplied matrix to variable BSR (VBSR) format (see Sparse Data Storage) for matrix storage. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO analyzes the matrix provided in CSR3 format and converts it to an internal VBSR format. Set *iparm*(37) = −*t*, 0 < *t*≤ 100. **NOTE** Intel® oneAPI Math Kernel Library (oneMKL) supports only the VBSR format for real and symmetric positive definite or indefinite matrices (*mtype* = 2 or *mtype*= -2). Intel® oneAPI Math Kernel Library (oneMKL) does not support VBSR format in these cases: • *iparm*(11) > 0: Scaling vectors • *iparm*(13) > 0: Weighted matching • *iparm*(56) > 0: Pivoting control
	NOTEIntel® oneAPI Math Kernel Library (oneMKL) supports these features for all matrix types as long as *iparm*(24) =1: • *iparm*(31) > 0: Partial solution • *iparm*(36) > 0: Schur complement • *iparm*(60) > 0: OOC Intel® oneAPI Math Kernel Library (oneMKL) PARDISO
iparm(38)	Reserved. Set to zero.
iparm(39)	Enable low rank update (see Low Rank Update) to accelerate factorization for multiple matrices with identical structure and similar values.
	0* — Do not use low rank update functionality.
	1 — Use low rank update functionality. You must also set *iparm*(24) = 10 and provide a list of changed values in the *perm* array. This option requires the default settings of *iparm*(4), *iparm*(5), *iparm*(6), *iparm*(12), *iparm*(28), *iparm*(31), *iparm*(36), *iparm*(37), *iparm*(56), and *iparm*(60) as well.
iparm(40) - *iparm*(42)	Reserved. Set to zero.
iparm(43)	Control parameter for the computation of the diagonal of inverse matrix.
	0* — Do not compute the diagonal of inverse matrix.

Component	Description	
	1	Intel® oneAPI Math Kernel Library (oneMKL) PARDISO computes the diagonal of the inverse matrix during the factorization phase. This feature is only available with two-level factorization algorithm (*iparm*(24) = 1) and real symmetric matrices (*mtype* = 2 or *mtype* = -2). The diagonal is returned in the solution vector.
iparm(44) - *iparm*(55)	Reserved. Set to zero.	
iparm(56)	Diagonal and pivoting control.	
	0*	Internal function used to work with pivot and calculation of diagonal arrays turned off.
	1	You can use the mkl_pardiso_pivot callback routine to control pivot elements which appear during numerical factorization. Additionally, you can obtain the elements of initial matrix and factorized matrices after the pardiso factorization step diagonal using the pardiso_getdiagroutine. This parameter can be turned on only in the in-core version of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.
iparm(57) - *iparm*(59)	Reserved. Set to zero.	
iparm(60) input	Intel® oneAPI Math Kernel Library (oneMKL) PARDISO mode. *iparm*(60) switches between in-core (IC) and out-of-core (OOC) Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. OOC can solve very large problems by holding the matrix factors in files on the disk, which requires a reduced amount of main memory compared to IC. Unless you are operating in sequential mode, you can switch between IC and OOC modes after the reordering phase. However, you can get better Intel® oneAPI Math Kernel Library (oneMKL) PARDISO performance by setting*iparm*(60) before the reordering phase. The amount of memory used in OOC mode depends on the number of OpenMP threads. **Warning** Do not increase the number of OpenMP threads used for cluster_sparse_solver between the first call and the factorization or solution phase. Because the minimum amount of memory required for out-of-core execution depends on the number of OpenMP threads, increasing it after the initial call can cause incorrect results.	
	0*	IC mode.
	1	IC mode is used if the total amount of RAM (in megabytes) needed for storing the matrix factors is less than sum of two values of the environment variables: MKL_PARDISO_OOC_MAX_CORE_SIZE (default value 2000 MB) and MKL_PARDISO_OOC_MAX_SWAP_SIZE (default value 0 MB); otherwise OOC mode is used. In this case amount of RAM used by OOC mode cannot exceed the value of MKL_PARDISO_OOC_MAX_CORE_SIZE. If the total peak memory needed for storing the local arrays is more than MKL_PARDISO_OOC_MAX_CORE_SIZE, increase MKL_PARDISO_OOC_MAX_CORE_SIZE if possible.

Component	Description
	NOTE Conditional numerical reproducibility (CNR) is not supported for this mode.
	2 OOC mode. The OOC mode can solve very large problems by holding the matrix factors in files on the disk. Hence the amount of RAM required by OOC mode is significantly reduced compared to IC mode. If the total peak memory needed for storing the local arrays is more than `MKL_PARDISO_OOC_MAX_CORE_SIZE`, increase `MKL_PARDISO_OOC_MAX_CORE_SIZE` if possible. To obtain better Intel® oneAPI Math Kernel Library (oneMKL) PARDISO performance, during the numerical factorization phase you can provide the maximum number of right-hand sides, which can be used further during the solving phase. Refer to How to use Intel® MKL OOC PARDISO and Storage of Matrices for more details about OOC.
iparm(61) - *iparm*(62)	Reserved. Set to zero.
iparm(63) output	Size of the minimum OOC memory for numerical factorization and solution. This parameter provides the size in kilobytes of the minimum memory required by OOC Intel® oneAPI Math Kernel Library (oneMKL) PARDISO for internal floating point arrays. This parameter is computed in phase 1. Total peak memory consumption of OOC Intel® oneAPI Math Kernel Library (oneMKL) PARDISO can be estimated as max(*iparm*(15), *iparm*(16) + *iparm*(63)).
iparm(64)	Reserved. Set to zero.

NOTE
Generally in sparse matrices, components which are equal to zero can be considered non-zero if necessary. For example, in order to make a matrix structurally symmetric, elements which are zero can be considered non-zero. See Sparse Matrix Storage Formats for an example.

Notice revision #20201201

PARDISO_DATA_TYPE

The following table lists the values of `PARDISO_DATA_TYPE` depending on the matrix types and values of the parameter *iparm*(28).

Data type value	Matrix type *mtype*	*iparm*(28)	comments
DOUBLE PRECISION	1, 2, -2, 11	0	Real matrices, do
REAL		1	Real matrices, sin
DOUBLE COMPLEX	3, 6, 13, 4, -4	0	Complex matrices precision
COMPLEX		1	Complex matrices precision

Parallel Direct Sparse Solver for Clusters Interface

The Parallel Direct Sparse Solver for Clusters Interface solves large linear systems of equations with sparse matrices on clusters. It is

- high performing
- robust
- memory efficient
- easy to use

A hybrid implementation combines Message Passing Interface (MPI) technology for data exchange between parallel tasks (processes) running on different nodes, and OpenMP* technology for parallelism inside each node of the cluster. This approach effectively uses modern hardware resources such as clusters consisting of nodes with multi-core processors. The solver code is optimized for the latest Intel processors, but also performs well on clusters consisting of non-Intel processors.

Code examples are available in the Intel® oneAPI Math Kernel Library (oneMKL) installation`examples` directory.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Parallel Direct Sparse Solver for Clusters Interface Algorithm

Parallel Direct Sparse Solver for Clusters Interface solves a set of sparse linear equations

$A*X = B$

with multiple right-hand sides using a distributed LU, LL^T , LDL^T or $LDL*$ factorization, where A is an n-by-n matrix, and X and B are n-by-$nrhs$ matrices.

The solution comprises four tasks:

- analysis and symbolic factorization;
- numerical factorization;
- forward and backward substitution including iterative refinement;
- termination to release all internal solver memory.

The solver first computes a symmetric fill-in reducing permutation P based on the nested dissection algorithm from the METIS package [Karypis98](included with Intel® oneAPI Math Kernel Library (oneMKL)), followed by the Cholesky or other type of factorization (depending on matrix type)[Schenk00-2] of PAP^T. The solver uses either diagonal pivoting, or 1x1 and 2x2 Bunch and Kaufman pivoting for symmetric indefinite or Hermitian matrices before finding an approximation of X by forward and backward substitution and iterative refinement.

The initial matrix *A* is perturbed whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal blocks. One or two passes of iterative refinement may be required to correct the effect of the perturbations. This restricted notion of pivoting with iterative refinement is effective for highly indefinite symmetric systems. For a large set of matrices from different application areas, the accuracy of this method is comparable to a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Parallel Direct Sparse Solver for Clusters additionally improves the pivoting accuracy by applying symmetric weighted matching algorithms. These methods identify large entries in the coefficient matrix *A* that, if permuted close to the diagonal, enable the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. The methods are based on maximum weighted matching and improve the quality of the factor in a complementary way to the alternative idea of using more complete pivoting techniques.

Parallel Direct Sparse Solver for Clusters Interface Matrix Storage

The sparse data storage in the Parallel Direct Sparse Solver for Clusters Interface follows the scheme described in the Sparse Matrix Storage Formats section using the variable *ja* for *columns*, *ia* for *rowIndex*, and *a* for *values*. Column indices *ja* must be in increasing order per row.

When an input data structure is not accessed in a call, a NULL pointer or any valid address can be passed as a placeholder for that argument.

Algorithm Parallelization and Data Distribution

Intel® oneAPI Math Kernel Library (oneMKL) Parallel Direct Sparse Solver for Clusters enables parallel execution of the solution algorithm with efficient data distribution.

The master MPI process performs the symbolic factorization phase to represent matrix *A* as computational tree. Then matrix *A* is divided among all MPI processes in a one-dimensional manner. The same distribution is used for *L-factor* (the lower triangular matrix in Cholesky decomposition). Matrix *A* and all required internal data are broadcast to subordinate MPI processes. Each MPI process fills in its own parts of *L-factor* with initial values of the matrix *A*.

Parallel Direct Sparse Solver for Clusters Interface computes all independent parts of *L-factor* completely in parallel. When a block of the factor must be updated by other blocks, these updates are independently passed to a temporary array on each updating MPI process. It further gathers the result into an updated block using the `MPI_Reduce()` routine. The computations within an MPI process are dynamically divided among OpenMP threads using pipelining parallelism with a combination of left- and right-looking techniques similar to those of the PARDISO* software. Level 3 BLAS operations from Intel® oneAPI Math Kernel Library (oneMKL) ensure highly efficient performance of block-to-block update operations.

During forward/backward substitutions, respective Right Hand Side (RHS) parts are distributed among all MPI processes. All these processes participate in the computation of the solution. Finally, the solution is gathered on the master MPI process.

This approach demonstrates good scalability on clusters with Infiniband* technology. Another advantage of the approach is the effective distribution of *L-factor* among cluster nodes. This enables the solution of tasks with a much higher number of non-zero elements than it is possible with any Symmetric Multiprocessing (SMP) in-core direct solver.

The algorithm ensures that the memory required to keep internal data on each MPI process is decreased when the number of MPI processes in a run increases. However, the solver requires that matrix *A* and some other internal arrays completely fit into the memory of each MPI process.

To get the best performance, run one MPI process per physical node and set the number of OpenMP* threads per node equal to the number of physical cores on the node.

NOTE
Instead of calling `MPI_Init()`, initialize MPI with `MPI_Init_thread()` and set the MPI threading level to `MPI_THREAD_FUNNELED` or higher. For details, see the code examples in *<install_dir>*`/examples`.

cluster_sparse_solver

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.

Syntax

`call cluster_sparse_solver (`*`pt, maxfct, mnum, mtype, phase, n, a, ia, ja, perm, nrhs, iparm, msglvl, b, x, comm, error`*`)`

Include Files

- Fortran: `mkl_cluster_sparse_solver.f77`
- Fortran 90: `mkl_cluster_sparse_solver.f90`

Description

The routine `cluster_sparse_solver` calculates the solution of a set of sparse linear equations

```
A*X = B
```

with single or multiple right-hand sides, using a parallel *LU*, *LDL*, or LL^T factorization, where *A* is an *n*-by-*n* matrix, and *X* and *B* are *n*-by-*nrhs* vectors or matrices.

NOTE
This routine supports the Progress Routine feature. See Progress Function for details.

Input Parameters

NOTE
Most of the input parameters (except for the *pt*, *phase*, and *comm* parameters and, for the distributed format, the *a*, *ia*, and *ja* arrays) must be set on the master MPI process only, and ignored on other processes. Other MPI processes get all required data from the master MPI process using the MPI communicator, *comm*.

pt

`INTEGER*8` for 64-bit architectures

Array of size 64.

Handle to internal data structure. The entries must be set to zero before the first call to `cluster_sparse_solver`.

Caution
After the first call to `cluster_sparse_solver` do not modify *pt*, as that could cause a serious memory leak.

maxfct

`INTEGER`

Ignored; assumed equal to 1.

mnum INTEGER

Ignored; assumed equal to 1.

mtype INTEGER

Defines the matrix type, which influences the pivoting method. The Parallel Direct Sparse Solver for Clusters solver supports the following matrices:

1	real and structurally symmetric
2	real and symmetric positive definite
-2	real and symmetric indefinite
3	complex and structurally symmetric
4	complex and Hermitian positive definite
-4	complex and Hermitian indefinite
6	complex and symmetric
11	real and nonsymmetric
13	complex and nonsymmetric

phase INTEGER

Controls the execution of the solver. Usually it is a two- or three-digit integer. The first digit indicates the starting phase of execution and the second digit indicates the ending phase. Parallel Direct Sparse Solver for Clusters has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including optional iterative refinement
- Memory release (*phase*= -1)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

phase	**Solver Execution Steps**
11	Analysis
12	Analysis, numerical factorization
13	Analysis, numerical factorization, solve, iterative refinement
22	Numerical factorization
23	Numerical factorization, solve, iterative refinement
33	Solve, iterative refinement
-1	Release all internal memory for all matrices

n

INTEGER

Number of equations in the sparse linear systems of equations *A*X = B*. Constraint: *n* > 0.

a

DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision Parallel Direct Sparse Solver for Clusters Interface (*iparm*(28) =0)

REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision Parallel Direct Sparse Solver for Clusters Interface (*iparm*(28) =1)

DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision Parallel Direct Sparse Solver for Clusters Interface (*iparm*(28) =0)

COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision Parallel Direct Sparse Solver for Clusters Interface (*iparm*(28) =1)

Array. Contains the non-zero elements of the coefficient matrix *A* corresponding to the indices in *ja*. The coefficient matrix can be either real or complex. The matrix must be stored in the three-array variant of the compressed sparse row (CSR3) or in the three-array variant of the block compressed sparse row (BSR3) format, and the matrix must be stored with increasing values of *ja* for each row.

For CSR3 format, the size of *a* is the same as that of *ja*. Refer to the *values* array description in Three Array Variation of CSR Format for more details.

For BSR3 format the size of *a* is the size of *ja* multiplied by the square of the block size. Refer to the *values* array description in Three Array Variation of BSR Format for more details.

NOTE
For centralized input (*iparm*(40)=0), provide the *a* array for the master MPI process only. For distributed assembled input (*iparm*(40)=1 or *iparm*(40)=2), provide it for all MPI processes.

Important
The column indices of non-zero elements of each row of the matrix *A* must be stored in increasing order.

ia

INTEGER

For CSR3 format, *ia*(*i*) (*i*≤*n*) points to the first column index of row *i* in the array *ja*. That is, *ia*(*i*) gives the index of the element in array *a* that contains the first non-zero element from row *i* of *A*. The last element *ia*(*n* +1) is taken to be equal to the number of non-zero elements in *A*, plus one. Refer to *rowIndex* array description in Three Array Variation of CSR Format for more details.

For BSR3 format, `ia(i)` (`i≤n`) points to the first column index of row *i* in the array `ja`. That is, `ia(i)` gives the index of the element in array `a` that contains the first non-zero block from row *i* of *A*. The last element `ia(n+1)` is taken to be equal to the number of non-zero blcoks in *A*, plus one. Refer to *rowIndex* array description in Three Array Variation of BSR Format for more details.

The array `ia` is accessed in all phases of the solution process.

Indexing of `ia` is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter `iparm(35)`. For zero-based indexing, the last element `ia(n+1)` is assumed to be equal to the number of non-zero elements in matrix *A*.

NOTE
For centralized input (`iparm(40)=0`), provide the `ia` array at the master MPI process only. For distributed assembled input (`iparm(40)=1` or `iparm(40)=2`), provide it at all MPI processes.

ja

INTEGER

For CSR3 format, array `ja` contains column indices of the sparse matrix *A*. It is important that the indices are in increasing order per row. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in Three Array Variation of CSR Format.

For BSR3 format, array `ja` contains column indices of the sparse matrix *A*. It is important that the indices are in increasing order per row. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in Three Array Variation of BSR Format.

The array `ja` is accessed in all phases of the solution process.

Indexing of `ja` is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter `iparm(35)`.

NOTE
For centralized input (`iparm(40)=0`), provide the `ja` array at the master MPI process only. For distributed assembled input (`iparm(40)=1` or `iparm(40)=2`), provide it at all MPI processes.

perm

INTEGER

Ignored.

nrhs

INTEGER

Number of right-hand sides that need to be solved for.

iparm

INTEGER

Array, size `64`. This array is used to pass various parameters to Parallel Direct Sparse Solver for Clusters Interface and to return some useful information after execution of the solver.

See cluster_sparse_solver iparm Parameter for more details about the *iparm* parameters.

msglvl

INTEGER

Message level information. If *msglvl* = 0 then cluster_sparse_solver generates no output, if *msglvl* = 1 the solver prints statistical information to the screen.

Statistics include information such as the number of non-zero elements in *L-factor* and the timing for each phase.

Set *msglvl* = 1 if you report a problem with the solver, since the additional information provided can facilitate a solution.

b

DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision Parallel Direct Sparse Solver for Clusters (*iparm*(28)=0)

REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision Parallel Direct Sparse Solver for Clusters (*iparm*(28)=1)

DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision Parallel Direct Sparse Solver for Clusters (*iparm*(28)=0)

COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision Parallel Direct Sparse Solver for Clusters (*iparm*(28)=1)

Array, size (*n*, *nrhs*). On entry, contains the right-hand side vector/matrix *B*, which is placed in memory contiguously. The *b*(i+(k-1)×*nrhs*) must hold the i-th component of k-th right-hand side vector. Note that *b* is only accessed in the solution phase.

comm

INTEGER

MPI communicator. The solver uses the Fortran MPI communicator internally.

Output Parameters

pt

Handle to internal data structure.

perm

Ignored.

iparm

On output, some *iparm* values report information such as the numbers of non-zero elements in the factors.

See cluster_sparse_solver iparm Parameter for more details about the *iparm* parameters.

b

On output, the array is replaced with the solution if *iparm*(6) = 1.

x

DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision Parallel Direct Sparse Solver for Clusters (*iparm*(28)=0)

REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision Parallel Direct Sparse Solver for Clusters (*iparm*(28)=1)

DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision Parallel Direct Sparse Solver for Clusters (*iparm*(28)=0)

COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision Parallel Direct Sparse Solver for Clusters (*iparm*(28)=1)

Array, size (*n*, *nrhs*). If *iparm*(6)=0 it contains solution vector/matrix *X*, which is placed contiguously in memory. The *x*(i+(k-1)× *n*) element must hold the i-th component of the k-th solution vector. Note that *x* is only accessed in the solution phase.

error

INTEGER

The error indicator according to the below table:

error	**Information**
0	no error
-1	input inconsistent
-2	not enough memory
-3	reordering problem
-4	Zero pivot, numerical factorization or iterative refinement problem. If the error appears during the solution phase, try to change the pivoting perturbation (*iparm*(10)) and also increase the number of iterative refinement steps. If it does not help, consider changing the scaling, matching and pivoting options (*iparm*(11), *iparm*(13), *iparm*(21))
-5	unclassified (internal) error
-6	reordering failed (matrix types 11 and 13 only)
-7	diagonal matrix is singular
-8	32-bit integer overflow problem
-9	not enough memory for OOC
-10	error opening OOC files
-11	read/write error with OOC files

cluster_sparse_solver_64

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.

Syntax

call cluster_sparse_solver_64 (*pt*, *maxfct*, *mnum*, *mtype*, *phase*, *n*, *a*, *ia*, *ja*, *perm*, *nrhs*, *iparm*, *msglvl*, *b*, *x*, *comm*, *error*)

Include Files

- Fortran: `mkl_cluster_sparse_solver.f77`
- Fortran 90: `mkl_cluster_sparse_solver.f90`

Description

The routine `cluster_sparse_solver_64` is an alternative ILP64 (64-bit integer) version of the cluster_sparse_solver routine (see the Description section for more details). The interface of `cluster_sparse_solver_64` is the same as the interface of `cluster_sparse_solver`, but it accepts and returns all INTEGER data as `INTEGER*8`.

Use `cluster_sparse_solver_64` when `cluster_sparse_solver`for solving large matrices (with the number of non-zero elements on the order of 500 million or more). You can use it together with the usual LP64 interfaces for the rest of Intel® oneAPI Math Kernel Library (oneMKL) functionality. In other words, if you use 64-bit integer version (`cluster_sparse_solver_64`), you do not need to re-link your applications with ILP64 libraries. Take into account that `cluster_sparse_solver_64` may perform slower than regular `cluster_sparse_solver` on the reordering and symbolic factorization phase.

NOTE
`cluster_sparse_solver_64` is supported only in the 64-bit libraries. If `cluster_sparse_solver_64` is called from the 32-bit libraries, it returns *error* =-12.

NOTE
This routine supports the Progress Routine feature. See Progress Function for details.

Input Parameters

The input parameters of `cluster_sparse_solver_64` are the same as the input parameters of `cluster_sparse_solver`, but `cluster_sparse_solver_64` accepts all INTEGER data as `INTEGER*8`.

Output Parameters

The output parameters of `cluster_sparse_solver_64` are the same as the output parameters of `cluster_sparse_solver`, but `cluster_sparse_solver_64` returns all INTEGER data as `INTEGER*8`.

cluster_sparse_solver_get_csr_size

Computes the (local) number of rows and (local) number of nonzero entries for (distributed) CSR data corresponding to the provided name.

Syntax

`call cluster_sparse_solver_get_csr_size (pt, name, local_nrows, local_nnz, comm, error)`

Include Files

- `mkl_cluster_sparse_solver.f90`

Description

This routine uses the internal data created during the factorization phase of `cluster_sparse_solver` for matrix *A*. The routine then:

- Computes the local number of rows and the local number of nonzeros for CSR data that correspond to the provided *name*
- Returns the computed values in *local_nrows* and *local_nnz*

It is assumed that the CSR data defined by the *name* will be distributed in the same way as the matrix *A* (as defined by *iparm*(40)) used in cluster_sparse_solver.

The returned values can be used for allocating CSR arrays for factors *L* and *U*, and also for allocating arrays for permutations *P* and *Q*, or scaling matrix *D* which can then be used with cluster_sparse_solver_set_csr_ptrs or cluster_sparse_solver_set_ptr for exporting corresponding data via cluster_sparse_solver_export.

NOTE
Only call this routine after the factorization phase (*phase*=22) of the cluster_sparse_solver has been called. Neither *pt*, nor *iparm* should be changed after the preceding call to cluster_sparse_solver.

Input Parameters

pt

INTEGER*8 for 64-bit architectures

Array with size of 64.

Handle to internal data structure used in the prior calls to cluster_sparse_solver.

Caution
Do not modify *pt* after the calls to cluster_sparse_solver.

name

INTEGER

Specifies CSR data for which the output values are computed.

SPARSE_PTLUQT_L	Factor *L* from $P*A*Q=L*U$.
SPARSE_PTLUQT_U	Factor *U* from $P*A*Q=L*U$.
SPARSE_DPTLUQT_L	Factor *L* from $P*\ (D^{-1}A)*Q=L*U$.
SPARSE_DPTLUQT_U	Factor *U* from $P*\ (D^{-1}A)*Q=L*U$.

comm

INTEGER*4

MPI communicator. The solver uses the Fortran MPI communicator internally.

Output Parameters

local_nrows

INTEGER

The local number of rows for the CSR data which correspond to the *name*.

local_nnz

INTEGER

The local number of nonzero entries for the CSR data which correspond to the *name*.

error INTEGER

The error indicator:

error	Information
0	no error
-1	*pt* is a null pointer
-2	invalid *pt*
-3	invalid *name*
-4	unsupported *name*
-9	unsupported internal code path, consider switching off non-default *iparm* parameters for cluster_sparse_solver
-10	unsupported case when the matrix *A* is distributed among processes with overlap in the preceding calls to cluster_sparse_solver
-12	internal memory error

NOTE Refer to cl_solver_export_f90.f90 for an example using this functionality.

cluster_sparse_solver_set_csr_ptrs

Saves internally-provided pointers to the 3-array CSR data corresponding to the specified name.

Syntax

```
call cluster_sparse_solver_set_csr_ptrs (pt, name, rowptr, colindx, vals, comm, error)
```

Include Files

- mkl_cluster_sparse_solver.f90

Description

This routine internally saves the input pointers, *rowptr*, *colindx*, and *vals*, of the 3-array CSR data, which correspond to the provided *name*. It is assumed that the exported data will be distributed in the same way as the matrix *A* (as defined by *iparm*(40)) used in cluster_sparse_solver.

The saved pointers can then be used for exporting corresponding data by means of cluster_sparse_solver_export.

NOTE
Only call this routine after the factorization phase (*phase*=22) of the cluster_sparse_solver has been called. Neither *pt*, nor *iparm* should be changed after the preceding call to cluster_sparse_solver.

Input Parameters

pt

`INTEGER*8` for 64-bit architectures

Array with size of 64.

Handle to internal data structure used in the prior calls to `cluster_sparse_solver`.

Caution
Do not modify *pt* after the calls to `cluster_sparse_solver`.

name

`INTEGER`

Specifies for which CSR data the pointers are provided.

`SPARSE_PTLUQT_L`	Factor *L* from *P*A*Q=L*U*.
`SPARSE_PTLUQT_U`	Factor *U* from *P*A*Q=L*U*.
`SPARSE_DPTLUQT_L`	Factor *L* from *P* $(D^{-1}A)$*Q=L*U*.
`SPARSE_DPTLUQT_U`	Factor *U* from *P* $(D^{-1}A)$*Q=L*U*.

rowptr

`INTEGER`

Array of length at least (*local_nrows*+1) where *local_nrows* is the local number of rows, which can be obtained by calling `cluster_sparse_solver_get_csr_size`. This array contains row indices, such that *rowptr[i]* - *indexing* is the first index of row *i* in the array's *vals* and *colindx*. Here, the value of *indexing* is 0 for zero-based indexing and 1 for one-based indexing, and must be the same as it was for the matrix *A* used in the preceding calls to `cluster_sparse_solver` (also stored in *iparm(35)*).

Refer to *pointerB* array description in CSR Format for more details.

colindx

`INTEGER`

Array of length at least *rowptr[local_nrows]* – *rowptr[0]*. Indexing (zero- or one-based) must be the same as for *rowptr*. For one-based indexing, the array contains the column indices plus one for each non-zero element of the matrix which corresponds to the *name*. For zero-based indexing, the array contains the column indices for each non-zero element of the matrix.

vals

Array containing non-zero elements of the matrix which corresponds to the *name*. Its length is equal to length of the *colindx* array. Refer to values array description in CSR Format for more details.

It is interpreted internally as one of the following depending on `mtype` (type of the matrix *A*) and *iparm(28)* (precision) specified in the preceding call to `cluster_sparse_solver`.

`DOUBLE PRECISION`	For real types of matrices (`mtype`=1, 2, -2, and 11) and for double precision (*iparm(28)* = 0).

	REAL	For real types of matrices (mtype=1, 2, -2, and 11) and for single precision (*iparm(28)* = 1).
	DOUBLE COMPLEX	For complex types of matrices (mtype=3, 6, 13, 14, and -4) and for double precision (*iparm(28)* = 0).
	COMPLEX	For complex types of matrices (mtype=3, 6, 13, 14, and -4) and for single precision (*iparm(28)* = 1).

comm INTEGER*4

MPI communicator. The solver uses the Fortran MPI communicator internally.

Output Parameters

error INTEGER

The error indicator:

error	**Information**
0	no error
-1	*pt* is a null pointer
-2	invalid *pt*
-3	invalid *name*
-4	unsupported *name*
-9	unsupported internal code path, consider switching off non-default *iparm* parameters for cluster_sparse_solver
-12	internal memory error

NOTE Refer to cl_solver_export_f90.f90 for an example using this functionality.

cluster_sparse_solver_set_ptr

Internally saves a provided pointer to the data corresponding to the specified name.

Syntax

```
call cluster_sparse_solver_set_ptr (pt, name, ptr, comm, error)
```

Include Files

- mkl_cluster_sparse_solver.f90

Description

This routine internally saves the input pointer, *ptr*, of the data which correspond to the provided *name*. The saved pointer can then be used for exporting corresponding data by means of cluster_sparse_solver_export.

NOTE
Only call this routine after the factorization phase (*phase*=22) of the `cluster_sparse_solver` has been called. Neither *pt*, nor *iparm* should be changed after the preceding call to `cluster_sparse_solver`.

Input Parameters

pt

`INTEGER*8` for 64-bit architectures

Array with size of 64.

Handle to internal data structure used in the prior calls to `cluster_sparse_solver`.

Caution
Do not modify *pt* after the calls to `cluster_sparse_solver`.

name

`INTEGER`

Specifies the data for which the pointer is computed.

`SPARSE_PTLUQT_P`	Permutation *P* from $P*A*Q=L*U$.
`SPARSE_PTLUQT_Q`	Permutation *Q* from $P*A*Q=L*U$.
`SPARSE_DPTLUQT_P`	Permutation *P* from $P*(D^{-1}A)*Q=L*U$.
`SPARSE_DPTLUQT_Q`	Permutation *Q* from $P*(D^{-1}A)*Q=L*U$.
`SPARSE_DPTLUQT_D`	Scaling (diagonal) *D* from $P*(D^{-1}A)*Q=L*U$.

vals

Array containing elements of the vector representation for the data which corresponds to the *name*. Its length should be at least *local_nrows*, where *local_nrows* is the local number of rows in a corresponding matrix (obtained from `cluster_sparse_solver_get_csr_size`, for example).

For permutations *P* and *Q*, it is interpreted as `INTEGER`.

For scaling *D*, it is interpreted as one of the following depending on `mtype` (type of the matrix *A*) and *iparm(28)* (precision) specified in the preceding call to `cluster_sparse_solver`.

`DOUBLE PRECISION`	For real types of matrices (`mtype`=1, 2, -2, and 11) and for double precision (*iparm(28)* = 0).
`REAL`	For real types of matrices (`mtype`=1, 2, -2, and 11) and for single precision (*iparm(28)* = 1).
`DOUBLE COMPLEX`	For complex types of matrices (`mtype`=3, 6, 13, 14, and -4) and for double precision (*iparm(28)* = 0).
`COMPLEX`	For complex types of matrices (`mtype`=3, 6, 13, 14, and -4) and for single precision (*iparm(28)* = 1).

comm

`INTEGER*4`

MPI communicator. The solver uses the Fortran MPI communicator internally.

Output Parameters

error INTEGER

The error indicator:

error	Information
0	no error
-1	*pt* is a null pointer
-2	invalid *pt*
-3	invalid *name*
-4	unsupported *name*
-9	unsupported internal code path, consider switching off non-default *iparm* parameters for cluster_sparse_solver
-12	internal memory error

NOTE Refer to cl_solver_export_f90.f90 for an example using this functionality.

cluster_sparse_solver_export

Computes data corresponding to the specified decomposition (defined by export operation) and fills the pointers provided by calls to cluster_sparse_solver_set_ptr *and/or* cluster_sparse_solver_set_csr_ptrs.

Syntax

```
call cluster_sparse_solver_export (pt, operation, comm, error)
```

Include Files

- mkl_cluster_sparse_solver.f90

Description

This routine computes the data for the pointers of the (distributed) data to be exported (as defined the specified *operation*). It is assumed that the exported data will be distributed in the same way as the matrix *A* (as defined by *iparm(40)*) used in cluster_sparse_solver.

NOTE
Only call this routine after the factorization phase (*phase*=22) of the cluster_sparse_solver has been called. Neither *pt*, nor *iparm* should be changed after the preceding call to cluster_sparse_solver.

NOTE
Only call this routine after all pointers to the data required for the specified operation have been provided by means of calling `cluster_sparse_solver_set_ptr` and/or `cluster_sparse_solver_set_csr_ptrs`.

Input Parameters

pt

`INTEGER*8` for 64-bit architectures

Array with size of 64.

Handle to internal data structure used in the prior calls to `cluster_sparse_solver`.

Caution
Do not modify *pt* after the calls to `cluster_sparse_solver`.

operation

`INTEGER`

Specifies a particular operation which defines what data are exported

`SPARSE_PTLUQT`	Exporting data from decomposition $P*A*Q=L*U$.
`SPARSE_DPTLUQT`	Exporting data from decomposition from $P*(D^{-1}A)*Q=L*U$.

NOTE
Currently, for *operation*=`SPARSE_DPTLUQT` a real (complex) unit vector is provided for the scaling matrix *D*. Do not turn on scaling(*iparm(11)*>0) or matching(*iparm(13)*>0) in the *iparm* during the call to `cluster_sparse_solver` for this value of *operation*.

comm

`INTEGER*4`

MPI communicator. The solver uses the Fortran MPI communicator internally.

Output Parameters

error

`INTEGER`

The error indicator:

error	**Information**
`0`	no error
`-1`	*pt* is a null pointer
`-2`	invalid *pt*
`-5`	invalid *operation*

error	Information
-6	pointers to some of the data required for the specified *operation* were not provided prior to calling cluster_sparse_solver_export
-9	unsupported internal code path, consider switching off non-default *iparm* parameters for cluster_sparse_solver
-10	unsupported case when the matrix *A* is distributed among processes with overlap in the preceding calls to cluster_sparse_solver
-12	internal memory error

NOTE Refer to cl_solver_export_f90.f90 for an example using this functionality.

cluster_sparse_solver iparm Parameter

The following table describes all individual components of the Parallel Direct Sparse Solver for Clusters Interface *iparm* parameter. Components which are not used must be initialized with 0. Default values are denoted with an asterisk (*).

Component	Description	
iparm(1) input	Use default values.	
	0	*iparm*(2) - *iparm*(64) are filled with default values.
	!=0	You must supply all values in components *iparm*(2) - *iparm*(64).
iparm(2) input	Fill-in reducing ordering for the input matrix.	
	2*	The nested dissection algorithm from the METIS package [Karypis98].
	3	The parallel version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Phase 1 takes significant time.
	10	The MPI version of the nested dissection and symbolic factorization algorithms for the matrix in distributed assembled matrix input format (iparm(40) > 0). The input matrix for the reordering must be distributed among different MPI processes without any intersection and all MPI ranks must have at least one row of the input matrix. Use iparm(41) and iparm(42) to set the bounds of the domain. During all of Phase 1, the entire matrix is not gathered on any one process, which can decrease computation time (especially when Phase 1 takes significant time) and decrease memory usage for each MPI process on the cluster. **NOTE** Distributed reordering does not work if any of matching(iparm(13)=1)/scaling(iparm(11)=1)/BSR format(iparm(37)>1)/Schur complement matrix computation control(iparm(36)>0)/Partial solve(iparm(31) > 0) is turned on, or if the distributed input matrix has overlapping distribution of rows across MPI processes.

Component	Description
	NOTE If you set *iparm*(2) = 10, *comm* = -1 (MPI communicator), and if there is one MPI process, optimization and full parallelization with the OpenMP version of the nested dissection and symbolic factorization algorithms proceeds. This can decrease computation time on multi-core computers. In this case, set *iparm*(41) = 1 and *iparm*(42) = *n* for one-based indexing, or to 0 and *n* – 1, respectively, for zero-based indexing.
iparm(3)	Reserved. Set to zero.
iparm(4)	Reserved. Set to zero.
iparm(5) input	User permutation. This parameter controls whether user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms. Another use of this parameter is to control obtaining the fill-in reducing permutation vector calculated during the reordering stage of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. This option is useful for testing reordering algorithms, adapting the code to special applications problems (for instance, to move zero diagonal elements to the end of $P*A*P^T$), or for using the permutation vector more than once for matrices with identical sparsity structures. For definition of the permutation, see the description of the *perm* parameter. **Caution** You can only set one of *iparm*(5), *iparm*(31), and *iparm*(36), so be sure that the *iparm*(31) (partial solution) and the *iparm*(36) (Schur complement) parameters are 0 if you set *iparm*(5).
	0 — User permutation in the *perm* array is ignored. 1 — Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the user supplied fill-in reducing permutation from the*perm* array. *iparm*(2) is ignored. 2 — Intel® oneAPI Math Kernel Library (oneMKL) PARDISO returns the permutation vector computed at phase 1 in the*perm* array.
iparm(6) input	Write solution on *x*. **NOTE** The array *x* is always used.
	0* — The array *x* contains the solution; right-hand side vector *b* is kept unchanged. 1 — The solver stores the solution on the right-hand side *b*.
iparm(7) output	Number of iterative refinement steps performed. Reports the number of iterative refinement steps that were actually performed during the solve step.
iparm(8) input	Iterative refinement step. On entry to the solve and iterative refinement step, *iparm*(8) must be set to the maximum number of iterative refinement steps that the solver performs.

Component	Description	
	0*	The solver automatically performs two steps of iterative refinement when perturbed pivots are obtained during the numerical factorization.
	>0	Maximum number of iterative refinement steps that the solver performs. The solver performs not more than the absolute value of *iparm*(8) steps of iterative refinement. The solver might stop the process before the maximum number of steps if • a satisfactory level of accuracy of the solution in terms of backward error is achieved, • or if it determines that the required accuracy cannot be reached. In this case Parallel Direct Sparse Solver for Clusters Interface returns -4 in the *error* parameter. The number of executed iterations is reported in *iparm*(7).
	<0	Same as above, but the accumulation of the residuum uses extended precision real and complex data types. Perturbed pivots result in iterative refinement (independent of *iparm*(8)=0) and the number of executed iterations is reported in *iparm*(7).
iparm(9)	Reserved. Set to zero.	
iparm(10) input	Pivoting perturbation. This parameter instructs Parallel Direct Sparse Solver for Clusters Interface how to handle small pivots or zero pivots for nonsymmetric matrices (*mtype* =11 or *mtype* =13) and symmetric matrices (*mtype* =-2, *mtype* =-4, or *mtype* =6). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04]. Small pivots are perturbed with eps = $10^{-iparm(10)}$. The magnitude of the potential pivot is tested against a constant threshold of alpha = eps*$\|\|A2\|\|_{inf}$, where eps = $10^{(-iparm(10))}$, $A2 = P*P_{MPS}*D_r*A*D_c*P$, and $\|\|A2\|\|_{inf}$ is the infinity norm of the scaled and permuted matrix *A*. Any tiny pivots encountered during elimination are set to the sign (l_{II})*eps*$\|\|A2\|\|_{inf}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with eps = $10^{(-iparm(10))}$.	
	13*	The default value for nonsymmetric matrices(*mtype* =11, *mtype*=13), eps = 10^{-13}.
	8*	The default value for symmetric indefinite matrices (*mtype* =-2, *mtype*=-4, *mtype*=6), eps = 10^{-8}.
iparm(11) input	Scaling vectors. Parallel Direct Sparse Solver for Clusters Interface uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale. Use *iparm*(11) = 1 (scaling) and *iparm*(13) = 1 (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point problems. Note that in the analysis phase (*phase*=11) you must provide the numerical values of the matrix *A* in array *a* in case of scaling and symmetric weighted matching.	
	0*	Disable scaling. Default for symmetric indefinite matrices.

Component	Description
	1* Enable scaling. Default for nonsymmetric matrices. Scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied to nonsymmetric matrices (*mtype* = 11, *mtype* = 13). The scaling can also be used for symmetric indefinite matrices (*mtype* = -2, *mtype* = -4, *mtype* = 6) when the symmetric weighted matchings are applied (*iparm*(13) = 1). Note that in the analysis phase (*phase*=11) you must provide the numerical values of the matrix *A* in case of scaling.
iparm(12)	Solve with transposed or conjugate transposed matrix *A*. **NOTE** For real matrices, the terms *transposed* and *conjugate transposed* are equivalent. 0* Solve a linear system $AX = B$. 1 Solve a conjugate transposed system $A^HX = B$ based on the factorization of the matrix *A*. 2 Solve a transposed system $A^TX = B$ based on the factorization of the matrix *A*.
iparm(13) input	Improved accuracy using (non-) symmetric weighted matching. Parallel Direct Sparse Solver for Clusters Interface can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to the factorization methods and complements the alternative of using more complete pivoting techniques during the numerical factorization. 0* Disable matching. Default for symmetric indefinite matrices. 1* Enable matching. Default for nonsymmetric matrices. Maximum weighted matching algorithm to permute large elements close to the diagonal. It is recommended to use *iparm*(11) = 1 (scaling) and *iparm*(13) = 1 (matching) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems. Note that in the analysis phase (*phase*=11) you must provide the numerical values of the matrix *A* in case of symmetric weighted matching.
iparm(14) output	Number of perturbed pivots. After factorization, contains the number of perturbed pivots for the matrix types: 1, 3, 11, 13, -2, -4 and 6.
iparm(15) output	Peak memory on symbolic factorization. The total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase. This value is only computed in phase 1.
iparm(16) output	Permanent memory on symbolic factorization. Permanent memory from the analysis and symbolic factorization phase in kilobytes that the solver needs in the factorization and solve phases.

Component	Description	
	This value is only computed in phase 1.	
iparm(17) output	Size of factors/Peak memory on numerical factorization and solution. This parameter provides the size in kilobytes of the total memory consumed by in-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO for internal floating point arrays. This parameter is computed in phase 1. See *iparm*(63) for the OOC mode. The total peak memory consumed by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO is max(*iparm*(15), *iparm*(16)+*iparm*(17))	
iparm(18) input/output	Report the number of non-zero elements in the factors.	
	<0	Enable reporting if *iparm*(18) < 0 on entry. The default value is -1.
	>=0	Disable reporting.
iparm(19) - *iparm*(20)	Reserved. Set to zero.	
iparm(21) input	Pivoting for symmetric indefinite matrices.	
	0	Apply 1x1 diagonal pivoting during the factorization process.
	1*	Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of *mtype*=-2, *mtype*=-4, or *mtype*=6.
iparm(22) output	Inertia: number of positive eigenvalues. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO reports the number of positive eigenvalues for symmetric indefinite matrices.	
iparm(23) output	Inertia: number of negative eigenvalues. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO reports the number of negative eigenvalues for symmetric indefinite matrices.	
iparm(24) - *iparm*(26)	Reserved. Set to zero.	
iparm(27) input	Matrix checker.	
	0*	Do not check the sparse matrix representation for errors.
	1	Check integer arrays *ia* and *ja*. In particular, check whether the column indices are sorted in increasing order within each row.
iparm(28) input	Single or double precision Parallel Direct Sparse Solver for Clusters Interface. See *iparm*(8) for information on controlling the precision of the refinement steps.	
	0*	Input arrays (*a*, *x* and *b*) and all internal arrays must be presented in double precision.
	1	Input arrays (*a*, *x* and *b*) must be presented in single precision. In this case all internal computations are performed in single precision.
iparm(29)	Reserved. Set to zero.	
iparm(30) output	Number of zero or negative pivots.	

Component	Description
	If Intel® oneAPI Math Kernel Library (oneMKL) PARDISO detects zero or negative pivot for*mtype*=2 or *mtype*=4 matrix types, the factorization is stopped. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO returns immediately with an*error* = -4, and *iparm*(30) reports the number of the equation where the zero or negative pivot is detected. Note: The returned value can be different for the parallel and sequential version in case of several zero/negative pivots.
iparm(31) input	Partial solve and computing selected components of the solution vectors. This parameter controls the solve step of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. It can be used if only a few components of the solution vectors are needed or if you want to reduce the computation cost at the solve step by utilizing the sparsity of the right-hand sides. To use this option the input permutation vector define*perm* so that when *perm*(*i*) = 1 it means that either the *i*-th component in the right-hand sides is nonzero, or the *i*-th component in the solution vectors is computed, or both, depending on the value of *iparm*(31). The permutation vector *perm*must be present in all phases of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO software. At the reordering step, the software overwrites the input vector*perm* by a permutation vector used by the software at the factorization and solver step. If *m* is the number of components such that *perm*(*i*) = 1, then the last *m* components of the output vector *perm* are a set of the indices *i* satisfying the condition *perm*(*i*) = 1 on input. **NOTE** Turning on this option often increases the time used by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO for factorization and reordering steps, but it can reduce the time required for the solver step. **Important** Set the parameters *iparm*(8) (iterative refinement steps), *iparm*(4) (preconditioned CGS), *iparm*(5) (user permutation), and *iparm*(36) (Schur complement) to 0 as well.

0*	Disables this option.
1	it is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector *perm* is defined so that *perm*(*i*) = 1 means that the (*i*)-th component in the right-hand sides is nonzero. In this case Intel® oneAPI Math Kernel Library (oneMKL) PARDISO only uses the non-zero components of the right-hand side vectors and computes only corresponding components in the solution vectors. That means the*i*-th component in the solution vectors is only computed if *perm*(*i*) = 1.
2	It is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector *perm* is defined so that *perm*(*i*) = 1 means that the *i*-th component in the right-hand sides is nonzero. Unlike for *iparm*(31)=1, all components of the solution vector are computed for this setting and all components of the right-hand sides are used. Because all components are used, for *iparm*(31)=2 you must set the *i*-th component of the right-hand sides to zero explicitly if *perm*(*i*) is not equal to 1.

Component	Description	
	3	Selected components of the solution vectors are computed. The *perm* array is not related to the right-hand sides and it only indicates which components of the solution vectors should be computed. In this case *perm*(*i*) = 1 means that the *i*-th component in the solution vectors is computed.
iparm(31) - *iparm*(33)	Reserved. Set to zero.	
iparm(35) input	One- or zero-based indexing of columns and rows.	
	0*	One-based indexing: columns and rows indexing in arrays *ia*, *ja*, and *perm* starts from 1 (Fortran-style indexing).
	1	Zero-based indexing: columns and rows indexing in arrays *ia*, *ja*, and *perm* starts from 0 (C-style indexing).
iparm(36) input	Schur complement matrix computation control. To calculate this matrix, you must set the input permutation vector *perm* to a set of indexes such that when *perm*(*i*) = 1, the *i*-th element of the initial matrix is an element of the Schur matrix. **Caution** You can only set one of *iparm*(5), *iparm*(31), and *iparm*(36), so be sure that the *iparm*(5) (user permutation) and the *iparm*(31) (partial solution) parameters are 0 if you set *iparm*(36).	
	0*	Do not compute Schur complement.
	1	Compute Schur complement matrix as part of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO factorization step and return it in the solution vector. **NOTE** This option only computes the Schur complement matrix, and does not calculate factorization arrays.
	2	Compute Schur complement matrix as part of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO factorization step and return it in the solution vector. Since this option calculates factorization arrays you can use it to launch partial or full solution of the entire problem after the factorization step.
iparm(37) input	Format for matrix storage.	
	0*	Use CSR format (see Three Array Variation of BSR Format) for matrix storage.
	1	Use CSR format (see Three Array Variation of BSR Format) for matrix storage.
	< 0	Convert supplied matrix to variable BSR (VBSR) format (see Sparse Data Storage) for matrix storage. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO analyzes the matrix provided in CSR3 format and converts it to an internal VBSR format. Set*iparm*(37) = $-t$, $0 < t \leq 100$.
iparm(38) - *iparm*(39)	Reserved. Set to zero.	
iparm(40) input	Matrix input format.	

Component	Description
	NOTE Performance of the reordering step of the Parallel Direct Sparse Solver for Clusters Interface is slightly better for assembled format (CSR, *iparm*(40) = 0) than for distributed format (DCSR, *iparm*(40) > 0) for the same matrices, so if the matrix is assembled on one node do not distribute it before calling cluster_sparse_solver.
	0* — Provide the matrix in usual centralized input format: the master MPI process stores all data from matrix *A*, with rank=0.
	1 — Provide the matrix in distributed assembled matrix input format. In this case, each MPI process stores only a part (or domain) of the matrix *A* data. Set the bounds of the domain using *iparm*(41) and *iparm*(42). The solution vector is placed on the master process.
	2 — Provide the matrix in distributed assembled matrix input format. In this case, each MPI process stores only a part (or domain) of the matrix *A* data. Set the bounds of the domain using *iparm*(41) and *iparm*(42). The solution vector, *A*, and RHS elements are distributed between processes in same manner.
	3 — Provide the matrix in distributed assembled matrix input format. In this case, each MPI process stores only a part (or domain) of the matrix *A* data. Set the bounds of the domain using *iparm*(41) and *iparm*(42). The *A* and RHS elements are distributed between processes in same manner and the solution vector is the same on each process
iparm(41) input	Beginning of input domain. The number of the matrix *A* row, RHS element, and, for *iparm*(40)=2, solution vector that begins the input domain belonging to this MPI process. Only applicable to the distributed assembled matrix input format (*iparm*(40)> 0). See Sparse Matrix Storage Formats for more details.
iparm(42) input	End of input domain. The number of the matrix *A* row, RHS element, and, for *iparm*(40)=2, solution vector that ends the input domain belonging to this MPI process. Only applicable to the distributed assembled matrix input format (*iparm*(40)> 0). See Sparse Matrix Storage Formats for more details.
iparm(43) - *iparm*(59) input	Reserved. Set to zero.
iparm(60) input	cluster_sparse_solver mode. *iparm*(60) switches between in-core (IC) and out-of-core (OOC) of cluster_sparse_solver. OOC can solve very large problems by holding the matrix factors in files on the disk, which requires a reduced amount of main memory compared to IC. Unless you are operating in sequential mode, you can switch between IC and OOC modes after the reordering phase. However, you can get better cluster_sparse_solver performance by setting *iparm*(60) before the reordering phase. The amount of memory used in OOC mode depends on the number of OpenMP threads.

Component	Description
	Warning Do not increase the number of OpenMP threads used for cluster_sparse_solver between the first call and the factorization or solution phase. Because the minimum amount of memory required for out-of-core execution depends on the number of OpenMP threads, increasing it after the initial call can cause incorrect results.
	0* IC mode.
	1 IC mode is used if the total amount of RAM (in megabytes) needed for storing the matrix factors is less than sum of two values of the environment variables: `MKL_PARDISO_OOC_MAX_CORE_SIZE` (default value 2000 MB) and `MKL_PARDISO_OOC_MAX_SWAP_SIZE` (default value 0 MB); otherwise OOC mode is used. In this case amount of RAM used by OOC mode cannot exceed the value of `MKL_PARDISO_OOC_MAX_CORE_SIZE`. If the total peak memory needed for storing the local arrays is more than `MKL_PARDISO_OOC_MAX_CORE_SIZE`, increase `MKL_PARDISO_OOC_MAX_CORE_SIZE` if possible. **NOTE** Conditional numerical reproducibility (CNR) is not supported for this mode.
	2 OOC mode. The OOC mode can solve very large problems by holding the matrix factors in files on the disk. Hence the amount of RAM required by OOC mode is significantly reduced compared to IC mode. If the total peak memory needed for storing the local arrays is more than `MKL_PARDISO_OOC_MAX_CORE_SIZE`, increase `MKL_PARDISO_OOC_MAX_CORE_SIZE` if possible. To obtain better cluster_sparse_solver performance, during the numerical factorization phase you can provide the maximum number of right-hand sides, which can be used further during the solving phase. **NOTE** To use OOC mode, you must disable *iparm*(11) (scaling) and *iparm*(13) = 1 (matching).
iparm(61) - *iparm*(62) input	Reserved. Set to zero.
iparm(63) output	Size of the minimum OOC memory for numerical factorization and solution. This parameter provides the size in kilobytes of the minimum memory required by OOC Intel® oneAPI Math Kernel Library (oneMKL) PARDISO for internal floating point arrays. This parameter is computed in phase 1. Total peak memory consumption of OOC Intel® oneAPI Math Kernel Library (oneMKL) PARDISO can be estimated as max(*iparm*(15), *iparm*(16) + *iparm*(63)).
iparm(64) input	Reserved. Set to zero.

NOTE
Generally in sparse matrices, components which are equal to zero can be considered non-zero if necessary. For example, in order to make a matrix structurally symmetric, elements which are zero can be considered non-zero. See Sparse Matrix Storage Formats for an example.

Direct Sparse Solver (DSS) Interface Routines

Intel® oneAPI Math Kernel Library (oneMKL) supports the DSS interface, an alternative to the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO interface for the direct sparse solver. The DSS interface implements a group of user-callable routines that are used in the step-by-step solving process and utilizes the general scheme described inAppendix A Linear Solvers Basics for solving sparse systems of linear equations. This interface also includes one routine for gathering statistics related to the solving process and an auxiliary routine for passing character strings from Fortran routines to C routines.

The DSS interface also supports the out-of-core (OOC) mode.

Table "DSS Interface Routines" lists the names of the routines and describes their general use.

DSS Interface Routines

Routine	Description
dss_create	Initializes the solver and creates the basic data structures necessary for the solver. This routine must be called before any other DSS routine.
dss_define_structure	Informs the solver of the locations of the non-zero elements of the matrix.
dss_reorder	Based on the non-zero structure of the matrix, computes a permutation vector to reduce fill-in during the factoring process.
dss_factor_real, dss_factor_complex	Computes the LU, LDL^T or LL^T factorization of a real or complex matrix.
dss_solve_real, dss_solve_complex	Computes the solution vector for a system of equations based on the factorization computed in the previous phase.
dss_delete	Deletes all data structures created during the solving process.
dss_statistics	Returns statistics about various phases of the solving process.
mkl_cvt_to_null_terminated_str	Passes character strings from Fortran routines to C routines.

To find a single solution vector for a single system of equations with a single right-hand side, invoke the Intel® oneAPI Math Kernel Library (oneMKL) DSS interface routines in this order:

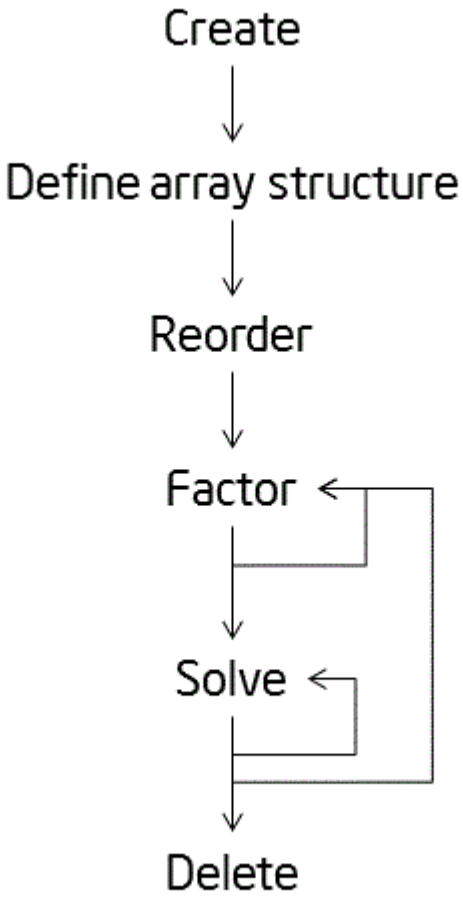
1. dss_create
2. dss_define_structure
3. dss_reorder
4. dss_factor_real, dss_factor_complex

5. dss_solve_real, dss_solve_complex
6. dss_delete

However, in certain applications it is necessary to produce solution vectors for multiple right-hand sides for a given factorization and/or factor several matrices with the same non-zero structure. Consequently, it is sometimes necessary to invoke the Intel® oneAPI Math Kernel Library (oneMKL) sparse routines in an order other than that listed, which is possible using the DSS interface. The solving process is conceptually divided into six phases.Figure "Typical order for invoking DSS interface routines" indicates the typical order in which the DSS interface routines can be invoked.

__border__top

Typical order for invoking DSS interface routines



See the code examples that use the DSS interface routines to solve systems of linear equations in the Intel® oneAPI Math Kernel Library (oneMKL) installation directory (`dss_*.f`).

- `examples/solverf/source`

DSS Interface Description

Each DSS routine reads from or writes to a data object called a *handle*. Refer to Memory Allocation and Handles to determine the correct method for declaring a handle argument for each language. For simplicity, the descriptions in DSS routines refer to the data type as `MKL_DSS_HANDLE`.

Routine Options

The DSS routines have an integer argument (referred below to as *opt*) for passing various options to the routines. The permissible values for *opt* should be specified using only the symbol constants defined in the language-specific header files (see Implementation Details). The routines accept options for setting the message and termination levels as described in Table "Symbolic Names for the Message and Termination Levels Options". Additionally, each routine accepts the option `MKL_DSS_DEFAULTS` that sets the default values (as documented) for *opt* to the routine.

Symbolic Names for the Message and Termination Levels Options

Message Level	Termination Level
MKL_DSS_MSG_LVL_SUCCESS	MKL_DSS_TERM_LVL_SUCCESS
MKL_DSS_MSG_LVL_INFO	MKL_DSS_TERM_LVL_INFO
MKL_DSS_MSG_LVL_WARNING	MKL_DSS_TERM_LVL_WARNING
MKL_DSS_MSG_LVL_ERROR	MKL_DSS_TERM_LVL_ERROR
MKL_DSS_MSG_LVL_FATAL	MKL_DSS_TERM_LVL_FATAL

The settings for message and termination levels can be set on any call to a DSS routine. However, once set to a particular level, they remain at that level until they are changed in another call to a DSS routine.

You can specify both message and termination level for a DSS routine by adding the options together. For example, to set the message level to `debug` and the termination level to `error` for all the DSS routines, use the following call:

```
CALL dss_create( handle, MKL_DSS_MSG_LVL_INFO + MKL_DSS_TERM_LVL_ERROR)
```

User Data Arrays

Many of the DSS routines take arrays of user data as input. For example, user arrays are passed to the routine `dss_define_structure` to describe the location of the non-zero entries in the matrix.

Caution
Do not modify the contents of these arrays after they are passed to one of the solver routines.

DSS Implementation Details

To promote portability across platforms and ease of use across different languages, use the `mkl_dss.f90` header file.

The header file defines symbolic constants for returned error values, function options, certain defined data types, and function prototypes.

NOTE
Constants for options, returned error values, and message severities must be referred only by the symbolic names that are defined in these header files. Use of the Intel® oneAPI Math Kernel Library (oneMKL) DSS software without including one of the above header files is not supported.

Memory Allocation and Handles

You do not need to allocate any temporary working storage in order to use the Intel® oneAPI Math Kernel Library (oneMKL) DSS routines, because the solver itself allocates any required storage. To enable multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a*handle* data object.

Each of the Intel® oneAPI Math Kernel Library (oneMKL) DSS routines creates, uses, or deletes a handle. Consequently, any program calling an Intel® oneAPI Math Kernel Library (oneMKL) DSS routine must be able to allocate storage for a handle. The exact syntax for allocating storage for a handle varies from language to language. To standardize the handle declarations, the language-specific header files declare constants and defined data types that must be used when declaring a handle object in your code.

```
INCLUDE "mkl_dss.f90"
TYPE(MKL_DSS_HANDLE) handle
```

In addition to the definition for the correct declaration of a handle, the include file also defines the following:

- function prototypes for languages that support prototypes
- symbolic constants that are used for the returned error values
- user options for the solver routines
- constants indicating message severity.

DSS Routines

dss_create

Initializes the solver.

Syntax

`call dss_create(handle, opt)`

Include Files

- `mkl.fi`, `mkl_dss.f90`

Description

The `dss_create` routine initializes the solver. After the call to `dss_create`, all subsequent invocations of the Intel® oneAPI Math Kernel Library (oneMKL) DSS routines must use the value of the handle returned by`dss_create`.

> **WARNING**
> Do not write the value of handle directly.

The default value of the parameter *opt* is

`MKL_DSS_MSG_LVL_WARNING` + `MKL_DSS_TERM_LVL_ERROR`.

By default, the DSS routines use double precision for solving systems of linear equations. The precision used by the DSS routines can be set to single mode by adding the following value to the *opt* parameter:

`MKL_DSS_SINGLE_PRECISION`.

Input data and internal arrays are required to have single precision.

By default, the DSS routines use Fortran style (one-based) indexing for input arrays of integer types (the first value is referenced as array element 1). To set indexing to C style (the first value is referenced as array element 0), add the following value to the *opt* parameter:

MKL_DSS_ZERO_BASED_INDEXING.

The *opt* parameter can also control number of refinement steps used on the solution stage by specifying the two following values:

MKL_DSS_REFINEMENT_OFF - maximum number of refinement steps is set to zero;
MKL_DSS_REFINEMENT_ON (default value) - maximum number of refinement steps is set to 2.

By default, DSS uses in-core computations. To launch the out-of-core version of DSS (OOC DSS) you can add to this parameter one of two possible values: MKL_DSS_OOC_STRONG and MKL_DSS_OOC_VARIABLE.

MKL_DSS_OOC_STRONG - OOC DSS is used.

MKL_DSS_OOC_VARIABLE - if the memory needed for the matrix factors is less than the value of the environment variable MKL_PARDISO_OOC_MAX_CORE_SIZE, then the OOC DSS uses the in-core kernels of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO, otherwise it uses the OOC computations.

The variable MKL_PARDISO_OOC_MAX_CORE_SIZE defines the maximum size of RAM allowed for storing work arrays associated with the matrix factors. It is ignored if MKL_DSS_OOC_STRONG is set. The default value of MKL_PARDISO_OOC_MAX_CORE_SIZE is 2000 MB. This value and default path and file name for storing temporary data can be changed using the configuration file pardiso_ooc.cfg or command line (See more details in the description of the pardiso routine).

WARNING
Other than message and termination level options, do not change the OOC DSS settings after they are specified in the routine dss_create.

Input Parameters

opt

INTEGER, INTENT(IN)

Parameter to pass the DSS options. The default value is MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR.

Output Parameters

handle

TYPE (MKL_DSS_HANDLE), INTENT(OUT)

Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).

Return Values

MKL_DSS_SUCCESS

MKL_DSS_INVALID_OPTION

MKL_DSS_OUT_OF_MEMORY

MKL_DSS_MSG_LVL_ERR

MKL_DSS_TERM_LVL_ERR

dss_define_structure

Communicates locations of non-zero elements in the matrix to the solver.

Syntax

```
call dss_define_structure(handle, opt, rowIndex, nRows, nCols, columns, nNonZeros);
```

Include Files

- mkl.fi, mkl_dss.f90

Description

The routine dss_define_structure communicates the locations of the *nNonZeros* number of non-zero elements in a matrix of *nRows * nCols* size to the solver.

> **NOTE**
> The Intel® oneAPI Math Kernel Library (oneMKL) DSS software operates only on square matrices, so*nRows* must be equal to *nCols*.

To communicate the locations of non-zero elements in the matrix, do the following:

1. Define the general non-zero structure of the matrix by specifying the value for the options argument *opt*. You can set the following values for real matrices:
   - MKL_DSS_SYMMETRIC_STRUCTURE
   - MKL_DSS_SYMMETRIC
   - MKL_DSS_NON_SYMMETRIC

   and for complex matrices:
   - MKL_DSS_SYMMETRIC_STRUCTURE_COMPLEX
   - MKL_DSS_SYMMETRIC_COMPLEX
   - MKL_DSS_NON_SYMMETRIC_COMPLEX

   The information about the matrix type must be defined in dss_define_structure.
2. Provide the actual locations of the non-zeros by means of the arrays *rowIndex* and *columns* (see Sparse Matrix Storage Format).

> **NOTE** No diagonal element can be omitted from the values array. If there is a zero value on the diagonal, for example, that element nonetheless must be explicitly represented.

Input Parameters

opt — INTEGER, INTENT(IN)

Parameter to pass the DSS options. The default value for the matrix structure is MKL_DSS_SYMMETRIC.

rowIndex — INTEGER, INTENT(IN)

Array of size *nRows*+1. Defines the location of non-zero entries in the matrix.

nRows — INTEGER, INTENT(IN)

Number of rows in the matrix.

nCols — INTEGER, INTENT(IN)

Number of columns in the matrix; must be equal to *nRows*.

columns	INTEGER, INTENT(IN) Array of size *nNonZeros*. Defines the column location of non-zero entries in the matrix.
nNonZeros	INTEGER, INTENT(IN) Number of non-zero elements in the matrix.

Output Parameters

handle	TYPE (MKL_DSS_HANDLE), INTENT(INOUT) Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).

Return Values

MKL_DSS_SUCCESS

MKL_DSS_STATE_ERR

MKL_DSS_INVALID_OPTION

MKL_DSS_STRUCTURE_ERR

MKL_DSS_ROW_ERR

MKL_DSS_COL_ERR

MKL_DSS_NOT_SQUARE

MKL_DSS_TOO_FEW_VALUES

MKL_DSS_TOO_MANY_VALUES

MKL_DSS_OUT_OF_MEMORY

MKL_DSS_MSG_LVL_ERR

MKL_DSS_TERM_LVL_ERR

dss_reorder

Computes or sets a permutation vector that minimizes the fill-in during the factorization phase.

Syntax

```
call dss_reorder(handle, opt, perm)
```

Include Files

- mkl.fi, mkl_dss.f90

Description

If *opt* contains the option MKL_DSS_AUTO_ORDER, then the routine dss_reorder computes a permutation vector that minimizes the fill-in during the factorization phase. For this option, the routine ignores the contents of the *perm* array.

If *opt* contains the option MKL_DSS_METIS_OPENMP_ORDER, then the routine dss_reorder computes permutation vector using the parallel nested dissections algorithm to minimize the fill-in during the factorization phase. This option can be used to decrease the time of dss_reorder call on multi-core computers. For this option, the routine ignores the contents of the *perm* array.

If *opt* contains the option MKL_DSS_MY_ORDER, then you must supply a permutation vector in the array *perm*. In this case, the array *perm* is of length *nRows*, where *nRows* is the number of rows in the matrix as defined by the previous call to dss_define_structure.

If *opt* contains the option MKL_DSS_GET_ORDER, then the permutation vector computed during the dss_reorder call is copied to the array *perm*. In this case you must allocate the array *perm* beforehand. The permutation vector is computed in the same way as if the option MKL_DSS_AUTO_ORDER is set.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Input Parameters

opt

INTEGER, INTENT(IN)

Parameter to pass the DSS options. The default value for the permutation type is MKL_DSS_AUTO_ORDER.

perm

INTEGER, INTENT(IN)

Array of length *nRows*. Contains a user-defined permutation vector (accessed only if *opt* contains MKL_DSS_MY_ORDER or MKL_DSS_GET_ORDER).

Output Parameters

handle

TYPE (MKL_DSS_HANDLE), INTENT(INOUT)

Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).

Return Values

MKL_DSS_SUCCESS

MKL_DSS_STATE_ERR

MKL_DSS_INVALID_OPTION

MKL_DSS_REORDER_ERR

MKL_DSS_REORDER1_ERR

MKL_DSS_I32BIT_ERR

MKL_DSS_FAILURE

MKL_DSS_OUT_OF_MEMORY

MKL_DSS_MSG_LVL_ERR

MKL_DSS_TERM_LVL_ERR

dss_factor_real, dss_factor_complex

Compute factorization of the matrix with previously specified location of non-zero elements.

Syntax

```
call dss_factor_real(handle, opt, rValues)
call dss_factor_complex(handle, opt, cValues)
call dss_factor(handle, opt, Values)
```

Include Files

- mkl.fi, mkl_dss.f90

Description

These routines compute factorization of the matrix whose non-zero locations were previously specified by a call to dss_define_structure and whose non-zero values are given in the array *rValues*, *cValues* or *Values*. Data type These arrays must be of length *nNonZeros* as defined in a previous call to dss_define_structure.

> **NOTE**
> The data type (single or double precision) of *rValues*, *cValues*, *Values* must be in correspondence with precision specified by the parameter *opt* in the routine dss_create.

The *opt* argument can contain one of the following options:

- MKL_DSS_POSITIVE_DEFINITE
- MKL_DSS_INDEFINITE
- MKL_DSS_HERMITIAN_POSITIVE_DEFINITE
- MKL_DSS_HERMITIAN_INDEFINITE

depending on your matrix's type.

> **NOTE**
> This routine supports the Progress Routine feature. See Progress Function for details.

Input Parameters

handle

TYPE (MKL_DSS_HANDLE), INTENT(INOUT)

Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).

opt

INTEGER, INTENT(IN)

Parameter to pass the DSS options. The default value is MKL_DSS_POSITIVE_DEFINITE.

rValues

REAL*8

REAL(KIND=4), INTENT(IN) or

REAL(KIND=8), INTENT(IN)

Array of elements of the matrix *A*. Real data, single or double precision as it is specified by the parameter *opt* in the routine dss_create.

cValues

COMPLEX*16

	`COMPLEX(KIND=4), INTENT(IN)` or `COMPLEX(KIND=8), INTENT(IN)` Array of elements of the matrix *A*. Complex data, single or double precision as it is specified by the parameter *opt* in the routine `dss_create`.
Values	`REAL(KIND=4), INTENT(OUT),` or `REAL(KIND=8), INTENT(OUT),` or `COMPLEX(KIND=4), INTENT(OUT),` or `COMPLEX(KIND=8), INTENT(OUT)` Array of elements of the matrix *A*. Real or complex data, single or double precision as it is specified by the parameter *opt* in the routine `dss_create`.

Return Values

`MKL_DSS_SUCCESS`

`MKL_DSS_STATE_ERR`

`MKL_DSS_INVALID_OPTION`

`MKL_DSS_OPTION_CONFLICT`

`MKL_DSS_VALUES_ERR`

`MKL_DSS_OUT_OF_MEMORY`

`MKL_DSS_ZERO_PIVOT`

`MKL_DSS_FAILURE`

`MKL_DSS_MSG_LVL_ERR`

`MKL_DSS_TERM_LVL_ERR`

`MKL_DSS_OOC_MEM_ERR`

`MKL_DSS_OOC_OC_ERR`

`MKL_DSS_OOC_RW_ERR`

dss_solve_real, dss_solve_complex

Compute the corresponding solution vector and place it in the output array.

Syntax

```
call dss_solve_real(handle, opt, rRhsValues, nRhs, rSolValues)
call dss_solve_complex(handle, opt, cRhsValues, nRhs, cSolValues)
call dss_solve(handle, opt, RhsValues, nRhs, SolValues)
```

Include Files

- `mkl.fi, mkl_dss.f90`

Description

For each right-hand side column vector defined in the arrays *rRhsValues*, *cRhsValues*, or *RhsValues*, these routines compute the corresponding solution vector and place it in the arrays *rSolValues*, *cSolValues*, or *SolValues* respectively.

> **NOTE**
> The data type (single or double precision) of all arrays must be in correspondence with precision specified by the parameter *opt* in the routine dss_create.

The lengths of the right-hand side and solution vectors, *nRows* and *nCols* respectively, must be defined in a previous call to dss_define_structure.

By default, both routines perform the full solution step (it corresponds to *phase* = 33in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO). The parameter*opt* enables you to calculate the final solution step-by-step, calling forward and backward substitutions.

If it is set to MKL_DSS_FORWARD_SOLVE, the forward substitution (corresponding to *phase* = 331in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO) is performed;

if it is set to MKL_DSS_DIAGONAL_SOLVE, the diagonal substitution (corresponding to *phase* = 332in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO) is performed, if possible;

if it is set to MKL_DSS_BACKWARD_SOLVE, the backward substitution (corresponding to *phase* = 333in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO) is performed.

For more details about using these substitutions for different types of matrices, see Separate Forward and Backward Substitutionin the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver description.

This parameter also can control the number of refinement steps that is used on the solution stage: if it is set to MKL_DSS_REFINEMENT_OFF, the maximum number of refinement steps equal to zero, and if it is set to MKL_DSS_REFINEMENT_ON (default value), the maximum number of refinement steps is equal to 2.

MKL_DSS_CONJUGATE_SOLVE option added to the parameter *opt* enables solving a conjugate transposed system $A^HX = B$ based on the factorization of the matrix A. This option is equivalent to the parameter *iparm*(12)= 1in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

MKL_DSS_TRANSPOSE_SOLVE option added to the parameter *opt* enables solving a transposed system $A^TX = B$ based on the factorization of the matrix A. This option is equivalent to the parameter *iparm*(12)= 2in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

Input Parameters

handle

TYPE (MKL_DSS_HANDLE), INTENT(INOUT)

Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).

opt

INTEGER, INTENT(IN)

Parameter to pass the DSS options.

nRhs

INTEGER, INTENT(IN)

Number of the right-hand sides in the system of linear equations.

rRhsValues

REAL*8

REAL(KIND=4), INTENT(IN) or

REAL(KIND=8), INTENT(IN)

Array of size *nRows* * *nRhs*. Contains real right-hand side vectors. Real data, single or double precision as it is specified by the parameter *opt* in the routine dss_create.

cRhsValues

COMPLEX*16

COMPLEX(KIND=4), INTENT(IN) or

COMPLEX(KIND=8), INTENT(IN)

Array of size *nRows* * *nRhs*. Contains complex right-hand side vectors. Complex data, single or double precision as it is specified by the parameter *opt* in the routine dss_create.

RhsValues

REAL(KIND=4), INTENT(IN), or

REAL(KIND=8), INTENT(IN), or

COMPLEX(KIND=4), INTENT(IN), or

COMPLEX(KIND=8), INTENT(IN)

Array of size *nRows* * *nRhs*. Contains right-hand side vectors. Real or complex data, single or double precision as it is specified by the parameter *opt* in the routine dss_create.

Output Parameters

rSolValues

REAL(KIND=4), INTENT(OUT) or

REAL(KIND=8), INTENT(OUT)

Array of size *nCols* * *nRhs*. Contains real solution vectors. Real data, single or double precision as it is specified by the parameter *opt* in the routine dss_create.

cSolValues

COMPLEX(KIND=4), INTENT(OUT) or

COMPLEX(KIND=8), INTENT(OUT)

Array of size *nCols* * *nRhs*. Contains complex solution vectors. Complex data, single or double precision as it is specified by the parameter *opt* in the routine dss_create.

SolValues

REAL(KIND=4), INTENT(OUT), or

REAL(KIND=8), INTENT(OUT), or

COMPLEX(KIND=4), INTENT(OUT), or

COMPLEX(KIND=8), INTENT(OUT)

Array of size *nCols* * *nRhs*. Contains solution vectors. Real or complex data, single or double precision as it is specified by the parameter *opt* in the routine dss_create.

Return Values

MKL_DSS_SUCCESS

MKL_DSS_STATE_ERR

MKL_DSS_INVALID_OPTION

MKL_DSS_OUT_OF_MEMORY

MKL_DSS_DIAG_ERR

MKL_DSS_FAILURE

MKL_DSS_MSG_LVL_ERR

MKL_DSS_TERM_LVL_ERR

MKL_DSS_OOC_MEM_ERR

MKL_DSS_OOC_OC_ERR

MKL_DSS_OOC_RW_ERR

dss_delete

Deletes all of the data structures created during the solutions process.

Syntax

`call dss_delete(handle, opt)`

Include Files

- `mkl.fi, mkl_dss.f90`

Description

The routine `dss_delete` deletes all data structures created during the solving process.

Input Parameters

opt

`INTEGER, INTENT(IN)`

Parameter to pass the DSS options. The default value is `MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR`.

Output Parameters

handle

`TYPE (MKL_DSS_HANDLE), INTENT(INOUT)`

Pointer to the data structure storing internal DSS results (`MKL_DSS_HANDLE`).

Return Values

MKL_DSS_SUCCESS

MKL_DSS_STATE_ERR

MKL_DSS_INVALID_OPTION

MKL_DSS_OUT_OF_MEMORY

MKL_DSS_MSG_LVL_ERR

MKL_DSS_TERM_LVL_ERR

dss_statistics

Returns statistics about various phases of the solving process.

Syntax

```
call dss_statistics(handle, opt, statArr, retValues)
```

Include Files

- mkl.fi, mkl_dss.f90

Description

The dss_statistics routine returns statistics about various phases of the solving process. This routine gathers the following statistics:

- time taken to do reordering,
- time taken to do factorization,
- duration of problem solving,
- determinant of the symmetric indefinite input matrix,
- inertia of the symmetric indefinite input matrix,
- number of floating point operations taken during factorization,
- total peak memory needed during the analysis and symbolic factorization,
- permanent memory needed from the analysis and symbolic factorization,
- memory consumption for the factorization and solve phases.

Statistics are returned in accordance with the input string specified by the parameter *statArr*. The value of the statistics is returned in double precision in a return array, which you must allocate beforehand.

For multiple statistics, multiple string constants separated by commas can be used as input. Return values are put into the return array in the same order as specified in the input string.

Statistics can only be requested at the appropriate stages of the solving process. For example, requesting FactorTime before a matrix is factored leads to an error.

The following table shows the point at which each individual statistics item can be requested:

Statistics Calling Sequences

Type of Statistics	When to Call
ReorderTime	After dss_reorder is completed successfully.
FactorTime	After dss_factor_real or dss_factor_complex is completed successfully.
SolveTime	After dss_solve_real or dss_solve_complex is completed successfully.
Determinant	After dss_factor_real or dss_factor_complex is completed successfully.
Inertia	After dss_factor_real is completed successfully and the matrix is real, symmetric, and indefinite.
Flops	After dss_factor_real or dss_factor_complex is completed successfully.
Peakmem	After dss_reorder is completed successfully.
Factormem	After dss_reorder is completed successfully.
Solvemem	After dss_factor_real or dss_factor_complex is completed successfully.

Input Parameters

handle — TYPE (MKL_DSS_HANDLE), INTENT(IN)

Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).

opt

INTEGER, INTENT(IN)

Parameter to pass the DSS options.

statArr

INTEGER, INTENT(IN)

Input string that defines the type of the returned statistics. The parameter can include one or more of the following string constants (case of the input string has no effect):

`ReorderTime`	Amount of time taken to do the reordering.
`FactorTime`	Amount of time taken to do the factorization.
`SolveTime`	Amount of time taken to solve the problem after factorization.
`Determinant`	Determinant of the matrix *A*. For real matrices: the determinant is returned as `det_pow`, `det_base` in two consecutive return array locations, where `1.0` ≤ `abs(`*det_base*`) < 10.0` and `determinant =` *det_base*`*10`$^{(det\_pow)}$. For complex matrices: the determinant is returned as *det_pow*, *det_re*, *det_im* in three consecutive return array locations, where `1.0` ≤`abs(`*det_re*`) + abs(`*det_im*`) < 10.0` and `determinant = (`*det_re*`,` *det_im*`)*10`$^{(det\_pow)}$.
`Inertia`	Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers `(`*p*`,`*n*`,`*z*`)`, where *p* is the number of positive eigenvalues, *n* is the number of negative eigenvalues, and *z* is the number of zero eigenvalues. `Inertia` is returned as three consecutive return array locations *p*, *n*, *z*. Computing inertia can lead to incorrect results for matrixes with a cluster of eigenvalues which are near 0. `Inertia` of a *k*-by-*k* real symmetric positive definite matrix is always `(`*k*`, 0, 0)`. Therefore `Inertia` is returned only in cases of real symmetric indefinite matrices. For all other matrix types, an error message is returned.
`Flops`	Number of floating point operations performed during the factorization.
`Peakmem`	Total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase.

`Factormem`	Permanent memory in kilobytes that the solver needs from the analysis and symbolic factorization phase in the factorization and solve phases.
`Solvemem`	Total double precision memory consumption (kilobytes) of the solver for the factorization and solve phases.

NOTE
To avoid problems in passing strings from Fortran to C, Fortran users must call the `mkl_cvt_to_null_terminated_str` routine before calling `dss_statistics`. Refer to the description of `mkl_cvt_to_null_terminated_str` for details.

Output Parameters

`retValues`	`REAL(KIND=8), INTENT(OUT)` Value of the statistics returned.

Finding 'time used to reorder' and 'inertia' of a matrix

The example below illustrates the use of the `dss_statistics` routine.

To find the above values, call `dss_statistics`(*`handle`*, *`opt`*, *`statArr`*, *`retValue`*), where *`staArr`* is "`ReorderTime,Inertia`"

In this example, *`retValue`* has the following values:

`retValue``[0]`	Time to reorder.
`retValue``[1]`	Positive Eigenvalues.
`retValue``[2]`	Negative Eigenvalues.
`retValue``[3]`	Zero Eigenvalues.

Return Values

`MKL_DSS_SUCCESS`

`MKL_DSS_INVALID_OPTION`

`MKL_DSS_STATISTICS_INVALID_MATRIX`

`MKL_DSS_STATISTICS_INVALID_STATE`

`MKL_DSS_STATISTICS_INVALID_STRING`

`MKL_DSS_MSG_LVL_ERR`

`MKL_DSS_TERM_LVL_ERR`

mkl_cvt_to_null_terminated_str

Passes character strings from Fortran routines to C routines.

Syntax

`mkl_cvt_to_null_terminated_str (`*`destStr`*`, `*`destLen`*`, `*`srcStr`*`)`

Include Files

- `mkl.fi`, `mkl_dss.f90`

Description

The routine `mkl_cvt_to_null_terminated_str` passes character strings from Fortran routines to C routines. The strings are converted into integer arrays before being passed to C. Using this routine avoids the problems that can occur on some platforms when passing strings from Fortran to C. The use of this routine is highly recommended.

Input Parameters

destLen	`INTEGER`. Length of the output array *destStr*.
srcStr	`STRING`. Input string.

Output Parameters

destStr	`INTEGER`. One-dimensional array of integers.

Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS)

Intel® oneAPI Math Kernel Library (oneMKL) supports iterative sparse solvers (ISS) based on the reverse communication interface (RCI), referred to here as the RCI ISS interface. The RCI ISS interface implements a group of user-callable routines that are used in the step-by-step solving process of a symmetric positive definite system (RCI conjugate gradient solver, or RCI CG), and of a non-symmetric indefinite (non-degenerate) system (RCI flexible generalized minimal residual solver, or RCI FGMRES) of linear algebraic equations. This interface uses the general RCI scheme described in [Dong95].

See the Appendix A Linear Solvers Basics for discussion of terms and concepts related to the ISS routines.

The term *RCI* indicates that when the solver needs the results of certain operations (for example, matrix-vector multiplications), the user performs them and passes the result to the solver. This makes the solver more universal as it is independent of the specific implementation of the operations like the matrix-vector multiplication. To perform such operations, the user can use the built-in sparse matrix-vector multiplications and triangular solvers routines described in Sparse BLAS Level 2 and Level 3 Routines.

> **NOTE**
> The RCI CG solver is implemented in two versions: for system of equations with a single right-hand side, and for systems of equations with multiple right-hand sides.
>
> The CG method may fail to compute the solution or compute the wrong solution if the matrix of the system is not symmetric and not positive definite.
>
> The FGMRES method may fail if the matrix is degenerate.

Table "RCI CG Interface Routines" lists the names of the routines, and describes their general use.

RCI ISS Interface Routines

Routine	Description
dcg_init, dcgmrhs_init, dfgmres_init	Initializes the solver.
dcg_check, dcgmrhs_check, dfgmres_check	Checks the consistency and correctness of the user defined data.
dcg, dcgmrhs, dfgmres	Computes the approximate solution vector.
dcg_get, dcgmrhs_get, dfgmres_get	Retrieves the number of the current iteration.

The Intel® oneAPI Math Kernel Library (oneMKL) RCI ISS interface routines are normally invoked in this order:

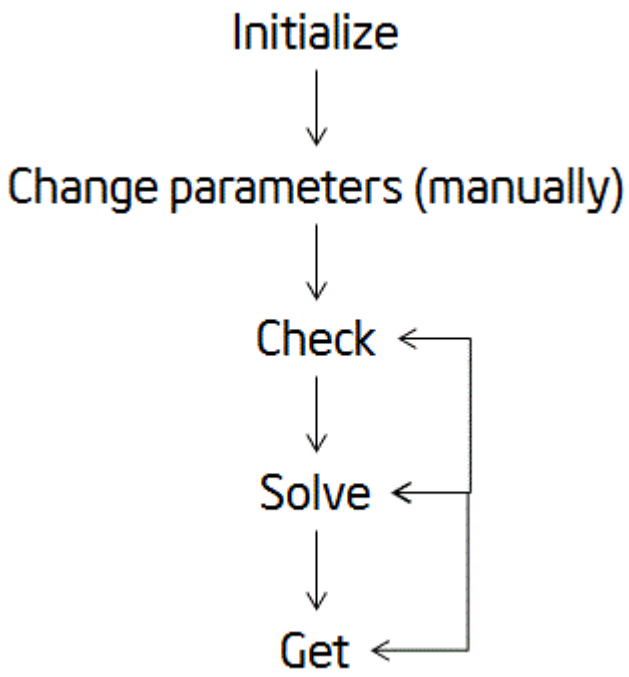
1. `<system_type>_init`
2. `<system_type>_check`
3. `<system_type>`
4. `<system_type>_get`

Advanced users can change that order if they need it. Others should follow the above order of calls.

The following diagram indicates the typical order in which the RCI ISS interface routines are invoked.

__border__top

Typical Order for Invoking RCI ISS interface Routines



See the code examples that use the RCI ISS interface routines to solve systems of linear equations in the Intel® oneAPI Math Kernel Library (oneMKL) installation directory.

- `examples/solverf/source`

CG Interface Description

All types in this documentation refer to the common Fortran types, `INTEGER`, and `DOUBLE PRECISION`.

Each routine for the RCI CG solver is implemented in two versions: for a system of equations with a single right-hand side (SRHS), and for a system of equations with multiple right-hand sides (MRHS). The names of routines for a system with MRHS contain the suffix `mrhs`.

Routine Options

All of the RCI CG routines have common parameters for passing various options to the routines (see CG Common Parameters). The values for these parameters can be changed during computations.

User Data Arrays

Many of the RCI CG routines take arrays of user data as input. For example, user arrays are passed to the routine dcgto compute the solution of a system of linear algebraic equations. The Intel® oneAPI Math Kernel Library (oneMKL) RCI CG routines do not make copies of the user input arrays to minimize storage requirements and improve overall run-time efficiency.

CG Common Parameters

NOTE
The default and initial values listed below are assigned to the parameters by calling the dcg_init/dcgmrhs_init routine.

n INTEGER, this parameter sets the size of the problem in the dcg_init/dcgmrhs_init routine. All the other routines use the *ipar*(1) parameter instead. Note that the coefficient matrix *A* is a square matrix of size *n***n*.

x DOUBLE PRECISION array of size *n* for SRHS, or matrix of size (*n***nrhs*) for MRHS. This parameter contains the current approximation to the solution. Before the first call to the dcg/dcgmrhs routine, it contains the initial approximation to the solution.

nrhs INTEGER, this parameter sets the number of right-hand sides for MRHS routines.

b DOUBLE PRECISION array containing a single right-hand side vector, or matrix of size *n*nrhs* containing right-hand side vectors.

RCI_request INTEGER, this parameter gives information about the result of work of the RCI CG routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions:

RCI_request= 1	multiply the matrix by *tmp* (1:*n*,1), put the result in *tmp*(1:*n*,2), and return the control to the dcg/dcgmrhs routine;
RCI_request= 2	to perform the stopping tests. If they fail, return the control to the dcg/dcgmrhs routine. If the stopping tests succeed, it indicates that the solution is found and stored in the *x* array;
RCI_request= 3	for SRHS: apply the preconditioner to *tmp*(1:*n*,3), put the result in *tmp*(1:*n*,4), and return the control to the dcg routine; for MRHS: apply the preconditioner to *tmp*(:,3+*ipar*(3)), put the result in *tmp*(:,3), and return the control to the dcgmrhs routine.

Note that the dcg_get/dcgmrhs_get routine does not change the parameter *RCI_request*. This enables use of this routine inside the *reverse communication* computations.

ipar INTEGER array, of size 128 for SRHS, and of size (128+2*nrhs) for MRHS. This parameter specifies the integer set of data for the RCI CG computations:

ipar(1) specifies the size of the problem. The dcg_init/dcgmrhs_init routine assigns *ipar*(1)=*n*. All the other routines use this parameter instead of *n*. There is no default value for this parameter.

ipar(2) specifies the type of output for error and warning messages generated by the RCI CG routines. The default value 6 means that all messages are displayed on the screen. Otherwise, the error and warning messages are written to the newly created files dcg_errors.txt and dcg_check_warnings.txt, respectively. Note that if *ipar*(6) and *ipar*(7) parameters are set to 0, error and warning messages are not generated at all.

ipar(3) for SRHS: contains the current stage of the RCI CG computations. The initial value is 1;

for MRHS: contains the number of the right-hand side for which the calculations are currently performed.

WARNING
Avoid altering this variable during computations.

ipar(4) contains the current iteration number. The initial value is 0.

ipar(5) specifies the maximum number of iterations. The default value is min(150, *n*).

ipar(6) if the value is not equal to 0, the routines output error messages in accordance with the parameter *ipar*(2). Otherwise, the routines do not output error messages at all, but return a negative value of the parameter *RCI_request*. The default value is 1.

ipar(7) if the value is not equal to 0, the routines output warning messages in accordance with the parameter *ipar*(2). Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter *RCI_request*. The default value is 1.

ipar(8) if the value is not equal to 0, the dcg/dcgmrhs routine performs the stopping test for the maximum number of iterations: *ipar*(4) ≤

ipar(5). Otherwise, the method is stopped and the corresponding value is assigned to the *RCI_request*. If the value is 0, the routine does not perform this stopping test. The default value is 1.

ipar(9) — if the value is not equal to 0, the dcg/dcgmrhs routine performs the residual stopping test: *dpar*(5) ≤ *dpar*(4)= *dpar*(1)***dpar*(3)+ *dpar*(2). Otherwise, the method is stopped and corresponding value is assigned to the *RCI_request*. If the value is 0, the routine does not perform this stopping test. The default value is 0.

ipar(10) — if the value is not equal to 0, the dcg/dcgmrhs routine requests a user-defined stopping test by setting the output parameter *RCI_request*=2. If the value is 0, the routine does not perform the user defined stopping test. The default value is 1.

NOTE
At least one of the parameters *ipar*(8)-*ipar*(10) must be set to 1.

ipar(11) — if the value is equal to 0, the dcg/dcgmrhs routine runs the non-preconditioned version of the corresponding CG method. Otherwise, the routine runs the preconditioned version of the CG method, and by setting the output parameter *RCI_request*=3, indicates that you must perform the preconditioning step. The default value is 0.

ipar(12:128) — are reserved and not used in the current RCI CG SRHS and MRHS routines.

NOTE
For future compatibility, you must declare the array *ipar* with length 128 for a single right-hand side.

ipar(12:128+2**nrhs*) — are reserved for internal use in the current RCI CG SRHS and MRHS routines.

NOTE
For future compatibility, you must declare the array *ipar* with length 128+2**nrhs* for multiple right-hand sides.

dpar

DOUBLE PRECISION array, for SRHS of size 128, for MRHS of size (128+2*nrhs); this parameter is used to specify the double precision set of data for the RCI CG computations, specifically:

dpar(1)	specifies the relative tolerance. The default value is $1.0X10^{-6}$.
dpar(2)	specifies the absolute tolerance. The default value is 0.0.
dpar(3)	specifies the square norm of the initial residual (if it is computed in the dcg/dcgmrhs routine). The initial value is 0.0.
dpar(4)	service variable equal to *dpar*(1)*dpar(3)+*dpar*(2) (if it is computed in the dcg/dcgmrhs routine). The initial value is 0.0.
dpar(5)	specifies the square norm of the current residual. The initial value is 0.0.
dpar(6)	specifies the square norm of residual from the previous iteration step (if available). The initial value is 0.0.
dpar(7)	contains the *alpha* parameter of the CG method. The initial value is 0.0.
dpar(8)	contains the *beta* parameter of the CG method, it is equal to *dpar*(5)/*dpar*(6) The initial value is 0.0.
dpar(9:128)	are reserved and not used in the current RCI CG SRHS and MRHS routines.

NOTE
For future compatibility, you must declare the array *dpar* with length 128 for a single right-hand side.

dpar(9:128+2*nrhs) (9:128 + 2*nrhs)	are reserved for internal use in the current RCI CG SRHS and MRHS routines.

NOTE
For future compatibility, you must declare the array *dpar* with length 128+2*nrhs for multiple right-hand sides.

tmp

DOUBLE PRECISION array of size (n, 4) for SRHS, and (n, (3+nrhs)) for MRHS. This parameter is used to supply the double precision temporary space for the RCI CG computations, specifically:

tmp(:,1)	specifies the current search direction. The initial value is 0.0.
tmp(:,2)	contains the matrix multiplied by the current search direction. The initial value is 0.0.
tmp(:,3)	contains the current residual. The initial value is 0.0.
tmp(:,4)	contains the inverse of the preconditioner applied to the current residual for the SRHS version of CG. There is no initial value for this parameter.
tmp(:,4:3+*nrhs*)	contains the inverse of the preconditioner applied to the current residual for the MRHS version of CG. There is no initial value for this parameter.

NOTE
You can define this array in the code using RCI CG SRHS as DOUBLE PRECISION*tmp*(*n*,3) if you run only non-preconditioned CG iterations.

Schemes of Using the RCI CG Routines

The following pseudocode shows the general schemes of using the RCI CG routines for the SRHS case. The MRHS is similar (see the example code for more details).

```
...
generate matrix A
generate preconditioner C (optional)
   call dcg_init(n, x, b, RCI_request, ipar, dpar, tmp)
   change parameters in ipar, dpar if necessary
   call dcg_check(n, x, b, RCI_request, ipar, dpar, tmp)
1  call dcg(n, x, b, RCI_request, ipar, dpar, tmp)
   if (RCI_request.eq.1) then
    multiply the matrix A by tmp(1:n,1) and put the result in tmp(1:n,2)
   It is possible to use MKL Sparse BLAS Level 2 subroutines for this operation
c  proceed with CG iterations
     goto 1
   endif
   if (RCI_request.eq.2)then
    do the stopping test
    if (test not passed) then
c  proceed with CG iterations
```

```
     go to 1
    else
c  stop CG iterations
     goto 2
    endif
   endif
   if (RCI_request.eq.3) then (optional)
   apply the preconditioner C inverse to tmp(1:n,3) and put the result in tmp(1:n,4)
c  proceed with CG iterations
    goto 1
   end
```

2 call dcg_get(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*, *itercount*)

current iteration number is in *itercount*

the computed approximation is in the array *x*

FGMRES Interface Description

All types in this documentation refer to the common Fortran types: `INTEGER` and `DOUBLE PRECISION`.

Routine Options

All of the RCI FGMRES routines have common parameters for passing various options to the routines (see FGMRES Common Parameters). The values for these parameters can be changed during computations.

User Data Arrays

Many of the RCI FGMRES routines take arrays of user data as input. For example, user arrays are passed to the routine `dfgmres`to compute the solution of a system of linear algebraic equations. To minimize storage requirements and improve overall run-time efficiency, the Intel® oneAPI Math Kernel Library (oneMKL) RCI FGMRES routines do not make copies of the user input arrays.

FGMRES Common Parameters

NOTE
The default and initial values listed below are assigned to the parameters by calling the `dfgmres_init` routine.

n — `INTEGER`, this parameter sets the size of the problem in the `dfgmres_init` routine. All the other routines use the *ipar*(1) parameter instead. Note that the coefficient matrix *A* is a square matrix of size *n***n*.

x — `DOUBLE PRECISION` array, this parameter contains the current approximation to the solution vector. Before the first call to the `dfgmres` routine, it contains the initial approximation to the solution vector.

b

DOUBLE PRECISION array, this parameter contains the right-hand side vector. Depending on user requests (see the parameter *ipar*(13)), it might contain the approximate solution after execution.

RCI_request

INTEGER, this parameter gives information about the result of work of the RCI FGMRES routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions:

RCI_request= 1	multiply the matrix by *tmp*(*ipar*(22)), put the result in *tmp*(*ipar*(23)), and return the control to the dfgmres routine;
RCI_request= 2	perform the stopping tests. If they fail, return the control to the dfgres routine. Otherwise, the solution can be updated by a subsequent call to dfgmres_get routine;
RCI_request= 3	apply the preconditioner to *tmp*(*ipar*(22)), put the result in *tmp*(*ipar*(23)), and return the control to the dfgmres routine.
RCI_request= 4	check if the norm of the current orthogonal vector is zero, within the rounding or computational errors. Return the control to the dfgmres routine if it is not zero, otherwise complete the solution process by calling dfgmres_get routine.

ipar(128)[128]

INTEGER array, this parameter specifies the integer set of data for the RCI FGMRES computations:

ipar(1)	specifies the size of the problem. The dfgmres_init routine assigns *ipar*(1)=*n*. All the other routines uses this parameter instead of *n*. There is no default value for this parameter.
ipar(2)	specifies the type of output for error and warning messages that are generated by the RCI FGMRES routines. The default value 6 means that all messages are displayed on the screen. Otherwise the error and warning messages are written to the newly created file MKL_RCI_FGMRES_Log.txt. Note that if *ipar*(6) and *ipar*(7) parameters are set to 0, error and warning messages are not generated at all.
ipar(3)	contains the current stage of the RCI FGMRES computations. The initial value is 1.

WARNING
Avoid altering this variable during computations.

ipar(4) contains the current iteration number. The initial value is 0.

ipar(5) specifies the maximum number of iterations. The default value is *min* (150,*n*).

ipar(6) if the value is not 0, the routines output error messages in accordance with the parameter *ipar*(2). If it is 0, the routines do not output error messages at all, but return a negative value of the parameter *RCI_request*. The default value is 1.

ipar(7) if the value is not 0, the routines output warning messages in accordance with the parameter *ipar*(2). Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter *RCI_request*. The default value is 1.

ipar(8) if the value is not equal to 0, the dfgmres routine performs the stopping test for the maximum number of iterations: *ipar*(4) ≤*ipar*(5). If the value is 0, the dfgmres routine does not perform this stopping test. The default value is 1.

ipar(9) if the value is not 0, the dfgmres routine performs the residual stopping test: *dpar*(5) ≤*dpar*(4).If the value is 0, the dfgmres routine does not perform this stopping test. The default value is 0.

ipar(10) if the value is not 0, the dfgmres routine indicates that the user-defined stopping test should be performed by setting *RCI_request*=2. If the value is 0, the dfgmres routine does not perform the user-defined stopping test. The default value is 1.

NOTE
At least one of the parameters *ipar*(8)-*ipar*(10) must be set to 1.

ipar(11) if the value is 0, the dfgmres routine runs the non-preconditioned version of the FGMRES method. Otherwise, the routine runs the preconditioned version of the FGMRES method,

and requests that you perform the preconditioning step by setting the output parameter *RCI_request*=3. The default value is 0.

ipar(12) if the value is not equal to 0, the dfgmres routine performs the automatic test for zero norm of the currently generated vector: *dpar*(7)≤*dpar*(8), where *dpar*(8) contains the tolerance value. Otherwise, the routine indicates that you must perform this check by setting the output parameter *RCI_request*=4. The default value is 0.

ipar(13) if the value is equal to 0, the dfgmres_get routine updates the solution to the vector *x* according to the computations done by the dfgmres routine. If the value is positive, the routine writes the solution to the right-hand side vector *b*. If the value is negative, the routine returns only the number of the current iteration, and does not update the solution. The default value is 0.

NOTE
It is possible to call the dfgmres_get routine at any place in the code, but you must pay special attention to the parameter *ipar*(13). The RCI FGMRES iterations can be continued after the call to dfgmres_get routine only if the parameter *ipar*(13) is not equal to zero. If *ipar*(13) is positive, then the updated solution overwrites the right-hand side in the vector *b*. If you want to run the restarted version of FGMRES with the same right-hand side, then it must be saved in a different memory location before the first call to the dfgmres_get routine with positive *ipar*(13).

ipar(14) contains the internal iteration counter that counts the number of iterations before the restart takes place. The initial value is 0.

WARNING
Do not alter this variable during computations.

ipar(15) specifies the number of the non-restarted FGMRES iterations. To run the restarted version of the FGMRES method, assign the number of

iterations to *ipar*(15) before the restart. The default value is *min*(150, *n*), which means that by default the non-restarted version of FGMRES method is used.

ipar(16) — service variable specifying the location of the rotated Hessenberg matrix from which the matrix stored in the packed format (see Matrix Arguments in the Appendix B for details) is started in the *tmp* array.

ipar(17) — service variable specifying the location of the rotation cosines from which the vector of cosines is started in the *tmp* array.

ipar(18) — service variable specifying the location of the rotation sines from which the vector of sines is started in the *tmp* array.

ipar(19) — service variable specifying the location of the rotated residual vector from which the vector is started in the *tmp* array.

ipar(20) — service variable, specifies the location of the least squares solution vector from which the vector is started in the *tmp* array.

ipar(21) — service variable specifying the location of the set of preconditioned vectors from which the set is started in the *tmp* array. The memory locations in the *tmp* array starting from *ipar*(21) are used only for the preconditioned FGMRES method.

ipar(22) — specifies the memory location from which the first vector (source) used in operations requested via *RCI_request* is started in the *tmp* array.

ipar(23) — specifies the memory location from which the second vector (output) used in operations requested via *RCI_request* is started in the *tmp* array.

ipar(24:128) — are reserved and not used in the current RCI FGMRES routines.

NOTE
You must declare the array *ipar* with length 128. While defining the array in the code as INTEGER*ipar*(23) works, there is no guarantee of future compatibility with Intel® oneAPI Math Kernel Library (oneMKL).

dpar(128)

DOUBLE PRECISION array, this parameter specifies the double precision set of data for the RCI CG computations, specifically:

dpar(1)	specifies the relative tolerance. The default value is 1.0e-6.
dpar(2)	specifies the absolute tolerance. The default value is 0.0e-0.
dpar(3)	specifies the Euclidean norm of the initial residual (if it is computed in the dfgmres routine). The initial value is 0.0.
dpar(4)	service variable equal to *dpar*(1)**dpar*(3)+*dpar*(2) (if it is computed in the dfgmres routine). The initial value is 0.0.
dpar(5)	specifies the Euclidean norm of the current residual. The initial value is 0.0.
dpar(6)	specifies the Euclidean norm of residual from the previous iteration step (if available). The initial value is 0.0.
dpar(7)	contains the norm of the generated vector. The initial value is 0.0.

NOTE
In terms of [Saad03] this parameter is the coefficient $h_{k+1,k}$ of the Hessenberg matrix.

dpar(8)	contains the tolerance for the zero norm of the currently generated vector. The default value is 1.0e-12.
dpar(9:128)	are reserved and not used in the current RCI FGMRES routines.

NOTE
You must declare the array *dpar* with length 128. While defining the array in the code as DOUBLE PRECISION *dpar*(8) works, there is no guarantee of future compatibility with Intel® oneAPI Math Kernel Library (oneMKL).

tmp

DOUBLE PRECISION array of size ((2**ipar*(15)+1)**n* + *ipar*(15)*(*ipar*(15)+9)/2 + 1)) used to supply the double precision temporary space for the RCI FGMRES computations, specifically:

tmp(1:ipar(16)*-1)*	contains the sequence of vectors generated by the FGMRES method. The initial value is 0.0.

tmp(ipar(16):ipar(17)-1)	contains the rotated Hessenberg matrix generated by the FGMRES method; the matrix is stored in the packed format. There is no initial value for this part of *tmp* array.
tmp(ipar(17):ipar(18)-1)	contains the rotation cosines vector generated by the FGMRES method. There is no initial value for this part of *tmp* array.
tmp(ipar(18):ipar(19)-1)	contains the rotation sines vector generated by the FGMRES method. There is no initial value for this part of *tmp* array.
tmp(ipar(19):ipar(20)-1)	contains the rotated residual vector generated by the FGMRES method. There is no initial value for this part of *tmp* array.
tmp(ipar(20):ipar(21)-1)	contains the solution vector to the least squares problem generated by the FGMRES method. There is no initial value for this part of *tmp* array.
tmp(ipar(21):)	contains the set of preconditioned vectors generated for the FGMRES method by the user. This part of *tmp* array is not used if the non-preconditioned version of FGMRES method is called. There is no initial value for this part of *tmp* array.

NOTE
You can define this array in the code as `DOUBLE PRECISION tmp((2*ipar(15)+1)*n + ipar(15)*(ipar(15)+9)/2 + 1))` if you run only non-preconditioned FGMRES iterations.

Scheme of Using the RCI FGMRES Routines

The following pseudocode shows the general scheme of using the RCI FGMRES routines.

```
...
generate matrix A
generate preconditioner C (optional)
  call dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)
   change parameters in ipar, dpar if necessary
   call dfgmres_check(n, x, b, RCI_request, ipar, dpar, tmp)
1  call dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)
   if (RCI_request.eq.1) then
     multiply the matrix A by tmp(ipar(22)) and put the result in tmp(ipar(23))
```

It is possible to use MKL Sparse BLAS Level 2 subroutines for this operation

```
c  proceed with FGMRES iterations
   goto 1
  endif
  if (RCI_request.eq.2) then
   do the stopping test
   if (test not passed) then
c  proceed with FGMRES iterations
    go to 1
   else
c  stop FGMRES iterations
    goto 2
   endif
  endif
  if (RCI_request.eq.3) then (optional)
  apply the preconditioner C inverse to tmp(ipar(22)) and put the result in tmp(ipar(23))
c  proceed with FGMRES iterations
   goto 1
  endif
  if (RCI_request.eq.4) then
  check the norm of the next orthogonal vector, it is contained in dpar(7)
   if (the norm is not zero up to rounding/computational errors) then
c  proceed with FGMRES iterations
    goto 1
   else
c  stop FGMRES iterations
    goto 2
   endif
  endif
```

2 call `dfgmres_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)`

current iteration number is in *itercount*

the computed approximation is in the array *x*

NOTE

For the FGMRES method, the array *x* initially contains the current approximation to the solution. It can be updated only by calling the routine `dfgmres_get`, which updates the solution in accordance with the computations performed by the routine `dfgmres`.

The above pseudocode demonstrates two main differences in the use of RCI FGMRES interface comparing with the CG Interface Description. The first difference relates to *RCI_request*=3: it uses different locations in the *tmp* array, which is two-dimensional for CG and one-dimensional for FGMRES. The second difference relates to *RCI_request*=4: the RCI CG interface never produces *RCI_request*=4.

RCI ISS Routines

dcg_init

Initializes the solver.

Syntax

`dcg_init(n, x, b, RCI_request, ipar, dpar, tmp)`

Include Files

- Fortran: `mkl_rci.fi`, `mkl_rci.f90`

Description

The routine `dcg_init`initializes the solver. After initialization, all subsequent invocations of the Intel® oneAPI Math Kernel Library (oneMKL) RCI CG routines use the values of all parameters returned by the routine`dcg_init`. Advanced users can skip this step and set the values in the *ipar* and *dpar* arrays directly.

> **Caution**
> You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dcg_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

n	`INTEGER`. Sets the size of the problem.
x	`DOUBLE PRECISION`. Array of size *n*. Contains the initial approximation to the solution vector. Normally it is equal to 0 or to *b*.
b	`DOUBLE PRECISION`. Array of size *n*. Contains the right-hand side vector.

Output Parameters

RCI_request	`INTEGER`. Gives information about the result of the routine.
ipar	`INTEGER` . Array of size `128`. Refer to the CG Common Parameters.
dpar	`DOUBLE PRECISION`. Array of size `128`. Refer to the CG Common Parameters.
tmp	`DOUBLE PRECISION` . Array of size `(n,4)`. Refer to the CG Common Parameters.

Return Values

RCI_request= 0	Indicates that the task completed normally.

RCI_request= -10000	Indicates failure to complete the task.

dcg_check

Checks consistency and correctness of the user defined data.

Syntax

`dcg_check(n, x, b, RCI_request, ipar, dpar, tmp)`

Include Files

- Fortran: `mkl_rci.fi`, `mkl_rci.f90`

Description

The routine `dcg_check` checks consistency and correctness of the parameters to be passed to the solver routine `dcg`. However this operation does not guarantee that the solver returns the correct result. It only reduces the chance of making a mistake in the parameters of the method. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

If none of the stopping criteria (*ipar*(8)-*ipar*(10)) has been enabled, both *ipar*(8) and *ipar*(9) will be set to 1.

Input Parameters

ipar	Array of size 128. Refer to the FGMRES Common Parameters.
n	`INTEGER`. Sets the size of the problem.
x	`DOUBLE PRECISION`. Array of size *n*. Contains the initial approximation to the solution vector. Normally it is equal to 0 or to *b*.
b	`DOUBLE PRECISION`. Array of size *n*. Contains the right-hand side vector.

Output Parameters

RCI_request	`INTEGER`. Gives information about result of the routine.
ipar	`INTEGER`. Array of size `128`. Refer to the CG Common Parameters. Only *ipar*(8)-*ipar*(9) might be changed
dpar	`DOUBLE PRECISION`. Array of size `128`. Refer to the CG Common Parameters.
tmp	`DOUBLE PRECISION`. Array of size `(n,4)`. Refer to the CG Common Parameters.

Return Values

RCI_request= 0	Indicates that the task completed normally.
RCI_request= -1100	Indicates that the task is interrupted and the errors occur.
RCI_request= -1001	Indicates that there are some warning messages.

RCI_request= -1010	Indicates that the routine changed some parameters to make them consistent or correct.
RCI_request= -1011	Indicates that there are some warning messages and that the routine changed some parameters.

dcg

Computes the approximate solution vector.

Syntax

`dcg(n, x, b, RCI_request, ipar, dpar, tmp)`

Include Files

- Fortran: `mkl_rci.fi`, `mkl_rci.f90`

Description

The `dcg` routine computes the approximate solution vector using the CG method [Young71]. The routine `dcg` uses the vector in the array *x* before the first call as an initial approximation to the solution. The parameter *RCI_request* gives you information about the task completion and requests results of certain operations that are required by the solver.

Note that lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

Input Parameters

n	`INTEGER`. Sets the size of the problem.
x	`DOUBLE PRECISION` . Array of size *n*. Contains the initial approximation to the solution vector.
b	`DOUBLE PRECISION` . Array of size *n*. Contains the right-hand side vector.
tmp	`DOUBLE PRECISION` . Array of size `(`*n*, 4). Refer to the CG Common Parameters.

Output Parameters

RCI_request	`INTEGER`. Gives information about result of work of the routine.
x	`DOUBLE PRECISION` . Array of size *n*. Contains the updated approximation to the solution vector.
ipar	`INTEGER` . Array of size *128*. Refer to the CG Common Parameters.
dpar	`DOUBLE PRECISION` . Array of size *128*. Refer to the CG Common Parameters.
tmp	`DOUBLE PRECISION` . Array of size `(`*n*,4). Refer to the CG Common Parameters.

Return Values

RCI_request=0	Indicates that the task completed normally and the solution is found and stored in the vector *x*. This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the *RCI_request*= 2.
RCI_request=-1	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.
RCI_request=-2	Indicates that the routine was interrupted because of an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.
RCI_request=- 10	Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value *dpar*(6) was altered outside of the routine, or the dcg_check routine was not called.
RCI_request=-11	Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values *ipar*(8), *ipar*(9), *ipar*(10) were altered outside of the routine, or the dcg_check routine was not called.
RCI_request= 1	Indicates that you must multiply the matrix by *tmp*(1:*n*,1), put the result in the *tmp*(1:*n*,2), and return control back to the routine dcg.
RCI_request= 2	Indicates that you must perform the stopping tests. If they fail, return control back to the dcg routine. Otherwise, the solution is found and stored in the vector *x*.
RCI_request= 3	Indicates that you must apply the preconditioner to *tmp*(:, 3), put the result in the *tmp*(:, 4), and return control back to the routine dcg.

dcg_get

Retrieves the number of the current iteration.

Syntax

dcg_get(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*, *itercount*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The routine dcg_get retrieves the current iteration number of the solutions process.

Input Parameters

n	INTEGER. Sets the size of the problem.

x	DOUBLE PRECISION. Array of size *n*. Contains the approximation vector to the solution.
b	DOUBLE PRECISION. Array of size *n*. Contains the right-hand side vector.
RCI_request	INTEGER. This parameter is not used.
ipar	INTEGER. Array of size 128. Refer to the CG Common Parameters.
dpar	DOUBLE PRECISION. Array of size 128. Refer to the CG Common Parameters.
tmp	DOUBLE PRECISION. Array of size (*n*,4). Refer to the CG Common Parameters.

Output Parameters

itercount	INTEGER. Returns the current iteration number.

Return Values

The routine dcg_get has no return values.

dcgmrhs_init

Initializes the RCI CG solver with MHRS.

Syntax

dcgmrhs_init(*n*, *x*, *nrhs*, *b*, *method*, *RCI_request*, *ipar*, *dpar*, *tmp*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The routine dcgmrhs_initinitializes the solver. After initialization all subsequent invocations of the Intel® oneAPI Math Kernel Library (oneMKL) RCI CG with multiple right-hand sides (MRHS) routines use the values of all parameters that are returned bydcgmrhs_init. Advanced users may skip this step and set the values to these parameters directly in the appropriate routines.

WARNING
You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the dcgmrhs_check routine, but it does not guarantee that the method will work correctly.

Input Parameters

n	INTEGER. Sets the size of the problem.
x	DOUBLE PRECISION. Array of size *n*nrhs*. Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to *b*.
nrhs	INTEGER. Sets the number of right-hand sides.

b	DOUBLE PRECISION. Array of size *n*nrhs*. Contains the right-hand side vectors.
method	INTEGER. Specifies the method of solution: A value of 1 indicates CG with multiple right-hand sides (default value)

Output Parameters

RCI_request	INTEGER. Gives information about the result of the routine.
ipar	INTEGER. Array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
dpar	DOUBLE PRECISION. Array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
tmp	DOUBLE PRECISION. Array of size (*n*, (3+*nrhs*)). Refer to the CG Common Parameters.

Return Values

RCI_request= 0	Indicates that the task completed normally.
RCI_request= -10000	Indicates failure to complete the task.

dcgmrhs_check

Checks consistency and correctness of the user defined data.

Syntax

dcgmrhs_check(*n*, *x*, *nrhs*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The routine dcgmrhs_check checks the consistency and correctness of the parameters to be passed to the solver routine dcgmrhs. While this operation reduces the chance of making a mistake in the parameters, it does not guarantee that the solver returns the correct result.

If you are sure that the correct data is *specified* in the solver parameters, you can skip this operation.

The lengths of all vectors must be defined in a previous call to the dcgmrhs_init routine.

If none of the stopping criteria (*ipar*(8)-*ipar*(10)) has been enabled, both *ipar*(8) and *ipar*(9) will be set to 1.

Input Parameters

n	INTEGER. Sets the size of the problem.
x	DOUBLE PRECISION. Array of size *n*nrhs*. Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to *b*.
nrhs	INTEGER. This parameter sets the number of right-hand sides.

b	DOUBLE PRECISION. Array of size *n*nrhs*. Contains the right-hand side vectors.

Output Parameters

RCI_request	INTEGER. Returns information about the results of the routine.
ipar	INTEGER. Array of size *(128+2*nrhs)*. Refer to the CG Common Parameters. Only *ipar*(8)-*ipar*(9) might be changed.
dpar	DOUBLE PRECISION. Array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
tmp	DOUBLE PRECISION. Array of size (*n*, (3+*nrhs*)). Refer to the CG Common Parameters.

Return Values

RCI_request= 0	Indicates that the task completed normally.
RCI_request= -1100	Indicates that the task is interrupted and the errors occur.
RCI_request= -1001	Indicates that there are some warning messages.
RCI_request= -1010	Indicates that the routine changed some parameters to make them consistent or correct.
RCI_request= -1011	Indicates that there are some warning messages and that the routine changed some parameters.

dcgmrhs

Computes the approximate solution vectors.

Syntax

dcgmrhs(*n*, *x*, *nrhs*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The routine dcgmrhs computes approximate solution vectors using the CG with multiple right-hand sides (MRHS) method [Young71]. The routine dcgmrhs uses the value that was in the *x* before the first call as an initial approximation to the solution. The parameter *RCI_request* gives information about task completion status and requests results of certain operations that are required by the solver.

Note that lengths of all vectors are assumed to have been defined in a previous call to the dcgmrhs_init routine.

Input Parameters

n	INTEGER. Sets the size of the problem, and the sizes of arrays *x* and *b*.
x	DOUBLE PRECISION. Array of size *n*nrhs*. Contains the initial approximation to the solution vectors.

nrhs	INTEGER. Sets the number of right-hand sides.
b	DOUBLE PRECISION. Array of size *n*nrhs*. Contains the right-hand side vectors.
tmp	DOUBLE PRECISION. Array of size (*n*, 3+*nrhs*). Refer to the CG Common Parameters.

Output Parameters

RCI_request	INTEGER. Gives information about result of work of the routine.
x	DOUBLE PRECISION. Array of size (*n* by *nrhs*). Contains the updated approximation to the solution vectors.
ipar	INTEGER. Array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
dpar	DOUBLE PRECISION. Array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
tmp	DOUBLE PRECISION. Array of size (*n*, (3+*nrhs*)). Refer to the CG Common Parameters.

Return Values

RCI_request=0	Indicates that the task completed normally and the solution is found and stored in the vector *x*. This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the *RCI_request*= 2.
RCI_request=-1	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if both tests are requested by the user.
RCI_request=-2	The routine was interrupted because of an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.
RCI_request=- 10	Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value *dpar*(6) was altered outside of the routine, or the dcg_check routine was not called.
RCI_request=-11	Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values *ipar*(8), *ipar*(9), *ipar*(10) were altered outside of the routine, or the dcg_check routine was not called.
RCI_request= 1	Indicates that you must multiply the matrix by *tmp*(1:*n*,1), put the result in the *tmp*(1:*n*,2), and return control back to the routine dcg.
RCI_request= 2	Indicates that you must perform the stopping tests. If they fail, return control back to the dcg routine. Otherwise, the solution is found and stored in the vector *x*.

RCI_request= 3	Indicates that you must apply the preconditioner to *tmp*(:, 3), put the result in the *tmp*(:, 4), and return control back to the routine dcg.

dcgmrhs_get

Retrieves the number of the current iteration.

Syntax

dcgmrhs_get(*n*, *x*, *nrhs*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*, *itercount*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The routine dcgmrhs_get retrieves the current iteration number of the solving process.

Input Parameters

n	INTEGER. Sets the size of the problem.
x	DOUBLE PRECISION. Array of size *n*nrhs*. Contains the initial approximation to the solution vectors.
nrhs	INTEGER. Sets the number of right-hand sides.
b	DOUBLE PRECISION. Array of size *n*nrhs*. Contains the right-hand side .
RCI_request	INTEGER. This parameter is not used.
ipar	INTEGER. Array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
dpar	DOUBLE PRECISION. Array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
tmp	DOUBLE PRECISION. Array of size (*n*, (3+*nrhs*)). Refer to the CG Common Parameters.

Output Parameters

itercount	INTEGER. Array of size *nrhs*. Returns the current iteration number for each right-hand side.

Return Values

The routine dcgmrhs_get has no return values.

dfgmres_init

Initializes the solver.

Syntax

dfgmres_init(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*)

Include Files

- Fortran: `mkl_rci.fi`, `mkl_rci.f90`

Description

The routine `dfgmres_init`initializes the solver. After initialization all subsequent invocations of Intel® oneAPI Math Kernel Library (oneMKL) RCI FGMRES routines use the values of all parameters that are returned by`dfgmres_init`. Advanced users can skip this step and set the values in the *ipar* and *dpar* arrays directly.

> **WARNING**
> You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dfgmres_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

n	`INTEGER`. Sets the size of the problem.
x	`DOUBLE PRECISION`. Array of size *n*. Contains the initial approximation to the solution vector. Normally it is equal to 0 or to *b*.
b	`DOUBLE PRECISION`. Array of size *n*. Contains the right-hand side vector.

Output Parameters

RCI_request	`INTEGER`. Gives information about the result of the routine.
ipar	`INTEGER`. Array of size `128`. Refer to the FGMRES Common Parameters.
dpar	`DOUBLE PRECISION`. Array of size `128`. Refer to the FGMRES Common Parameters.
tmp	`DOUBLE PRECISION`. Array of size `((2*`*ipar*`(15) + 1)*`*n* `+` *ipar*`(15)*(`*ipar*`(15) + 9)/2 + 1)`. Refer to the FGMRES Common Parameters.

Return Values

RCI_request= 0	Indicates that the task completed normally.
RCI_request= -10000	Indicates failure to complete the task.

dfgmres_check

Checks consistency and correctness of the user defined data.

Syntax

`dfgmres_check(`*n*`, `*x*`, `*b*`, `*RCI_request*`, `*ipar*`, `*dpar*`, `*tmp*`)`

Include Files

- Fortran: `mkl_rci.fi`, `mkl_rci.f90`

Description

The routine dfgmres_check checks consistency and correctness of the parameters to be passed to the solver routine dfgmres. However, this operation does not guarantee that the method gives the correct result. It only reduces the chance of making a mistake in the parameters of the routine. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors are assumed to have been defined in a previous call to the dfgmres_init routine.

In particular, the routine checks the consistency of *ipar*(16)-*ipar*(21) and *ipar*(1), *ipar*(15). If the values do not agree, the routine emits a warning and modifies *ipar*(16)-*ipar*(21) to comply with the values of *ipar*(1), *ipar*(15). A possible use case for this modification is a non-default value (not the one set by a possible call to dfgmres_init) of *ipar*(15).

Also, if none of the stopping criteria (*ipar*(8)-*ipar*(10)) has been enabled, both *ipar*(8) and *ipar*(9) will be set to 1.

NOTE: It is not strictly necessary to call the dfgmres_check routine unless the values of *ipar*(15) or *ipar*(1) are changed after the last call to dfgmres_init.

Input Parameters

ipar	Array of size 128. Refer to the FGMRES Common Parameters.
n	INTEGER. Sets the size of the problem.
x	DOUBLE PRECISION. Array of size *n*. Contains the initial approximation to the solution vector. Normally it is equal to 0 or to *b*.
b	DOUBLE PRECISION. Array of size *n*. Contains the right-hand side vector.

Output Parameters

RCI_request	INTEGER. Gives information about result of the routine.
ipar	INTEGER. Array of size *128*. Refer to the FGMRES Common Parameters. Only *ipar*(8)-*ipar*(9) and *ipar*(16)-*ipar*(21) might be changed.
dpar	DOUBLE PRECISION. Array of size *128*. Refer to the FGMRES Common Parameters.
tmp	DOUBLE PRECISION. Array of size ((2**ipar*(15) + 1)**n* + *ipar*(15)*(*ipar*(15) + 9)/2 + 1). Refer to the FGMRES Common Parameters.

Return Values

RCI_request= 0	Indicates that the task completed normally.
RCI_request= -1100	Indicates that the task is interrupted and the errors occur.
RCI_request= -1001	Indicates that there are some warning messages.
RCI_request= -1010	Indicates that the routine changed some parameters to make them consistent or correct.
RCI_request= -1011	Indicates that there are some warning messages and that the routine changed some parameters.

dfgmres

Makes the FGMRES iterations.

Syntax

`dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)`

Include Files

- Fortran: `mkl_rci.fi`, `mkl_rci.f90`

Description

The routine `dfgmres` performs the FGMRES iterations [Saad03], using the value that was in the array `x` before the first call as an initial approximation of the solution vector. To update the current approximation to the solution, the `dfgmres_get` routine must be called. The RCI FGMRES iterations can be continued after the call to the `dfgmres_get` routine only if the value of the parameter `ipar(13)` is not equal to 0 (default value). Note that the updated solution overwrites the right-hand side in the vector *b* if the parameter `ipar(13)` is positive, and the restarted version of the FGMRES method can not be run. If you want to keep the right-hand side, you must be save it in a different memory location before the first call to the `dfgmres_get` routine with a positive `ipar(13)`.

The parameter `RCI_request` gives information about the task completion and requests results of certain operations that the solver requires.

The lengths of all the vectors must be defined in a previous call to the `dfgmres_init` routine.

Input Parameters

`n`	`INTEGER`. Sets the size of the problem.
`x`	`DOUBLE PRECISION`. Array of size *n*. Contains the initial approximation to the solution vector.
`b`	`DOUBLE PRECISION`. Array of size *n*. Contains the right-hand side vector.
`tmp`	`DOUBLE PRECISION`. Array of size `(13)`. Refer to the FGMRES Common Parameters.

Output Parameters

`RCI_request`	`INTEGER`. Informs about result of work of the routine.
`ipar`	`INTEGER`. Array of size `128`. Refer to the FGMRES Common Parameters.
`dpar`	`DOUBLE PRECISION`. Array of size `128`. Refer to the FGMRES Common Parameters.
`tmp`	`DOUBLE PRECISION`. Array of size `((2*ipar(15)+1)*n +ipar(15)*ipar(15)+9)/2 + 1`. Refer to the FGMRES Common Parameters.

Return Values

RCI_request=0	Indicates that the task completed normally and the solution is found and stored in the vector *x*. This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the *RCI_request*= 2 or 4.
RCI_request=-1	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.
RCI_request= -10	Indicates that the routine was interrupted because of an attempt to divide by zero. Usually this happens if the matrix is degenerate or almost degenerate. However, it may happen if the parameter *dpar* is altered, or if the method is not stopped when the solution is found.
RCI_request= -11	Indicates that the routine was interrupted because it entered an infinite cycle. Usually this happens because the values *ipar*(8), *ipar*(9), *ipar*(10) were altered outside of the routine, or the dfgmres_check routine was not called.
RCI_request= -12	Indicates that the routine was interrupted because errors were found in the method parameters. Usually this happens if the parameters *ipar* and *dpar* were altered by mistake outside the routine.
RCI_request= 1	Indicates that you must multiply the matrix by *tmp*(*ipar*(22)), put the result in the *tmp*(*ipar*(23)), and return control back to the routine dfgmres.
RCI_request= 2	Indicates that you must perform the stopping tests. If they fail, return control to the dfgmres routine. Otherwise, the FGMRES solution is found, and you can run the fgmres_get routine to update the computed solution in the vector *x*.
RCI_request= 3	Indicates that you must apply the inverse preconditioner to *ipar*(22), put the result in the *ipar*(23), and return control back to the routine dfgmres.
RCI_request= 4	Indicates that you must check the norm of the currently generated vector. If it is not zero within the computational/ rounding errors, return control to the dfgmres routine. Otherwise, the FGMRES solution is found, and you can run the dfgmres_get routine to update the computed solution in the vector *x*.

dfgmres_get

Retrieves the number of the current iteration and updates the solution.

Syntax

`dfgmres_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)`

Include Files

- Fortran: `mkl_rci.fi`, `mkl_rci.f90`

Description

The routine `dfgmres_get` retrieves the current iteration number of the solution process and updates the solution according to the computations performed by the `dfgmres` routine. To retrieve the current iteration number only, set the parameter `ipar(13)` = -1 beforehand. Normally, you should do this before proceeding further with the computations. If the intermediate solution is needed, the method parameters must be set properly. For details see FGMRES Common Parametersand the Iterative Sparse Solver code examples in the Intel® oneAPI Math Kernel Library (oneMKL) installation directory:

- `examples/solverf/source`

Input Parameters

n	`INTEGER`. Sets the size of the problem.
ipar	`INTEGER`. Array of size *128*. Refer to the FGMRES Common Parameters.
dpar	`DOUBLE PRECISION`. Array of size *128*. Refer to the FGMRES Common Parameters.
tmp	`DOUBLE PRECISION`. Array of size `((2*ipar(15)+1)*n +ipar(15)*ipar(15)+9)/2 + 1)`. Refer to the FGMRES Common Parameters.

Output Parameters

x	`DOUBLE PRECISION`. Array of size *n*. If `ipar(13)` = 0, it contains the updated approximation to the solution according to the computations done in `dfgmres` routine. Otherwise, it is not changed.
b	`DOUBLE PRECISION`. Array of size *n*. If `ipar(13)` > 0, it contains the updated approximation to the solution according to the computations done in `dfgmres` routine. Otherwise, it is not changed.
RCI_request	`INTEGER`. Gives information about result of the routine.
itercount	`INTEGER`. Contains the value of the current iteration number.

Return Values

RCI_request = 0	Indicates that the task completed normally.
RCI_request = -12	Indicates that the routine was interrupted because errors were found in the routine parameters. Usually this happens if the parameters *ipar* and *dpar* were altered by mistake outside of the routine.
RCI_request = -10000	Indicates that the routine failed to complete the task.

RCI ISS Implementation Details

Several aspects of the Intel® oneAPI Math Kernel Library (oneMKL) RCI ISS interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, include one of the Intel® oneAPI Math Kernel Library (oneMKL) RCI ISS language-specific header files.

NOTE
Intel® oneAPI Math Kernel Library (oneMKL) does not support the RCI ISS interface unless you include the language-specific header file.

Preconditioners based on Incomplete LU Factorization Technique

Preconditioners, or accelerators are used to accelerate an iterative solution process. In some cases, their use can reduce the number of iterations dramatically and thus lead to better solver performance. Although the terms *preconditioner* and *accelerator* are synonyms, hereafter only *preconditioner* is used.

Intel® oneAPI Math Kernel Library (oneMKL) provides two preconditioners, ILU0 and ILUT, for sparse matrices presented in the format accepted in the Intel® oneAPI Math Kernel Library (oneMKL) direct sparse solvers (three-array variation of the CSR storage format described inSparse Matrix Storage Format). The algorithms used are described in [Saad03].

The ILU0 preconditioner is based on a well-known factorization of the original matrix into a product of two triangular matrices: lower and upper triangular matrices. Usually, such decomposition leads to some fill-in in the resulting matrix structure in comparison with the original matrix. The distinctive feature of the ILU0 preconditioner is that it preserves the structure of the original matrix in the result.

Unlike the ILU0 preconditioner, the ILUT preconditioner preserves some resulting fill-in in the preconditioner matrix structure. The distinctive feature of the ILUT algorithm is that it calculates each element of the preconditioner and saves each one if it satisfies two conditions simultaneously: its value is greater than the product of the given tolerance and matrix row norm, and its value is in the given bandwidth of the resulting preconditioner matrix.

Both ILU0 and ILUT preconditioners can apply to any non-degenerate matrix. They can be used alone or together with the Intel® oneAPI Math Kernel Library (oneMKL) RCI FGMRES solver (seeSparse Solver Routines). Avoid using these preconditioners with MKL RCI CG solver because in general, they produce a non-symmetric resulting matrix even if the original matrix is symmetric. Usually, an inverse of the preconditioner is required in this case. To do this the Intel® oneAPI Math Kernel Library (oneMKL) triangular solver routine`mkl_dcsrtrsv` must be applied twice: for the lower triangular part of the preconditioner, and then for its upper triangular part.

NOTE
Although ILU0 and ILUT preconditioners apply to any non-degenerate matrix, in some cases the algorithm may fail to ensure successful termination and the required result. Whether or not the preconditioner produces an acceptable result can only be determined in practice.

A preconditioner may increase the number of iterations for an arbitrary case of the system and the initial solution, and even ruin the convergence. It is your responsibility as a user to choose a suitable preconditioner.

General Scheme of Using ILUT and RCI FGMRES Routines

The general scheme for use is the same for both preconditioners. Some differences exist in the calling parameters of the preconditioners and in the subsequent call of two triangular solvers. You can see all these differences in the preconditioner code examples (`dcsrilu*.*`) in the `examples`folder of the Intel® oneAPI Math Kernel Library (oneMKL) installation directory:

- examples/solverf/source

The following pseudocode shows the general scheme of using the ILUT preconditioner in the RCI FGMRES context.

```
...
generate matrix A
generate preconditioner C (optional)
  call dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)
   change parameters in ipar, dpar if necessary
   call dcsrilut(n, a, ia, ja, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar, ierr)
   call dfgmres_check(n, x, b, RCI_request, ipar, dpar, tmp)
1  call dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)
   if (RCI_request.eq.1) then
     multiply the matrix A by tmp(ipar(22)) and put the result in tmp(ipar(23))
c  proceed with FGMRES iterations
    goto 1
   endif
   if (RCI_request.eq.2) then
     do the stopping test
     if (test not passed) then
c proceed with FGMRES iterations
      go to 1
     else
c  stop FGMRES iterations.
      goto 2
     endif
   endif
   if (RCI_request.eq.3) then
c   Below, trvec is an intermediate vector of length at least n
c   Here is the recommended use of the result produced by the ILUT routine.
c   via standard Intel® oneAPI Math Kernel Library (oneMKL) Sparse Blas solver routinemkl_dcsrtrsv.
   call mkl_dcsrtrsv('L','N','U', n, bilut, ibilut, jbilut, tmp(ipar(22)),trvec)
   call mkl_dcsrtrsv('U','N','N', n, bilut, ibilut, jbilut, trvec, tmp(ipar(23)))
c proceed with FGMRES iterations
    goto 1
   endif
   if (RCI_request.eq.4) then
   check the norm of the next orthogonal vector, it is contained in dpar(7)
```

```
    if (the norm is not zero up to rounding/computational errors) then
c  proceed with FGMRES iterations
     goto 1
    else
c  stop FGMRES iterations
     goto 2
    endif
   endif
```

2 call `dfgmres_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)`

current iteration number is in *itercount*

the computed approximation is in the array *x*

ILU0 and ILUT Preconditioners Interface Description

The concepts required to understand the use of the Intel® oneAPI Math Kernel Library (oneMKL) preconditioner routines are discussed in theAppendix A Linear Solvers Basics.

In this section FORTRAN style notations are used. All types refer to the standard Fortran types, `INTEGER`, and `DOUBLE PRECISION`.

User Data Arrays

The preconditioner routines take arrays of user data as input. To minimize storage requirements and improve overall run-time efficiency, the Intel® oneAPI Math Kernel Library (oneMKL) preconditioner routines do not make copies of the user input arrays.

Common Parameters

Some parameters of the preconditioners are common with the FGMRES Common Parameters. The routine `dfgmres_init` specifies their default and initial values. However, some parameters can be redefined with other values. These parameters are listed below.

For the ILU0 preconditioner:

ipar`(2)` - specifies the destination of error messages generated by the ILU0 routine. The default value 6 means that all error messages are displayed on the screen. Otherwise routine creates a log file called `MKL_PREC_log.txt` and writes error messages to it. Note if the parameter *ipar*`(6)` is set to 0, then error messages are not generated at all.

ipar`(6)` - specifies whether error messages are generated. If its value is not equal to 0, the ILU0 routine returns error messages as specified by the parameter *ipar*`(2)`. Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter *ierr*. The default value is 1.

For the ILUT preconditioner:

ipar`(2)` - specifies the destination of error messages generated by the ILUT routine. The default value 6 means that all messages are displayed on the screen. Otherwise routine creates a log file called `MKL_PREC_log.txt` and writes error messages to it. Note if the parameter *ipar*`(6)` is set to 0, then error messages are not generated at all.

ipar`(6)` - specifies whether error messages are generated. If its value is not equal to 0, the ILUT routine returns error messages as specified by the parameter *ipar*`(2)`. Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter *ierr*. The default value is 1.

ipar(7) - if its value is greater than 0, the ILUT routine generates warning messages as specified by the parameter *ipar*(2) and continues calculations. If its value is equal to 0, the routine returns a positive value of the parameter *ierr*. If its value is less than 0, the routine generates a warning message as specified by the parameter *ipar*(2) and returns a positive value of the parameter *ierr*. The default value is 1.

dcsrilu0

ILU0 preconditioner based on incomplete LU factorization of a sparse matrix.

Syntax

```
call dcsrilu0(n, a, ia, ja, bilu0, ipar, dpar, ierr)
```

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The routine dcsrilu0 computes a preconditioner *B* [Saad03] of a given sparse matrix *A* stored in the format accepted in the direct sparse solvers:

*A~B=L*U* , where *L* is a lower triangular matrix with a unit diagonal, *U* is an upper triangular matrix with a non-unit diagonal, and the portrait of the original matrix *A* is used to store the incomplete factors *L* and *U*.

Caution
This routine supports only one-based indexing of the array parameters.

Input Parameters

n — INTEGER. Size (number of rows or columns) of the original square *n*-by-*n* matrix *A*.

a — DOUBLE PRECISION. Array containing the set of elements of the matrix *A*. Its length is equal to the number of non-zero elements in the matrix *A*. Refer to the *values* array description in the Sparse Matrix Storage Format for more details.

ia — INTEGER. Array of size (*n*+1) containing begin indices of rows of the matrix *A* such that *ia*(i) is the index in the array *a* of the first non-zero element from the row i. The value of the last element *ia*(*n*+1) is equal to the number of non-zero elements in the matrix *A*, plus one. Refer to the *rowIndex* array description in the Sparse Matrix Storage Format for more details.

ja — INTEGER. Array containing the column indices for each non-zero element of the matrix *A*. It is important that the indices are in increasing order per row. The matrix size is equal to the size of the array *a*. Refer to the *columns* array description in the Sparse Matrix Storage Format for more details.

Caution
If column indices are not stored in ascending order for each row of matrix, the result of the routine might not be correct.

ipar

INTEGER. Array of size *128*. This parameter specifies the integer set of data for both the ILU0 and RCI FGMRES computations. Refer to the *ipar* array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries that are specific to ILU0 are listed below.

ipar(31) specifies how the routine operates when a zero diagonal element occurs during calculation. If this parameter is set to 0 (the default value set by the routine dfgmres_init), then the calculations are stopped and the routine returns a non-zero error value. Otherwise, the diagonal element is set to the value of *dpar*(32) and the calculations continue.

NOTE
You can declare the *ipar* array with a size of 32. However, for future compatibility you must declare the array *ipar* with length 128.

dpar

DOUBLE PRECISION. Array of size *128*. This parameter specifies the double precision set of data for both the ILU0 and RCI FGMRES computations. Refer to the *dpar* array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries specific to ILU0 are listed below.

dpar(31) specifies a small value, which is compared with the computed diagonal elements. When *ipar*(31) is not 0, then diagonal elements less than *dpar*(31) are set to *dpar*(32). The default value is 1.0e-16.

NOTE
This parameter can be set to the negative value, because the calculation uses its absolute value.

If this parameter is set to 0, the comparison with the diagonal element is not performed.

dpar(32) specifies the value that is assigned to the diagonal element if its value is less than *dpar*(31) (see above). The default value is 1.0e-10.

NOTE
You can declare the *dpar* array with a size of 32. However, for future compatibility you must declare the array *dpar* with length 128.

Output Parameters

bilu0 DOUBLE PRECISION. Array *B* containing non-zero elements of the resulting preconditioning matrix *B*, stored in the format accepted in direct sparse solvers. Its size is equal to the number of non-zero elements in the matrix *A*. Refer to the *values* array description in the Sparse Matrix Storage Format section for more details.

ierr INTEGER. Error flag, gives information about the routine completion.

NOTE
To present the resulting preconditioning matrix in the CSR3 format the arrays *ia* (row indices) and *ja* (column indices) of the input matrix must be used.

Return Values

ierr=0 Indicates that the task completed normally.

ierr=-101 Indicates that the routine was interrupted and that error occurred: at least one diagonal element is omitted from the matrix in CSR3 format (see Sparse Matrix Storage Format).

ierr=-102 Indicates that the routine was interrupted because the matrix contains a diagonal element with the value of zero.

ierr=-103 Indicates that the routine was interrupted because the matrix contains a diagonal element which is so small that it could cause an overflow, or that it would cause a bad approximation to ILU0.

ierr=-104 Indicates that the routine was interrupted because the memory is insufficient for the internal work array.

ierr=-105 Indicates that the routine was interrupted because the input matrix size *n* is less than or equal to 0.

ierr=-106 Indicates that the routine was interrupted because the column indices *ja* are not in the ascending order.

Interfaces

FORTRAN 77 and Fortran 95:

```
SUBROUTINE dcsrilu0 (n, a, ia, ja, bilu0, ipar, dpar, ierr)
INTEGER n, ierr, ipar(128)
INTEGER ia(*), ja(*)
DOUBLE PRECISION a(*), bilu0(*), dpar(128)
```

dcsrilut

ILUT preconditioner based on the incomplete LU factorization with a threshold of a sparse matrix.

Syntax

`call dcsrilut(n, a, ia, ja, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar, ierr)`

Include Files

- Fortran: `mkl_rci.fi`, `mkl_rci.f90`

Description

The routine `dcsrilut` computes a preconditioner *B* [Saad03] of a given sparse matrix *A* stored in the format accepted in the direct sparse solvers:

*A~B=L*U* , where *L* is a lower triangular matrix with unit diagonal and *U* is an upper triangular matrix with non-unit diagonal.

The following threshold criteria are used to generate the incomplete factors *L* and *U*:

1) the resulting entry must be greater than the matrix current row norm multiplied by the parameter *tol*, and

2) the number of the non-zero elements in each row of the resulting *L* and *U* factors must not be greater than the value of the parameter *maxfil*.

> **Caution**
> This routine supports only one-based indexing of the array parameters.

Input Parameters

n

`INTEGER`. Size (number of rows or columns) of the original square *n*-by-*n* matrix *A*.

a

`DOUBLE PRECISION`. Array containing all non-zero elements of the matrix *A*. The length of the array is equal to their number. Refer to *values* array description in the Sparse Matrix Storage Format section for more details.

ia

`INTEGER`. Array of size `(n+1)` containing indices of non-zero elements in the array *a*. *ia*`(i)` is the index of the first non-zero element from the row *i*. The value of the last element *ia*`(n+1)` is equal to the number of non-zeros in the matrix *A*, plus one. Refer to the *rowIndex* array description in the Sparse Matrix Storage Format for more details.

ja

`INTEGER`. Array of size equal to the size of the array *a*. This array contains the column numbers for each non-zero element of the matrix *A*. It is important that the indices are in increasing order per row. Refer to the *columns* array description in the Sparse Matrix Storage Format for more details.

> **Caution**
> If column indices are not stored in ascending order for each row of matrix, the result of the routine might not be correct.

tol DOUBLE PRECISION. Tolerance for threshold criterion for the resulting entries of the preconditioner.

maxfil INTEGER. Maximum fill-in, which is half of the preconditioner bandwidth. The number of non-zero elements in the rows of the preconditioner cannot exceed (2*maxfil+1).

ipar INTEGER. Array of size *128*. This parameter is used to specify the integer set of data for both the ILUT and RCI FGMRES computations. Refer to the *ipar* array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries specific to ILUT are listed below.

ipar(31) specifies how the routine operates if the value of the computed diagonal element is less than the current matrix row norm multiplied by the value of the parameter *tol*. If *ipar*(31) = 0, then the calculation is stopped and the routine returns non-zero error value. Otherwise, the value of the diagonal element is set to a value determined by *dpar*(31) (see its description below), and the calculations continue.

NOTE
There is no default value for *ipar*(31) even if the preconditioner is used within the RCI ISS context. Always set the value of this entry.

NOTE
You must declare the array *ipar* with length 128. While defining the array in the code as INTEGER*ipar*(31) works, there is no guarantee of future compatibility with Intel® oneAPI Math Kernel Library (oneMKL).

dpar DOUBLE PRECISION. Array of size *128*. This parameter specifies the double precision set of data for both ILUT and RCI FGMRES computations. Refer to the *dpar* array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries that are specific to ILUT are listed below.

dpar(31) used to adjust the value of small diagonal elements. Diagonal elements with a value less than the current matrix row norm multiplied by *tol* are replaced with the value of *dpar*(31) multiplied by the matrix row norm.

NOTE
There is no default value for *dpar*(31) entry even if the preconditioner is used within RCI ISS context. Always set the value of this entry.

NOTE
You must declare the array *dpar* with length 128. While defining the array in the code as DOUBLE PRECISION*ipar*(31) works, there is no guarantee of future compatibility with Intel® oneAPI Math Kernel Library (oneMKL).

Output Parameters

bilut DOUBLE PRECISION. Array containing non-zero elements of the resulting preconditioning matrix *B*, stored in the format accepted in the direct sparse solvers. Refer to the *values* array description in the Sparse Matrix Storage Format for more details. The size of the array is equal to (2**maxfil*+1)**n*-*maxfil**(*maxfil*+1)+1.

NOTE
Provide enough memory for this array before calling the routine. Otherwise, the routine may fail to complete successfully with a correct result.

ibilut INTEGER. Array of size (*n*+1) containing indices of non-zero elements in the array *bilut*. *ibilut*(i) is the index of the first non-zero element from the row *i*. The value of the last element *ibilut*(*n*+1) is equal to the number of non-zeros in the matrix *B*, plus one. Refer to the *rowIndex* array description in the Sparse Matrix Storage Format for more details.

jbilut INTEGER. Array, its size is equal to the size of the array *bilut*. This array contains the column numbers for each non-zero element of the matrix *B*. Refer to the *columns* array description in the Sparse Matrix Storage Format for more details.

ierr INTEGER. Error flag, gives information about the routine completion.

Return Values

ierr=0 Indicates that the task completed normally.

ierr=-101 Indicates that the routine was interrupted because of an error: the number of elements in some matrix row specified in the sparse format is equal to or less than 0.

ierr=-102	Indicates that the routine was interrupted because the value of the computed diagonal element is less than the product of the given tolerance and the current matrix row norm, and it cannot be replaced as *ipar*(31)=0.
ierr=-103	Indicates that the routine was interrupted because the element *ia*(i + 1) is less than or equal to the element *ia*(i) (see Sparse Matrix Storage Format).
ierr=-104	Indicates that the routine was interrupted because the memory is insufficient for the internal work arrays.
ierr=-105	Indicates that the routine was interrupted because the input value of *maxfil* is less than 0.
ierr=-106	Indicates that the routine was interrupted because the size *n* of the input matrix is less than 0.
ierr=-107	Indicates that the routine was interrupted because an element of the array *ja* is less than 1, or greater than *n* (see Sparse Matrix Storage Format).
ierr=101	The value of *maxfil* is greater than or equal to *n*. The calculation is performed with the value of *maxfil* set to (*n*-1).
ierr=102	The value of *tol* is less than 0. The calculation is performed with the value of the parameter set to (-*tol*)
ierr=103	The absolute value of *tol* is greater than value of *dpar*(31); it can result in instability of the calculation.
ierr=104	The value of *dpar*(31) is equal to 0. It can cause calculations to fail.

Interfaces

FORTRAN 77 and Fortran 95:

```
SUBROUTINE dcsrilut (n, a, ia, ja, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar, ierr)
INTEGER n, ierr, ipar(*), maxfil
INTEGER ia(*), ja(*), ibilut(*), jbilut(*)
DOUBLE PRECISION a(*), bilut(*), dpar(*), tol
```

Sparse Matrix Checker Routines

Intel® oneAPI Math Kernel Library (oneMKL) provides a sparse matrix checker so that you can find errors in the storage of sparse matrices before calling Intel® oneAPI Math Kernel Library (oneMKL) PARDISO, DSS, or Sparse BLAS routines.

sparse_matrix_checker

Checks the correctness of a sparse matrix.

Syntax

error = sparse_matrix_checker (*handle*)

Include Files

- mkl_sparse_handle.fi, mkl_sparse_handle.f90

Description

The sparse_matrix_checker routine checks a user-defined array used to store a sparse matrix in order to detect issues which could cause problems in routines that require sparse input matrices, such as Intel® oneAPI Math Kernel Library (oneMKL) PARDISO, DSS, or Sparse BLAS.

Input Parameters

handle

TYPE (SPARSE_STRUCT), INTENT(INOUT)

Pointer to the data structure describing the sparse array to check.

Return Values

The routine returns a value *error*. Additionally, the *check_result* parameter returns information about where the error occurred, which can be used when *message_level* is MKL_NO_PRINT.

Sparse Matrix Checker Error Values

error value	Meaning	Location
MKL_SPARSE_CHECKER_SUCCESS	The input array successfully passed all checks.	
MKL_SPARSE_CHECKER_NON_MONOTONIC	The input array is not 0 or 1 based (*ia*(1), is not 0 or 1) or elements of *ia* are not in non-decreasing order as required.	**Fortran:** *ia*(*i* + 1) and *ia*(*i* + 2) are incompatible. *check_result*(1) = *i* *check_result*(2) = *ia*(*i* + 1) *check_result*(3) = *ia*(*i* + 2)
MKL_SPARSE_CHECKER_OUT_OF_RANGE	The value of the *ja* array is lower than the number of the first column or greater than the number of the last column.	**Fortran:** *ia*(*i* + 1) and *ia*(*i* + 2) are incompatible. *check_result*(1) = *i* *check_result*(2) = *ia*(*i* + 1) *check_result*(3) = *ia*(*i* + 2)
MKL_SPARSE_CHECKER_NONTRIANGULAR	The *matrix_structure* parameter is MKL_UPPER_TRIANGULAR and both *ia* and *ja* are not upper triangular, or the *matrix_structure* parameter is MKL_LOWER_TRIANGULAR and both *ia* and *ja* are not lower triangular	**Fortran:** *ia*(*i* + 1) and *ja*(*j* + 1) are incompatible. *check_result*(1) = *i* *check_result*(2) = *ia*(*i* + 1) = *j* *check_result*(3) = *ja*(*j* + 1)

error value	Meaning	Location
MKL_SPARSE_CHECKER_NON ORDERED	The elements of the *ja* array are not in non-decreasing order in each row as required.	**Fortran:** *ja*(*j* + 1) and *ja*(*j* + 2) are incompatible. *check_result*(1) = *j* *check_result*(2) = *ja*(*j* + 1) *check_result*(3) = *ja*(*j* + 2)

sparse_matrix_checker_init

Initializes handle for sparse matrix checker.

Syntax

```
call sparse_matrix_checker_init (handle)
```

Include Files

- mkl_sparse_handle.fi, mkl_sparse_handle.f90

Description

The sparse_matrix_checker_init routine initializes the handle for the sparse_matrix_checker routine. The *handle* variable contains this data:

Description of sparse_matrix_checker*handle* Data

Field	Type	Possible Values	Meaning
n	INTEGER		Order of the matrix stored in sparse array.
csr_ia	INTEGER (C_INTPTR_T)	Pointer to *ia* array for matrix_format = MKL_CSR	
csr_ja	INTEGER (C_INTPTR_T)	Pointer to *ja* array for matrix_format = MKL_CSR	
check_result(3)	INTEGER (KIND=4)	See Sparse Matrix Checker Error Values for a description of the values returned in *check_result*.	Indicates location of problem in array when message_level = MKL_NO_PRINT.
indexing	INTEGER (KIND=4)	MKL_ZERO_BASED MKL_ONE_BASED	Indexing style used in array.

Field	Type	Possible Values	Meaning
matrix_structure	INTEGER (KIND=4)	MKL_GENERAL_STRUCTURE MKL_UPPER_TRIANGULAR MKL_LOWER_TRIANGULAR MKL_STRUCTURAL_SYMMETRIC	Type of sparse matrix stored in array.
matrix_format	INTEGER (KIND=4)	MKL_CSR	Format of array used for sparse matrix storage.
message_level	INTEGER (KIND=4)	MKL_NO_PRINT MKL_PRINT	Determines whether or not feedback is provided on the screen.
print_style	INTEGER (KIND=4)	MKL_C_STYLE MKL_FORTRAN_STYLE	Determines style of messages when message_level = MKL_PRINT.

Input Parameters

handle TYPE (SPARSE_STRUCT), INTENT(INOUT)

Pointer to the data structure describing the sparse array to check.

Output Parameters

handle Pointer to the initialized data structure.

Extended Eigensolver Routines

NOTE
Intel® oneAPI Math Kernel Library (oneMKL) only supports the shared memory programming (SMP) version of the eigenvalue solver.

- The FEAST Algorithm gives a brief description of the algorithm underlying the Extended Eigensolver.
- Extended Eigensolver Functionality describes the problems that can and cannot be solved with the Extended Eigensolver and how to get the best results from the routines.
- Extended Eigensolver Interfaces gives a reference for calling Extended Eigensolver routines.
-

The FEAST Algorithm

The Extended Eigensolver functionality is a set of high-performance numerical routines for solving symmetric standard eigenvalue problems, $Ax=\lambda x$, or generalized symmetric-definite eigenvalue problems, $Ax=\lambda Bx$. It yields all the eigenvalues (λ) and eigenvectors (x) within a given search interval $[\lambda_{min}, \lambda_{max}]$. It is based on the FEAST algorithm, an innovative fast and stable numerical algorithm presented in [Polizzi09], which fundamentally differs from the traditional Krylov subspace iteration based techniques (Arnoldi and Lanczos algorithms [Bai00]) or other Davidson-Jacobi techniques [Sleijpen96]. The FEAST algorithm is inspired by the density-matrix representation and contour integration techniques in quantum mechanics.

The FEAST numerical algorithm obtains eigenpair solutions using a numerically efficient contour integration technique. The main computational tasks in the FEAST algorithm consist of solving a few independent linear systems along the contour and solving a reduced eigenvalue problem. Consider a circle centered in the middle of the search interval $[\lambda_{min}, \lambda_{max}]$. The numerical integration over the circle in the current version of FEAST is performed using N_e-point Gauss-Legendre quadrature with x_e the e-th Gauss node associated with the weight ω_e. For example, for the case $N_e = 8$:

(x_1, ω_1) = (0.183434642495649 , 0.362683783378361),
(x_2, ω_2) = (-0.183434642495649 , 0.362683783378361),
(x_3, ω_3) = (0.525532409916328 , 0.313706645877887),
(x_4, ω_4) = (-0.525532409916328 , 0.313706645877887),
(x_5, ω_5) = (0.796666477413626 , 0.222381034453374),
(x_6, ω_6) = (-0.796666477413626 , 0.222381034453374),
(x_7, ω_7) = (0.960289856497536 , 0.101228536290376), and
(x_8, ω_8) = (-0.960289856497536 , 0.101228536290376).

The figure FEAST Pseudocode shows the basic pseudocode for the FEAST algorithm for the case of real symmetric (left pane) and complex Hermitian (right pane) generalized eigenvalue problems, using N for the size of the system and M for the number of eigenvalues in the search interval (see [Polizzi09]).

NOTE
The pseudocode presents a simplified version of the actual algorithm. Refer to http://arxiv.org/abs/1302.0432 for an in-depth presentation and mathematical proof of convergence of FEAST.

FEAST Pseudocode

A: real symmetric	A: complex Hermitian
B: symmetric positive definite (SPD)	B: Hermitian positive definite (HPD)
$\Re\{x\}$: real part of x	

1. Select $M_0 > M$ random vectors $Y_{N\times M_0}$
2. Set $Q = 0$ with $Q \in \mathbb{R}^{N\times M_0}$; $r = (\lambda_{max}$ -
   For $e = 1,\ldots,N_e$
   compute $\theta_e = -(\pi / 2)(x_e - 1)$,
   compute $Z_e = (\lambda_{max} + \lambda_{min}) / 2 + r\exp$
   solve $(Z_e B - A)Q_e = Y$ to obtain $Q_e \in$
   compute $Q = Q - (\omega_e / 2)\Re\{r\exp(i\theta_e$
   End
3. Form $A_{Q_{M_0\times M_0}} = Q^T AQ$ and $B_{Q_{M_0\times M_0}} = Q^T$
   reduce value of M_0 if B_Q is not sym
   positive definite.

   and its eigenvector is X_m (the m-th column of X).
6. Check convergence for the trace of the
   eigenvalues λ_m. If iterative refinement is
   needed, compute $Y = BX$ and go back to step 2.

Extended Eigensolver Functionality

The eigenvalue problems covered are as follows:

- standard, $Ax = \lambda x$
  - A complex Hermitian
  - A real symmetric
- generalized, $Ax = \lambda Bx$
  - A complex Hermitian, B Hermitian positive definite (hpd)
  - A real symmetric and B real symmetric positive definite (spd)

The Extended Eigensolver functionality offers:

- Real/Complex and Single/Double precisions: double precision is recommended to provide better accuracy of eigenpairs.
- Reverse communication interfaces (RCI) provide maximum flexibility for specific applications. RCI are independent of matrix format and inner system solvers, so you must provide your own linear system solvers (direct or iterative) and matrix-matrix multiply routines.
- Predefined driver interfaces for dense, LAPACK banded, and sparse (CSR) formats are less flexible but are optimized and easy to use:
  - The Extended Eigensolver interfaces for dense matrices are likely to be slower than the comparable LAPACK routines because the FEAST algorithm has a higher computational cost.
  - The Extended Eigensolver interfaces for banded matrices support banded LAPACK-type storage.
  - The Extended Eigensolver sparse interfaces support compressed sparse row format and use the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver.

Parallelism in Extended Eigensolver Routines

How you achieve parallelism in Extended Eigensolver routines depends on which interface you use. Parallelism (via shared memory programming) is not *explicitly* implemented in Extended Eigensolver routines within one node: the inner linear systems are currently solved one after another.

- Using the Extended Eigensolver RCI interfaces, you can achieve parallelism by providing a threaded inner system solver and a matrix-matrix multiplication routine. When using the RCI interfaces, you are responsible for activating the threaded capabilities of your BLAS and LAPACK libraries most likely using the shell variable `OMP_NUM_THREADS`.
- Using the predefined Extended Eigensolver interfaces, parallelism can be implicitly obtained within the shared memory version of BLAS, LAPACK or Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. The shell variable`MKL_NUM_THREADS`can be used for automatically setting the number of OpenMP threads (cores) for BLAS, LAPACK, and Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

Achieving Performance With Extended Eigensolver Routines

In order to use the Extended Eigensolver Routines , you need to provide

- the search interval and the size of the subspace M_0 (overestimation of the number of eigenvalues M within a given search interval);
- the system matrix in dense, banded, or sparse CSR format if the Extended Eigensolver predefined interfaces are used, or a high-performance complex direct or iterative system solver and matrix-vector multiplication routine if RCI interfaces are used.

In return, you can expect

- fast convergence with very high accuracy when seeking up to 1000 eigenpairs (in two to four iterations using $M_0 = 1.5M$, and $N_e = 8$ or at most using $N_e = 16$ contour points);
- an extremely robust approach.

The performance of the basic FEAST algorithm depends on a trade-off between the choices of the number of Gauss quadrature points N_e, the size of the subspace M_0, and the number of outer refinement loops to reach the desired accuracy. In practice you should use $M_0 > 1.5\ M$, $N_e = 8$, and at most two refinement loops.

For better performance:

- M_0 should be much smaller than the size of the eigenvalue problem, so that the arithmetic complexity depends mainly on the inner system solver (O(*NM*) for narrow-banded or sparse systems).
- Parallel scalability performance depends on the shared memory capabilities of the of the inner system solver.
- For very large sparse and challenging systems, application users should make use of the Extended Eigensolver RCI interfaces with customized highly-efficient iterative systems solvers and preconditioners.
- For the Extended Eigensolver interfaces for banded matrices, the parallel performance scalability is limited.

Extended Eigensolver Interfaces for Eigenvalues within Interval

Extended Eigensolver Naming Conventions

There are two different types of interfaces available in the Extended Eigensolver routines:

1. The reverse communication interfaces (RCI):

```
?feast_<matrix type>_rci
```

   These interfaces are matrix free format (the interfaces are independent of the matrix data formats). You must provide matrix-vector multiply and direct/iterative linear system solvers for your own explicit or implicit data format.
2. The predefined interfaces:

```
?feast_<matrix type><type of eigenvalue problem>
```

   are predefined drivers for `?feast` reverse communication interface that act on commonly used matrix data storage (dense, banded and compressed sparse row representation), using internal matrix-vector routines and selected inner linear system solvers.

For these interfaces:

- `?` indicates the data type of matrix *A* (and matrix *B* if any) defined as follows:

`s`	real, single precision
`d`	real, double precision
`c`	complex, single precision
`z`	complex , double precision

- *<matrix type>* defined as follows:

Value of *<matrix type>*		**Matrix format**	**Inner linear system solver used by Extended Eigensolver**
`sy`	(symmetric real)	Dense	LAPACK dense solvers
`he`	(Hermitian complex)		
`sb`	(symmetric banded real)	Banded-LAPACK	Internal banded solver

Value of *<matrix type>*		Matrix format	Inner linear system solver used by Extended Eigensolver
hb	(Hermitian banded complex)	Compressed sparse row	PARDISO solver
scsr	(symmetric real)		
hcsr	(Hermitian complex)		
s	(symmetric real)	Reverse communications interfaces	User defined
h	(Hermitian complex)		

- *<type of eigenvalue problem>* is:

gv	generalized eigenvalue problem
ev	standard eigenvalue problem

For example, sfeast_scsrev is a single-precision routine with a symmetric real matrix stored in sparse compressed-row format for a standard eigenvalue problem, and zfeast_hrci is a complex double-precision routine with a Hermitian matrix using the reverse communication interface.

Note that:

- ? can be s or d if a matrix is real symmetric: *<matrix type>* is sy, sb, or scsr.
- ? can be c or z if a matrix is complex Hermitian: *<matrix type>* is he, hb, or hcsr.
- ? can be c or z if the Extended Eigensolver RCI interface is used for solving a complex Hermitian problem.
- ? can be s or d if the Extended Eigensolver RCI interface is used for solving a real symmetric problem.

feastinit

Initialize Extended Eigensolver input parameters with default values.

Syntax

```
call feastinit (fpm)
```

Include Files

- mkl.fi

Description

This routine sets all Extended Eigensolver parameters to their default values.

Output Parameters

fpm	INTEGER Array, size 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.

Extended Eigensolver Input Parameters

The input parameters for Extended Eigensolver routines are contained in an integer array named *fpm*. To call the Extended Eigensolver interfaces, this array should be initialized using the routine feastinit.

Parameter	Default	Description	
fpm(1)	0	Specifies whether Extended Eigensolver routines print runtime status.	
		fpm(1)=0	Extended Eigensolver routines do not generate runtime messages at all.
		fpm(1)=1	Extended Eigensolver routines print runtime status to the screen.
fpm(2)	8	The number of contour points N_e = 8 (see the description of FEAST algorithm). Must be one of {3,4,5,6,8,10,12,16,20,24,32,40,48}.	
fpm(3)	12	Error trace double precision stopping criteria ε ($\varepsilon = 10^{-fpm(3)}$) .	
fpm(4)	20	Maximum number of Extended Eigensolver refinement loops allowed. If no convergence is reached within *fpm*(4) refinement loops, Extended Eigensolver routines return *info*=2.	
fpm(5)	0	User initial subspace. If *fpm*(5)=0 then Extended Eigensolver routines generate initial subspace, if *fpm*(5)=1 the user supplied initial subspace is used.	
fpm(6)	0	Extended Eigensolver stopping test.	
		fpm(6)=0	Extended Eigensolvers are stopped if this residual stopping test is satisfied: • generalized eigenvalue problem: $\max_{i=1:mode} \frac{\|Ax_i - \lambda_i Bx_i\|_1}{\max(\|E_{min}\|, \|E_{max}\|)\|Bx_i\|_1} < \varepsilon$ • standard eigenvalue problem: $\max_{i=1:mode} \frac{\|Ax_i - \lambda_i x_i\|_1}{\max(\|E_{min}\|, \|E_{max}\|)\|x_i\|_1} < \varepsilon$ where *mode* is the total number of eigenvalues found in the search interval and $\varepsilon = 10^{-fpm(7)}$ for real and complex or $\varepsilon = 10^{-fpm(3)}$ for double precision and double complex.
		fpm(6)=1	Extended Eigensolvers are stopped if this trace stopping test is satisfied: $\frac{\|trace_j - trace_{j-1}\|}{\max(\|E_{min}\|, \|E_{max}\|)} < \varepsilon$, where $trace_j$ denotes the sum of all eigenvalues found in the search interval [*emin*, *emax*] at the *j*-th Extended Eigensolver iteration: $trace_j = \sum_{i=1}^{M} \lambda_i^{(j)}$.
fpm(7)	5	Error trace single precision stopping criteria ($10^{-fpm(7)}$) .	
fpm(14)	0	*fpm*(14)=0	Standard use for Extended Eigensolver routines.

Parameter	Default	Description	
		fpm(14)=1	Non-standard use for Extended Eigensolver routines: return the computed eigenvectors subspace after one single contour integration.
fpm(27)	0	Specifies whether Extended Eigensolver routines check input matrices (applies to CSR format only).	
		fpm(27)=0	Extended Eigensolver routines do not check input matrices.
		fpm(27)=1	Extended Eigensolver routines check input matrices.
fpm(28)	0	Check if matrix *B* is positive definite. Set *fpm*(28) = 1 to check if *B* is positive definite.	
fpm(30) to *fpm*(63)	-	Reserved for future use.	
fpm(64)	0	Use the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver with the user-defined PARDISO *iparm* array settings.	
		NOTE This option can only be used by Extended Eigensolver Predefined Interfaces for Sparse Matrices.	
		fpm(64)=0	Extended Eigensolver routines use the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO default *iparm* settings defined by calling the pardisoinit subroutine.
		fpm(64)=1	The values from *fpm*(65) to *fpm*(128) correspond to *iparm*(1) to *iparm*(64) respectively according to the formula *fpm*(64 + *i*) = *iparm*(*i*) for *i* = 1, 2, ..., 64.

Extended Eigensolver Output Details

Errors and warnings encountered during a run of the Extended Eigensolver routines are stored in an integer variable, *info*. If the value of the output *info* parameter is not 0, either an error or warning was encountered. The possible return values for the *info* parameter along with the error code descriptions are given in the following table.

Return Codes for info Parameter

info	Classification	Description
202	Error	Problem with size of the system *n* (*n*≤0)
201	Error	Problem with size of initial subspace *m0* (*m0*≤0 or *m0*>*n*)
200	Error	Problem with *emin*,*emax* (*emin*≥*emax*)
(100+*i*)	Error	Problem with *i*-th value of the input Extended Eigensolver parameter (*fpm*(*i*)). Only the parameters in use are checked.
4	Warning	Successful return of only the computed subspace after call with *fpm*(14) = 1

info	Classification	Description
3	Warning	Size of the subspace *m0* is too small (*m0*<*m*)
2	Warning	No Convergence (number of iteration loops > *fpm*(4))
1	Warning	No eigenvalue found in the search interval. See remark below for further details.
0	Successful exit	
-1	Error	Internal error for allocation memory.
-2	Error	Internal error of the inner system solver. Possible reasons: not enough memory for inner linear system solver or inconsistent input.
-3	Error	Internal error of the reduced eigenvalue solver Possible cause: matrix *B* may not be positive definite. It can be checked by setting *fpm*(28) = 1 before calling an Extended Eigensolver routine, or by using LAPACK routines.
-4	Error	Matrix *B* is not positive definite.
-(100+*i*)	Error	Problem with the *i*-th argument of the Extended Eigensolver interface.

In some extreme cases the return value *info*=1 may indicate that the Extended Eigensolver routine has failed to find the eigenvalues in the search interval. This situation could arise if a very large search interval is used to locate a small and isolated cluster of eigenvalues (i.e. the dimension of the search interval is many orders of magnitude larger than the number of contour points. It is then either recommended to increase the number of contour points *fpm*(2) or simply rescale more appropriately the search interval. Rescaling means the initial problem of finding all eigenvalues the search interval $[\lambda_{min},\lambda_{max}]$ for the standard eigenvalue problem $A\,x=\lambda x$ is replaced with the problem of finding all eigenvalues in the search interval $[\lambda_{min}/\,t,\,\lambda_{max}/\,t]$ for the standard eigenvalue problem $(A/t)\,x=(\lambda/t)\,x$ where t is a scaling factor.

Extended Eigensolver RCI Routines

If you do not require specific linear system solvers or matrix storage schemes, you can skip this section and go directly to Extended Eigensolver Predefined Interfaces.

Extended Eigensolver RCI Interface Description

The Extended Eigensolver RCI interfaces can be used to solve standard or generalized eigenvalue problems, and are independent of the format of the matrices. As mentioned earlier, the Extended Eigensolver algorithm is based on the contour integration techniques of the matrix resolvent $G(\sigma)= (\sigma B - A)^{-1}$ over a circle. For solving a generalized eigenvalue problem, Extended Eigensolver has to perform one or more of the following operations at each contour point denoted below by Z_e :

- Factorize the matrix $(Z_e * B - A)$
- Solve the linear system $(Z_e * B - A)X = Y$ or $(Z_e * B - A)^{H}X = Y$ with multiple right hand sides, where H means transpose conjugate
- Matrix-matrix multiply $BX = Y$ or $AX = Y$

For solving a standard eigenvalue problem, replace the matrix B with the identity matrix I.

The primary aim of RCI interfaces is to isolate these operations: the linear system solver, factorization of the matrix resolvent at each contour point, and matrix-matrix multiplication. This gives universality to RCI interfaces as they are independent of data structures and the specific implementation of the operations like matrix-vector multiplication or inner system solvers. However, this approach requires some additional effort when calling the interface. In particular, operations listed above are performed by routines that you supply on data structures that you find most appropriate for the problem at hand.

To initialize an Extended Eigensolver RCI routine, set the job indicator (*ijob*) parameter to the value -1. When the routine requires the results of an operation, it generates a special value of *ijob* to indicate the operation that needs to be performed. The routine also returns *ze*, the coordinate along the complex contour, the values of array *work* or *workc*, and the number of columns to be used. Your subroutine then must perform the operation at the given contour point *ze*, store the results in prescribed array, and return control to the Extended Eigensolver RCI routine.

The following pseudocode shows the general scheme for using the Extended Eigensolver RCI functionality for a real symmetric problem:

```
     Ijob=-1 ! initialization
    do while (ijob/=0)
       call  ?feast_srci(ijob, N, Ze, work1, work2, Aq,  Bq,
                   &fpm, epsout, loop, Emin, Emax, M0, E, lambda, q, res, info)

       select case(ijob)
       case(10) !! Factorize the complex matrix (ZeB-A)
 . . . . . . . . . . . . . . . . <<< user entry

       case(11) !! Solve the complex linear system (ZeB-A)x=work2(1:N,1:M0) result in work2
. . . . . . . . . . . . . . . . <<< user entry

       case(30) !! Perform multiplication A*q(1:N,i:j) result in work1(1:N,i:j)
                !!  where i=fpm(24) and j=fpm(24)+fpm(25)-1
. . . . . . . . . . . . . . . . <<< user entry
       case(40) !! Perform multiplication B*q(1:N,i:j) result in work1(1:N,i:j)
                !!  where i=fpm(24) and j=fpm(24)+fpm(25)-1
. . . . . . . . . . . . . . . . <<< user entry

    end select
end do
```

NOTE
The `?` option in `?feast` in the pseudocode given above should be replaced by either `s` or `d`, depending on the matrix data type of the eigenvalue system.

The next pseudocode shows the general scheme for using the Extended Eigensolver RCI functionality for a complex Hermitian problem:

```
    Ijob=-1 ! initialization
    do while (ijob/=0)
       call  ?feast_hrci(ijob, N, Ze, work1, work2, Aq,  Bq,
                   &fpm, epsout, loop, Emin, Emax, M0, E, lambda, q, res, info)

       select case(ijob)
       case(10) !! Factorize the complex matrix (ZeB-A)
 . . . . . . . . . . . . . . . . <<< user entry
       case (11)!! Solve the linear system (ZeB-A)y=work2 (1:N, 1:M0) result in work2
. . . . . . . . . . . . . . . . <<< user entry
       case (20)!! Factorize ( if needed by case (21)) the complex matrix     (ZeB-A)^H
    !!ATTENTION: This option requires additional memory storage
    !! (i.e . the resulting matrix from case (10) cannot be overwritten)
. . . . . . . . . . . . . . . . <<< user entry
       case (21) !! Solve the linear system (ZeB-A)^Hy=work2(1:N, 1:M0) result in  work2
    !!REMARK: case (20) becomes obsolete if this solve can be performed
    !! using the factorization in case (10)
. . . . . . . . . . . . . . . . <<< user entry
       case(30) !! Perform multiplication A*q(1:N,i:j) result in work1(1:N,i:j)
```

```
                !!  where i=fpm(24) and j=fpm(25)+fpm(24)-1
. . . . . . . . . . . . . . . . . <<< user entry
       case(40) !! Perform multiplication B*q(1:N,i:j) result in work1(1:N,i:j)
                !!  where i=fpm(24) and j=fpm(25)+fpm(24)-1
. . . . . . . . . . . . . . . . . <<< user entry

    end select
end do
```

NOTE
The `?` option in `?feast` in the pseudocode given above should be replaced by either `c` or `z`, depending on the matrix data type of the eigenvalue system.

If `case(20)` can be avoided, performance could be up to twice as fast, and Extended Eigensolver functionality would use half of the memory.

If an iterative solver is used along with a preconditioner, the factorization of the preconditioner could be performed with *ijob* = 10 (and *ijob* = 20 if applicable) for a given value of Z_e, and the associated iterative solve would then be performed with *ijob* = 11 (and *ijob* = 21 if applicable).

?feast_srci/?feast_hrci

Extended Eigensolver RCI interface.

Syntax

```
call sfeast_srci (ijob, n, ze, work, workc, aq, sq, fpm, epsout, loop, emin, emax, m0,
lambda, q, m, res, info)

call dfeast_srci (ijob, n, ze, work, workc, aq, sq, fpm, epsout, loop, emin, emax, m0,
lambda, q, m, res, info)

call cfeast_hrci (ijob, n, ze, work, workc, aq, sq, fpm, epsout, loop, emin, emax, m0,
lambda, q, m, res, info)

call zfeast_hrci (ijob, n, ze, work, workc, aq, sq, fpm, epsout, loop, emin, emax, m0,
lambda, q, m, res, info)
```

Include Files

- `mkl.fi`

Description

Compute eigenvalues as described in Extended Eigensolver RCI Interface Description.

Input Parameters

ijob — INTEGER

Job indicator variable. On entry, a call to `?feast_srci`/`?feast_hrci` with *ijob*=-1 initializes the eigensolver.

n

INTEGER

Sets the size of the problem. *n* > 0.

work

REAL for sfeast_srci

DOUBLE PRECISION for dfeast_srci

COMPLEX for cfeast_hrci

COMPLEX*16 for zfeast_hrci

Workspace array of size *n* by *m0*.

workc

COMPLEX for sfeast_srci and cfeast_hrci

COMPLEX*16 for dfeast_srci and zfeast_hrci

Workspace array of size *n* by *m0*.

aq, *sq*

REAL for sfeast_srci

DOUBLE PRECISION for dfeast_srci

COMPLEX for cfeast_hrci

COMPLEX*16 for zfeast_hrci

Workspace arrays of size *m0* by *m0*.

fpm

INTEGER

Array, size of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.

emin, *emax*

REAL for sfeast_srci and cfeast_hrci

DOUBLE PRECISION for dfeast_srci and zfeast_hrci

The lower and upper bounds of the interval to be searched for eigenvalues; *emin* ≤ *emax*.

NOTE Users are advised to avoid situations in which eigenvalues nearly coincide with the interval endpoints. This may lead to unpredictable selection or omission of such eigenvalues. Users should instead specify a slightly larger interval than needed and, if required, pick valid eigenvalues and their corresponding eigenvectors for subsequent use.

m0

INTEGER

On entry, specifies the initial guess for subspace size to be used, 0 < *m0*≤*n*. Set *m0* ≥ *m* where *m* is the total number of eigenvalues located in the interval [*emin*, *emax*]. If the initial guess is wrong, Extended Eigensolver routines return *info*=3.

q

REAL for sfeast_srci

DOUBLE PRECISION for dfeast_srci

COMPLEX for cfeast_hrci

COMPLEX*16 for zfeast_hrci

On entry, if *fpm*(5)=1, the array *q* of size *n* by *m* contains a basis of guess subspace where *n* is the order of the input matrix.

Output Parameters

ijob

On exit, the parameter carries the status flag that indicates the condition of the return. The status information is divided into three categories:

1. A zero value indicates successful completion of the task.
2. A positive value indicates that the solver requires a matrix-vector multiplication or solving a specific system with a complex coefficient.
3. A negative value indicates successful initiation.

A non-zero value of *ijob* specifically means the following:

- *ijob* = 10 - factorize the complex matrix Z_e*B - A at a given contour point Z_e and return the control to the ?feast_srci/?feast_hrci routine where Z_e is a complex number meaning contour point and its value is defined internally in ?feast_srci/?feast_hrci.
- *ijob* =11 - solve the complex linear system (Z_e*B - A)*y = *workc*(*n*, *m0*), put the solution in *workc*(*n*, *m0*) and return the control to the ?feast_srci/?feast_hrci routine.
- *ijob* =20 - factorize the complex matrix (Z_e*B - A)^H at a given contour point Z_e and return the control to the ?feast_srci/?feast_hrci routine where Z_e is a complex number meaning contour point and its value is defined internally in ?feast_srci/?feast_hrci.

  The symbol X^H means transpose conjugate of matrix *X*.
- *ijob* = 21 - solve the complex linear system(Z_e*B - A)^H*y = *workc*(*n*, *m0*), put the solution in *workc*(*n*, *m0*) and return the control to the ?feast_srci/?feast_hrci routine. The case *ijob*=20 becomes obsolete if the solve can be performed using the factorization computed for *ijob*=10.

  The symbol X^H mean transpose conjugate of matrix *X*.
- *ijob* = 30 - multiply matrix *A* by q(*n*, *i*:*j*), put the result in *work*(*n*, *i*:*j*), and return the control to the ?feast_srci/?feast_hrci routine.

  i is *fpm*(25), and *j* is *fpm*(24) + *fpm*(25) - 1.
- *ijob* = 40 - multiply matrix *B* by q(*n*, *i*:*j*), put the result in *work*(*n*, *i*:*j*) and return the control to the ?feast_srci/?feast_hrci routine. If a standard eigenvalue problem is solved, just return *work* = q.

  i is *fpm*(25), and *j* is *fpm*(24) + *fpm*(25) - 1.
- *ijob* = -2 - rerun the ?feast_srci/?feast_hrci task with the same parameters.

ze

COMPLEX for sfeast_srci and cfeast_hrci

COMPLEX*16 for dfeast_srci and zfeast_hrci

Defines the coordinate along the complex contour. All values of *ze* are generated by ?feast_srci/?feast_hrci internally.

fpm

On output, contains coordinates of columns of work array needed for iterative refinement. (See Extended Eigensolver RCI Interface Description.)

epsout
: REAL for sfeast_srci and cfeast_hrci

DOUBLE PRECISION for dfeast_srci and zfeast_hrci

On output, contains the relative error on the trace: $|trace_i - trace_{i-1}| / \max(|emin|, |emax|)$

loop
: INTEGER

On output, contains the number of refinement loop executed. Ignored on input.

lambda
: REAL for sfeast_srci and cfeast_hrci

DOUBLE PRECISION for dfeast_srci and zfeast_hrci

Array of length *m0*. On output, the first *m* entries of *lambda* are eigenvalues found in the interval.

q
: On output, *q* contains all eigenvectors corresponding to *lambda*.

m
: INTEGER

The total number of eigenvalues found in the interval [*emin*, *emax*]: $0 \le m \le m0$.

res
: REAL for sfeast_srci and cfeast_hrci

DOUBLE PRECISION for dfeast_srci and zfeast_hrci

Array of length *m0*. On exit, the first *m* components contain the relative residual vector:

- generalized eigenvalue problem:

$$\frac{\|Ax_i - \lambda_i Bx_i\|_1}{\max(|E_{\min}|, |E_{\max}|)\|Bx_i\|_1}$$

- standard eigenvalue problem:

$$\frac{\|Ax_i - \lambda_i x_i\|_1}{\max(|E_{\min}|, |E_{\max}|)\|x_i\|_1}$$

for $i=1, 2, \ldots, m$, and where *m* is the total number of eigenvalues found in the search interval.

info
: INTEGER

If *info*=0, the execution is successful. If *info* ≠ 0, see Output Eigensolver info Details.

Extended Eigensolver Predefined Interfaces

The predefined interfaces include routines for standard and generalized eigenvalue problems, and for dense, banded, and sparse matrices.

Matrix Type	Standard Eigenvalue Problem	Generalized Eigenvalue Problem
Dense	?feast_syev	?feast_sygv

Matrix Type	Standard Eigenvalue Problem	Generalized Eigenvalue Problem
	?feast_heev	?feast_hegv
Banded	?feast_sbev ?feast_hbev	?feast_sbgv ?feast_hbgv
Sparse	?feast_scsrev ?feast_hcsrev	?feast_scsrgv ?feast_hcsrgv

Matrix Storage

The symmetric and Hermitian matrices used in Extended Eigensolvers predefined interfaces can be stored in full, band, and sparse formats.

- In the full storage format (described in Full Storage in additional detail) you store all elements, all of the elements in the upper triangle of the matrix, or all of the elements in the lower triangle of the matrix.
- In the band storage format (described in Band storage in additional detail), you store only the elements along a diagonal band of the matrix.
- In the sparse format (described in Storage Arrays for a Matrix in CSR Format (3-Array Variation)), you store only the non-zero elements of the matrix.

In generalized eigenvalue systems you must use the same family of storage format for both matrices *A* and *B*. The bandwidth can be different for the banded format (*klb* can be different from *kla*), and the position of the non-zero elements can also be different for the sparse format (CSR coordinates *ib* and *jb* can be different from *ia* and *ja*).

?feast_syev/?feast_heev

Extended Eigensolver interface for standard eigenvalue problem with dense matrices.

Syntax

```
call sfeast_syev(uplo, n, a, lda, fpm, epsout, loop, emin, emax, m0, e, x, m, res, info)
call dfeast_syev(uplo, n, a, lda, fpm, epsout, loop, emin, emax, m0, e, x, m, res, info)
call cfeast_heev(uplo, n, a, lda, fpm, epsout, loop, emin, emax, m0, e, x, m, res, info)
call zfeast_heev(uplo, n, a, lda, fpm, epsout, loop, emin, emax, m0, e, x, m, res, info)
```

Include Files

- mkl.fi

Description

The routines compute all the eigenvalues and eigenvectors for standard eigenvalue problems, $Ax = \lambda x$, within a given search interval.

Input Parameters

uplo CHARACTER*1

Must be 'U' or 'L' or 'F' .

If *uplo* = 'U', *a* stores the upper triangular parts of *A*.

If *uplo* = 'L', *a* stores the lower triangular parts of *A*.

If *uplo*= 'F' , *a* stores the full matrix *A*.

n

INTEGER

Sets the size of the problem. *n* > 0.

a

REAL for sfeast_syev

DOUBLE PRECISION for dfeast_syev

COMPLEX for cfeast_heev

COMPLEX*16 for zfeast_heev

Array of dimension *lda* by *n*, contains either full matrix *A* or upper or lower triangular part of the matrix *A*, as specified by *uplo*

lda

INTEGER

The leading dimension of the array *a*. Must be at least max(1, *n*).

fpm

INTEGER

Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.

emin, *emax*

REAL for sfeast_syev and cfeast_heev

DOUBLE PRECISION for dfeast_syev and zfeast_heev

The lower and upper bounds of the interval to be searched for eigenvalues; *emin* ≤ *emax*.

NOTE Users are advised to avoid situations in which eigenvalues nearly coincide with the interval endpoints. This may lead to unpredictable selection or omission of such eigenvalues. Users should instead specify a slightly larger interval than needed and, if required, pick valid eigenvalues and their corresponding eigenvectors for subsequent use.

m0

INTEGER

On entry, specifies the initial guess for subspace dimension to be used, 0 < *m0*≤*n*. Set *m0* ≥ *m* where *m* is the total number of eigenvalues located in the interval [*emin*, *emax*]. If the initial guess is wrong, Extended Eigensolver routines return *info*=3.

x

REAL for sfeast_syev

DOUBLE PRECISION for dfeast_syev

COMPLEX for cfeast_heev

COMPLEX*16 for zfeast_heev

On entry, if *fpm*(5) =1, the array *x*(*n*, *m*) contains a basis of guess subspace where *n* is the order of the input matrix.

Output Parameters

epsout

REAL for sfeast_syev and cfeast_heev

DOUBLE PRECISION for dfeast_syev and zfeast_heev

On output, contains the relative error on the trace: $|trace_i - trace_{i-1}| / \max(|emin|, |emax|)$

loop

INTEGER

On output, contains the number of refinement loop executed. Ignored on input.

e

REAL for sfeast_syev and cfeast_heev

DOUBLE PRECISION for dfeast_syev and zfeast_heev

Array of length *m0*. On output, the first *m* entries of *e* are eigenvalues found in the interval.

x

On output, the first *m* columns of *x* contain the orthonormal eigenvectors corresponding to the computed eigenvalues *e*, with the *i*-th column of *x* holding the eigenvector associated with *e*(*i*).

m

INTEGER

The total number of eigenvalues found in the interval [*emin*, *emax*]: $0 \le m \le m0$.

res

REAL for sfeast_syev and cfeast_heev

DOUBLE PRECISION for dfeast_syev and zfeast_heev

Array of length *m0*. On exit, the first *m* components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i x_i\|_1}{\max\left(|E_{\min}|, |E_{\max}|\right)\|x_i\|_1}$$

for $i=1, 2, \ldots, m$, and where *m* is the total number of eigenvalues found in the search interval.

info

INTEGER

If *info*=0, the execution is successful. If *info* ≠ 0, see Output Eigensolver info Details.

?feast_sygv/?feast_hegv

Extended Eigensolver interface for generalized eigenvalue problem with dense matrices.

Syntax

```
call sfeast_sygv(uplo, n, a, lda, b, ldb, fpm, epsout, loop, emin, emax, m0, e, x, m, res, info)
```

```
call dfeast_sygv(uplo, n, a, lda, b, ldb, fpm, epsout, loop, emin, emax, m0, e, x, m, res, info)
```

```
call cfeast_hegv(uplo, n, a, lda, b, ldb, fpm, epsout, loop, emin, emax, m0, e, x, m,
res, info)
```

```
call zfeast_hegv(uplo, n, a, lda, b, ldb, fpm, epsout, loop, emin, emax, m0, e, x, m,
res, info)
```

Include Files

Description

The routines compute all the eigenvalues and eigenvectors for generalized eigenvalue problems, $Ax = \lambda Bx$, within a given search interval.

Input Parameters

uplo

CHARACTER*1

Must be 'U' or 'L' or 'F' .

If *UPLO* = 'U', *a* and *b* store the upper triangular parts of *A* and *B* respectively.

If *UPLO* = 'L', *a* and *b* store the lower triangular parts of *A* and *B* respectively.

If *UPLO*= 'F', *a* and *b* store the full matrices *A* and *B* respectively.

n

INTEGER

Sets the size of the problem. *n* > 0.

a

REAL for sfeast_sygv

DOUBLE PRECISION for dfeast_sygv

COMPLEX for cfeast_hegv

COMPLEX*16 for zfeast_hegv

Array of dimension *lda* by *n*, contains either full matrix *A* or upper or lower triangular part of the matrix *A*, as specified by *uplo*

lda

INTEGER

The leading dimension of the array *a*. Must be at least max(1, *n*).

b

REAL for sfeast_sygv

DOUBLE PRECISION for dfeast_sygv

COMPLEX for cfeast_hegv

COMPLEX*16 for zfeast_hegv

Array of dimension *ldb* by *n*, contains either full matrix *B* or upper or lower triangular part of the matrix *B*, as specified by *uplo*

ldb

INTEGER

The leading dimension of the array *B*. Must be at least max(1, *n*).

fpm

INTEGER

Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.

emin, *emax*

REAL for sfeast_sygv and cfeast_hegv

DOUBLE PRECISION for dfeast_sygv and zfeast_hegv

The lower and upper bounds of the interval to be searched for eigenvalues; *emin* ≤ *emax*.

> **NOTE** Users are advised to avoid situations in which eigenvalues nearly coincide with the interval endpoints. This may lead to unpredictable selection or omission of such eigenvalues. Users should instead specify a slightly larger interval than needed and, if required, pick valid eigenvalues and their corresponding eigenvectors for subsequent use.

m0

INTEGER

On entry, specifies the initial guess for subspace dimension to be used, 0 < *m0*≤*n*. Set *m0* ≥ *m* where *m* is the total number of eigenvalues located in the interval [*emin*, *emax*]. If the initial guess is wrong, Extended Eigensolver routines return *info*=3.

x

REAL for sfeast_sygv

DOUBLE PRECISION for dfeast_sygv

COMPLEX for cfeast_hegv

COMPLEX*16 for zfeast_hegv

On entry, if *fpm*(5)=1, the array *x*(*n*, *m*) contains a basis of guess subspace where *n* is the order of the input matrix.

Output Parameters

epsout

REAL for sfeast_sygv and cfeast_hegv

DOUBLE PRECISION for dfeast_sygv and zfeast_hegv

On output, contains the relative error on the trace: |$trace_i$ - $trace_{i-1}$| /max(|*emin*|, |*emax*|)

loop

INTEGER

On output, contains the number of refinement loop executed. Ignored on input.

e

REAL for sfeast_sygv and cfeast_hegv

DOUBLE PRECISION for dfeast_sygv and zfeast_hegv

Array of length *m0*. On output, the first *m* entries of *e* are eigenvalues found in the interval.

x

On output, the first *m* columns of *x* contain the orthonormal eigenvectors corresponding to the computed eigenvalues *e*, with the *i*-th column of *x* holding the eigenvector associated with *e*(*i*).

m INTEGER

The total number of eigenvalues found in the interval [*emin*, *emax*]: 0 ≤ *m* ≤ *m0*.

res REAL for sfeast_sygv and cfeast_hegv

DOUBLE PRECISION for dfeast_sygv and zfeast_hegv

Array of length *m0*. On exit, the first *m* components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i Bx_i\|_1}{\max\left(|E_{\min}|, |E_{\max}|\right)\|Bx_i\|_1}$$

for *i*=1, 2, …, *m*, and where *m* is the total number of eigenvalues found in the search interval.

info INTEGER

If *info*=0, the execution is successful. If *info* ≠ 0, see Output Eigensolver info Details.

?feast_sbev/?feast_hbev

Extended Eigensolver interface for standard eigenvalue problem with banded matrices.

Syntax

```
call sfeast_sbev(uplo, n, kla, a, lda, fpm, epsout, loop, emin, emax, m0, e, x, m, res, info)
call dfeast_sbev(uplo, n, kla, a, lda, fpm, epsout, loop, emin, emax, m0, e, x, m, res, info)

Description

The routines compute all the eigenvalues and eigenvectors for standard eigenvalue problems, $Ax = \lambda x$, within a given search interval.

Input Parameters

uplo

CHARACTER*1

Must be 'U' or 'L' or 'F' .

If *uplo* = 'U', *a* stores the upper triangular parts of *A*.

If *uplo* = 'L', *a* stores the lower triangular parts of *A*.

If *uplo*= 'F' , *a* stores the full matrix *A*.

n

INTEGER

Sets the size of the problem. *n* > 0.

a

REAL for sfeast_scsrev

DOUBLE PRECISION for dfeast_scsrev

COMPLEX for cfeast_hcsrev

COMPLEX*16 for zfeast_hcsrev

Array containing the nonzero elements of either the full matrix *A* or the upper or lower triangular part of the matrix *A*, as specified by *uplo*.

ia

INTEGER

Array of length *n* + 1, containing indices of elements in the array *a* , such that *ia(i)* is the index in the array *a* of the first non-zero element from the row *i* . The value of the last element *ia(n + 1)* is equal to the number of non-zeros plus one.

ja

INTEGER

Array containing the column indices for each non-zero element of the matrix *A* being represented in the array *a* . Its length is equal to the length of the array *a*.

fpm

INTEGER

Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.

emin, *emax*

REAL for sfeast_scsrev and cfeast_hcsrev

DOUBLE PRECISION for dfeast_scsrev and zfeast_hcsrev

The lower and upper bounds of the interval to be searched for eigenvalues; *emin* ≤ *emax*.

NOTE Users are advised to avoid situations in which eigenvalues nearly coincide with the interval endpoints. This may lead to unpredictable selection or omission of such eigenvalues. Users should instead specify a slightly larger interval than needed and, if required, pick valid eigenvalues and their corresponding eigenvectors for subsequent use.

m0

On entry, specifies the initial guess for subspace dimension to be used, 0 < *m0*≤*n*. Set *m0* ≥ *m* where *m* is the total number of eigenvalues located in the interval [*emin*, *emax*]. If the initial guess is wrong, Extended Eigensolver routines return *info*=3.

x

REAL for sfeast_scsrev

DOUBLE PRECISION for dfeast_scsrev

COMPLEX for cfeast_hcsrev

COMPLEX*16 for zfeast_hcsrev

On entry, if *fpm*(5)=1, the array *x*(*n*, *m*) contains a basis of guess subspace where *n* is the order of the input matrix.

Output Parameters

fpm

On output, the last 64 values correspond to Intel® oneAPI Math Kernel Library (oneMKL) PARDISO*iparm*(1) to *iparm*(64) (regardless of the value of *fpm*(64) on input).

epsout

REAL for sfeast_scsrev and cfeast_hcsrev

DOUBLE PRECISION for dfeast_scsrev and zfeast_hcsrev

On output, contains the relative error on the trace: |$trace_i$ - $trace_{i-1}$| /max(|*emin*|, |*emax*|)

loop

INTEGER

On output, contains the number of refinement loop executed. Ignored on input.

e

REAL for sfeast_scsrev and cfeast_hcsrev

DOUBLE PRECISION for dfeast_scsrev and zfeast_hcsrev

Array of length *m0*. On output, the first *m* entries of *e* are eigenvalues found in the interval.

x

On output, the first *m* columns of *x* contain the orthonormal eigenvectors corresponding to the computed eigenvalues *e*, with the *i*-th column of *x* holding the eigenvector associated with *e*(*i*).

m

INTEGER

The total number of eigenvalues found in the interval [*emin*, *emax*]: 0 ≤ *m* ≤ *m0*.

res — `REAL` for `sfeast_scsrev` and `cfeast_hcsrev`

`DOUBLE PRECISION` for `dfeast_scsrev` and `zfeast_hcsrev`

Array of length *m0*. On exit, the first *m* components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i x_i\|_1}{\max\left(|E_{\min}|, |E_{\max}|\right)\|x_i\|_1}$$

for *i*=1, 2, …, *m*, and where *m* is the total number of eigenvalues found in the search interval.

info — `INTEGER`

If *info*=0, the execution is successful. If *info* ≠ 0, see Output Eigensolver info Details.

?feast_scsrgv/?feast_hcsrgv

Extended Eigensolver interface for generalized eigenvalue problem with sparse matrices.

Syntax

```
call sfeast_scsrgv(uplo, n, a, ia, ja, b, ib, jb, fpm, epsout, loop, emin, emax, m0, e, x, m, res, info)
call dfeast_scsrgv(uplo, n, a, ia, ja, b, ib, jb, fpm, epsout, loop, emin, emax, m0, e, x, m, res, info)
call cfeast_hcsrgv(uplo, n, a, ia, ja, b, ib, jb, fpm, epsout, loop, emin, emax, m0, e, x, m, res, info)
call zfeast_hcsrgv(uplo, n, a, ia, ja, b, ib, jb, fpm, epsout, loop, emin, emax, m0, e, x, m, res, info)
```

Include Files

- `mkl.fi`

Description

The routines compute all the eigenvalues and eigenvectors for generalized eigenvalue problems, $Ax = \lambda Bx$, within a given search interval.

NOTE
Both matrices *A* and *B* must use the same family of storage format. The position of the non-zero elements can be different (CSR coordinates *ib* and *jb* can be different from *ia* and *ja*).

Input Parameters

uplo — `CHARACTER*1`

Must be `'U'` or `'L'` or `'F'` .

If *UPLO* = `'U'`, *a* and *b* store the upper triangular parts of *A* and *B* respectively.

If *UPLO* = 'L', *a* and *b* store the lower triangular parts of *A* and *B* respectively.

If *UPLO*= 'F', *a* and *b* store the full matrices *A* and *B* respectively.

n

INTEGER

Sets the size of the problem. *n* > 0.

a

REAL for sfeast_scsrgv

DOUBLE PRECISION for dfeast_scsrgv

COMPLEX for cfeast_hcsrgv

COMPLEX*16 for zfeast_hcsrgv

Array containing the nonzero elements of either the full matrix *A* or the upper or lower triangular part of the matrix *A*, as specified by *uplo*.

ia

INTEGER

Array of length *n* + 1, containing indices of elements in the array *a* , such that *ia*(*i*) is the index in the array *a* of the first non-zero element from the row *i* . The value of the last element *ia*(*n* + 1) is equal to the number of non-zeros plus one.

ja

INTEGER

Array containing the column indices for each non-zero element of the matrix *A* being represented in the array *a* . Its length is equal to the length of the array *a*.

b

REAL for sfeast_scsrgv

DOUBLE PRECISION for dfeast_scsrgv

COMPLEX for cfeast_hcsrgv

COMPLEX*16 for zfeast_hcsrgv

Array of dimension *ldb* by *, contains the nonzero elements of either the full matrix *B* or the upper or lower triangular part of the matrix *B*, as specified by *uplo*.

ib

INTEGER

Array of length *n* + 1, containing indices of elements in the array *b* , such that *ib*(*i*) is the index in the array *b* of the first non-zero element from the row *i* . The value of the last element *ib*(*n* + 1) is equal to the number of non-zeros plus one.

jb

INTEGER

Array containing the column indices for each non-zero element of the matrix *B* being represented in the array *b* . Its length is equal to the length of the array *b*.

fpm

INTEGER

Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.

emin, *emax*

`REAL` for `sfeast_scsrgv` and `cfeast_hcsrgv`

`DOUBLE PRECISION` for `dfeast_scsrgv` and `zfeast_hcsrgv`

The lower and upper bounds of the interval to be searched for eigenvalues; *emin* ≤ *emax*.

> **NOTE** Users are advised to avoid situations in which eigenvalues nearly coincide with the interval endpoints. This may lead to unpredictable selection or omission of such eigenvalues. Users should instead specify a slightly larger interval than needed and, if required, pick valid eigenvalues and their corresponding eigenvectors for subsequent use.

m0

`INTEGER`

On entry, specifies the initial guess for subspace dimension to be used, 0 < *m0*≤*n*. Set *m0* ≥ *m* where *m* is the total number of eigenvalues located in the interval [*emin*, *emax*]. If the initial guess is wrong, Extended Eigensolver routines return *info*=3.

x

`REAL` for `sfeast_scsrgv`

`DOUBLE PRECISION` for `dfeast_scsrgv`

`COMPLEX` for `cfeast_hcsrgv`

`COMPLEX*16` for `zfeast_hcsrgv`

On entry, if *fpm*(5)=1, the array *x*(*n*, *m*) contains a basis of guess subspace where *n* is the order of the input matrix.

Output Parameters

fpm

On output, the last 64 values correspond to Intel® oneAPI Math Kernel Library (oneMKL) PARDISO*iparm*(1) to *iparm*(64) (regardless of the value of *fpm*(64) on input).

epsout

`REAL` for `sfeast_scsrgv` and `cfeast_hcsrgv`

`DOUBLE PRECISION` for `dfeast_scsrgv` and `zfeast_hcsrgv`

On output, contains the relative error on the trace: $|trace_i - trace_{i-1}|$ /max(|*emin*|, |*emax*|)

loop

`INTEGER`

On output, contains the number of refinement loop executed. Ignored on input.

e

`REAL` for `sfeast_scsrgv` and `cfeast_hcsrgv`

`DOUBLE PRECISION` for `dfeast_scsrgv` and `zfeast_hcsrgv`

Array of length *m0*. On output, the first *m* entries of *e* are eigenvalues found in the interval.

x	On output, the first *m* columns of *x* contain the orthonormal eigenvectors corresponding to the computed eigenvalues *e*, with the *i*-th column of *x* holding the eigenvector associated with *e*(*i*).
m	INTEGER The total number of eigenvalues found in the interval [*emin*, *emax*]: 0 ≤ *m* ≤ *m0*.
res	REAL for sfeast_scsrgv and cfeast_hcsrgv DOUBLE PRECISION for dfeast_scsrgv and zfeast_hcsrgv Array of length *m0*. On exit, the first *m* components contain the relative residual vector: $\frac{\|Ax_i - \lambda_i Bx_i\|_1}{\max(\|E_{\min}\|, \|E_{\max}\|)\|Bx_i\|_1}$ for *i*=1, 2, …, *m*, and where *m* is the total number of eigenvalues found in the search interval.
info	INTEGER If *info*=0, the execution is successful. If *info* ≠ 0, see Output Eigensolver info Details.

Extended Eigensolver Interfaces for Extremal Eigenvalues/Singular Values

The topics in this section discuss Extended Eigensolver interfaces to find extremal eigenvalues as well as singular values.

Extended Eigensolver Interfaces to find largest/smallest eigenvalues

The predefined interfaces include routines for standard and generalized eigenvalue problems and sparse matrices.

Matrix Type	Standard Eigenvalue Problem	Generalized Eigenvalue Problem
Sparse	mkl_sparse_?_ev	mkl_sparse_?_gv

mkl_sparse_?_ev

Computes the largest/smallest eigenvalues and corresponding eigenvectors of a standard eigenvalue problem

Syntax

```
stat = mkl_sparse_s_ev (which, pm, A, descrA, k0, k, E, X, res);
stat = mkl_sparse_d_ev (which, pm, A, descrA, k0, k, E, X, res);
```

Include Files

- mkl_solvers_ee.f90

Description

The `mkl_sparse_?_ev` routine computes the largest/smallest eigenvalues and corresponding eigenvectors of a standard eigenvalue problem.

```
Ax = lambda x
```

where `A` is the real symmetric matrix.

Input Parameters

which — CHARACTER

Indicates eigenvalues for which to search:

- `which = 'L'` indicates the largest eigenvalues.
- `which = 'S'` indicates the smallest eigenvalues.

pm — C_INT

Array of size 128. This array is used to pass various parameters to Extended Eigensolver routines. See • Extended Eigensolver Input Parameters for Extremal Eigenvalue Problem for a complete description of the parameters and their default values.

A — SPARSE_MATRIX_T

Handle containing sparse matrix in internal data structure.

descrA — MATRIX_DESCR

Structure specifying sparse matrix properties.

sparse_matrix_type_t *type* — Specifies the type of a sparse matrix:

- `SPARSE_MATRIX_TYPE_GENERAL`

  The matrix is processed as-is.
- `SPARSE_MATRIX_TYPE_SYMMETRIC`

  The matrix is symmetric (only the requested triangle is processed).

sparse_fill_mode_t *mode* — Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

- `SPARSE_FILL_MODE_LOWER`

  The lower triangular matrix part is processed.
- `SPARSE_FILL_MODE_UPPER`

  The upper triangular matrix part is processed.

sparse_diag_type_t *diag* — Specifies the diagonal type for non-general matrices:

- `SPARSE_DIAG_NON_UNIT`

  Diagonal elements might not be equal to one.
- `SPARSE_DIAG_UNIT`

Diagonal elements are equal to one

k0 — C_INT

The desired number of the largest/smallest eigenvalues to find.

Output Parameters

k — C_INT

Number of eigenvalues found.

E — C_FLOAT for `mkl_sparse_s_ev`

C_DOUBLE for `mkl_sparse_d_ev`

Array of size *k0*. Contains k largest/smallest eigenvalues.

X — C_FLOAT for `mkl_sparse_s_ev`

C_DOUBLE for `mkl_sparse_d_ev`

Array of size *k0**Number of columns of the matrix A. Contains *k* eigenvectors.

Res — C_FLOAT for `mkl_sparse_s_ev`

C_DOUBLE for `mkl_sparse_d_ev`

Array of size *k0*. Contains *k* residuals.

Stat — INTEGER

The function returns a value indicating whether the operation was successful or not, and why.

Return Values

`SPARSE_STATUS_SUCCESS`	The operation was successful.
`SPARSE_STATUS_NOT_INITIALIZED`	The routine encountered an empty handle or matrix array.
`SPARSE_STATUS_ALLOC_FAILED`	Internal memory allocation failed.
`SPARSE_STATUS_INVALID_VALUE`	The input parameters contain an invalid value.
`SPARSE_STATUS_EXECUTION_FAILED`	Execution failed.
`SPARSE_STATUS_INTERNAL_ERROR`	An error in algorithm implementation occurred.
`SPARSE_STATUS_NOT_SUPPORTED`	The requested operation is not supported.

mkl_sparse_?_gv

Computes the largest/smallest eigenvalues and corresponding eigenvectors of a generalized eigenvalue problem

Syntax

```
stat = mkl_sparse_s_gv (which, pm, A, descrA, B, descrB, k0, k, E, X, res);
stat = mkl_sparse_d_gv (which, pm, A, descrA, B, descrB, k0, k, E, X, res);
```

Include Files

- mkl_solvers_ee.f90

Description

The mkl_sparse_?_gv routine computes the largest/smallest eigenvalues and corresponding eigenvectors of a generalized eigenvalue problem.

```
Ax = lambda Bx
```

where A is the real symmetric matrix and B is the real symmetric positive definite matrix.

Input Parameters

which

CHARACTER

Indicates eigenvalues for which to search:

- which = 'L' indicates the largest eigenvalues.
- which = 'S' indicates the smallest eigenvalues.

pm

C_INT

Array of size 128. This array is used to pass various parameters to Extended Eigensolver routines. See • Extended Eigensolver Input Parameters for Extremal Eigenvalue Problem for a complete description of the parameters and their default values.

A

SPARSE_MATRIX_T

Handle containing sparse matrix in internal data structure.

descrA

MATRIX_DESCR

Structure specifying sparse matrix properties.

sparse_matrix_type_t *type*

Specifies the type of a sparse matrix:

- SPARSE_MATRIX_TYPE_GENERAL

  The matrix is processed as-is.
- SPARSE_MATRIX_TYPE_SYMMETRIC

  The matrix is symmetric (only the requested triangle is processed).

sparse_fill_mode_t *mode*

Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

- SPARSE_FILL_MODE_LOWER

  The lower triangular matrix part is processed.
- SPARSE_FILL_MODE_UPPER

  The upper triangular matrix part is processed.

sparse_diag_type_t *diag*

Specifies the diagonal type for non-general matrices:

- SPARSE_DIAG_NON_UNIT

Diagonal elements might not be equal to one.

- SPARSE_DIAG_UNIT

  Diagonal elements are equal to one

B

SPARSE_MATRIX_T

Handle containing sparse matrix in internal data structure.

descrB

MATRIX_DESCR

Structure specifying sparse matrix properties.

sparse_matrix_type_t *type*

Specifies the type of a sparse matrix:

- SPARSE_MATRIX_TYPE_GENERAL

  The matrix is processed as-is.
- SPARSE_MATRIX_TYPE_SYMMETRIC

  The matrix is symmetric (only the requested triangle is processed).

sparse_fill_mode_t *mode*

Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

- SPARSE_FILL_MODE_LOWER

  The lower triangular matrix part is processed.
- SPARSE_FILL_MODE_UPPER

  The upper triangular matrix part is processed.

sparse_diag_type_t *diag*

Specifies the diagonal type for non-general matrices:

- SPARSE_DIAG_NON_UNIT

  Diagonal elements might not be equal to one.
- SPARSE_DIAG_UNIT

  Diagonal elements are equal to one

k0

C_INT

The desired number of the largest/smallest eigenvalues to find.

Output Parameters

k

C_INT

Number of eigenvalues found.

E

C_FLOAT for `mkl_sparse_s_gv`

C_DOUBLE for `mkl_sparse_d_gv`

Array of size *k0*. Contains *k* largest/smallest eigenvalues.

X	C_FLOAT for `mkl_sparse_s_gv` C_DOUBLE for `mkl_sparse_d_gv` Array of size *k0**Number of columns of matrix A. Contains *k* eigenvectors.
Res	C_FLOAT for `mkl_sparse_s_gv` C_DOUBLE for `mkl_sparse_d_gv` Array of size *k0*. Contains *k* residuals.
Stat	INTEGER The function returns a value indicating whether the operation was successful or not, and why.

Return Values

`SPARSE_STATUS_SUCCESS`	The operation was successful.
`SPARSE_STATUS_NOT_INITIALIZED`	The routine encountered an empty handle or matrix array.
`SPARSE_STATUS_ALLOC_FAILED`	Internal memory allocation failed.
`SPARSE_STATUS_INVALID_VALUE`	The input parameters contain an invalid value.
`SPARSE_STATUS_EXECUTION_FAILED`	Execution failed.
`SPARSE_STATUS_INTERNAL_ERROR`	An error in algorithm implementation occurred.
`SPARSE_STATUS_NOT_SUPPORTED`	The requested operation is not supported.

Extended Eigensolver Interfaces to find largest/smallest singular values

The predefined interfaces include routines to find the largest and smallest singular values and the corresponding singular vectors of sparse matrices.

Matrix Type	Standard singular value problem
Sparse	mkl_sparse_?_svd

mkl_sparse_?_svd

Computes the largest/smallest singular values of a singular-value problem

Syntax

```
stat = mkl_sparse_s_svd (whichS, whichV, pm, A, descrA, k0, k, E, XL, XR, res);
stat = mkl_sparse_d_svd (whichS, whichV, pm, A, descrA, k0, k, E, XL, XR, res);
```

Include Files

- `mkl_solvers_ee.f90`

Description

The `mkl_sparse_?_svd` routine computes the largest/smallest singular values of a singular-value problem.

`AATx = σx` or `ATAx = σx`, where A is the real rectangular matrix.

Input Parameters

whichS

CHARACTER

Indicates eigenvalues for which to search:

- `whichS = 'L'` indicates the largest eigenvalues.
- `whichS = 'S'` indicates the smallest eigenvalues.

whichV

CHARACTER

Indicates singular vectors for which to search:

- `whichV = 'R'` indicates right singular vectors.
- `whichV = 'L'` indicates left singular vectors.

pm

C_INT

Array of size 128. This array is used to pass various parameters to Extended Eigensolver routines. See • Extended Eigensolver Input Parameters for Extremal Eigenvalue Problem for a complete description of the parameters and their default values.

A

SPARSE_MATRIX_T

Handle containing sparse matrix in internal data structure.

descrA

MATRIX_DESCR

Structure specifying sparse matrix properties.

sparse_matrix_type_t *type*

Specifies the type of a sparse matrix:

- `SPARSE_MATRIX_TYPE_GENERAL`

  The matrix is processed as-is.
- `SPARSE_MATRIX_TYPE_SYMMETRIC`

  The matrix is symmetric (only the requested triangle is processed).

sparse_fill_mode_t *mode*

Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

- `SPARSE_FILL_MODE_LOWER`

  The lower triangular matrix part is processed.
- `SPARSE_FILL_MODE_UPPER`

  The upper triangular matrix part is processed.

sparse_diag_type_t *diag*

Specifies the diagonal type for non-general matrices:

- `SPARSE_DIAG_NON_UNIT`

  Diagonal elements might not be equal to one.
- `SPARSE_DIAG_UNIT`

  Diagonal elements are equal to one

k0	C_INT The desired number of the largest/smallest eigenvalues to find.

Output Parameters

k	C_INT Number of eigenvalues found.
E	C_FLOAT for `mkl_sparse_s_svd` C_DOUBLE for `mkl_sparse_d_svd` Array of size *k0*. Contains *k* largest/smallest eigenvalues.
XL	Contains *k*-corresponding left singular vectors.
XR	Contains *k*-corresponding right singular vectors.
Res	C_FLOAT for `mkl_sparse_s_svd` C_DOUBLE for `mkl_sparse_d_svd` Array that contains *k* residuals.
Stat	INTEGER The function returns a value indicating whether the operation was successful or not, and why.

Return Values

`SPARSE_STATUS_SUCCESS`	The operation was successful.
`SPARSE_STATUS_NOT_INITIALIZED`	The routine encountered an empty handle or matrix array.
`SPARSE_STATUS_ALLOC_FAILED`	Internal memory allocation failed.
`SPARSE_STATUS_INVALID_VALUE`	The input parameters contain an invalid value.
`SPARSE_STATUS_EXECUTION_FAILED`	Execution failed.
`SPARSE_STATUS_INTERNAL_ERROR`	An error in algorithm implementation occurred.
`SPARSE_STATUS_NOT_SUPPORTED`	The requested operation is not supported.

mkl_sparse_ee_init

Initializes Extended Eigensolver input parameters with default values

Syntax

```
stat = mkl_sparse_ee_init (MKL_INT* pm);
```

Include Files

- `mkl_solvers_ee.f90`

Description

This routine sets all Extended Eigensolver parameters to their default values.

Output Parameters

pm	C_INT Array of size 128. This array is used to pass various parameters to Extended Eigensolver routines. See • Extended Eigensolver Input Parameters for Extremal Eigenvalue Problem for a complete description of the parameters and their default values.

Extended Eigensolver Input Parameters for Extremal Eigenvalue Problem

The input parameters for Extended Eigensolver routines are contained in an integer array named *pm*. To call the Extended Eigensolver interfaces, initialize this array using the `mkl_sparse_ee_init` routine.

Parameter	Default	Description
pm(1)	0	Reserved for future use.
pm(2)	6	Defines the tolerance for the stopping criteria: $\in = 10^{-pm(2)+1}$
pm(3)	0	Specifies the algorithm to use: • 0 - Decided at runtime • 1 - The Krylov-Schur method • 2 - Subspace Iteration technique based on FEAST algorithm
pm(4)	*	This parameter is referenced only for Krylov-Schur Method. It indicates the number of Lanczos/Arnoldi vectors (NCV) generated at each iteration. This parameter must be less than or equal to size of matrix and greater than number of eigenvalues (k0) to be computed. If unspecified, NCV is set to be at least 1.5 times larger than k0.
pm(5)	*	Maximum number of iterations. If unspecified, this parameter is set to 10000 for the Krylov-Schur method and 60 for the subspace iteration method.
pm(6)	0	Power of Chebychev expansion for approximate spectral projector. Only referenced when *pm*(3) =1
pm(7)	1	Used only for Krylov-Schur Method. If 0, then the method only computes eigenvalues. If 1, then the method computes eigenvalues and eigenvectors. The subspace iteration method always computes eigenvectors/singular vectors. You must allocate the required memory space.
pm(8)	0	Convergence stopping criteria. Defines whether the stopping criteria for the iterations with respect to the true residuals (used if pm(9) is not zero) and residual norm estimates are relative to the eigenvalues/singular values or not. If 0, the stopping criteria with respect to the true residuals is: $\frac{\|\|Ax-\lambda x\|\|}{\|\lambda\|} < 10^{-pm(2)+1}$

Parameter	Default	Description
		or $\frac{\|\|Ax-\lambda Bx\|\|}{\|\lambda\|} < 10^{-pm(2)+1}$ If 1, the stopping criteria with respect to the true residuals is: $\left\|\left\|Ax-\lambda x\right\|\right\| < 10^{-pm(2)+1}$ or $\left\|\left\|Ax-\lambda Bx\right\|\right\| < 10^{-pm(2)+1}$ for a generalized eigenproblem. The residual norm estimates are based on the magnitude of the last eigenvector of the Schur decomposition matrix and the exact formula can be found in the literature. When `pm(8)=0`, the residual norm estimate is additionally divided by the magnitude of the computed eigenvalue and compared to $10^{(-pm(2)+1)}$.
pm(9)	0	Specifies if for detecting convergence the solver must compute the true residuals for eigenpairs for the Krylov-Schur method or it can only use the residual norm estimates. If 0, only residual norm estimates are used. If 1, the solver computes not just residual norm estimates but also the true residuals as defined in the description of pm(8).
pm(10)	0	Used only for the Krylov-Schur method and only as an output parameter. Reports the reason for exiting the iteration loop of the method: • If 0, the iterations stopped since convergence has been detected. • If -1, maximum number of iterations has been reached and even the residual norm estimates have not converged. • If -2, maximum number of iterations has been reached despite the residual norm estimates have converged (but the true residuals for eigenpairs have not). • If -3, the iterations stagnated and even the residual norm estimates have not converged. • If -4, the iterations stagnated while the eigenvalues have converged (but the true residuals for eigenpairs do not).
pm(11) to *pm*(129)	-	Reserved for future use.

Vector Mathematical Functions

Intel® oneAPI Math Kernel Library (oneMKL) Vector Mathematics functions (VM) compute a mathematical function of each of the vector elements. VM includes a set of highly optimized functions (arithmetic, power, trigonometric, exponential, hyperbolic, special, and rounding) that operate on vectors of real and complex numbers.

Application programs that improve performance with VM include nonlinear programming software, computation of integrals, financial calculations, computer graphics, and many others.

VM functions fall into the following groups according to the operations they perform:

- VM Mathematical Functions compute values of mathematical functions, such as sine, cosine, exponential, or logarithm, on vectors stored contiguously in memory.
- VM Pack/Unpack Functions convert to and from vectors with positive increment indexing, vector indexing, and mask indexing (see Appendix "Vector Arguments in VM" for details on vector indexing methods).
- VM Service Functions set/get the accuracy modes and the error codes, and free memory.

The VM mathematical functions take an input vector as an argument, compute values of the respective function element-wise, and return the results in an output vector. All the VM mathematical functions can perform in-place operations, where the input and output arrays are at the same memory locations. For VM mathematical functions with positive increment indexing, in-place operations are supported only when the input and output increments have the same value.

The Intel® oneAPI Math Kernel Library (oneMKL) interfaces are given in `mkl_vml.f90`; the `mkl_vml.fi` include file available in the previous versions of Intel® oneAPI Math Kernel Library (oneMKL) is retained for backward compatibility

Examples that demonstrate how to use the VM functions are located in:

`${MKL}/examples/vmlf/source`

See VM performance and accuracy data in the online VM Performance and Accuracy Data document available at https://www.intel.com/content/www/us/en/developer/tools/oneapi/onemkl-documentation.html.

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

VM Data Types, Accuracy Modes, and Performance Tips

VM includes mathematical and pack/unpack vector functions for single and double precision vector arguments of real and compex types. Intel® oneAPI Math Kernel Library (oneMKL) provides Fortran and C interfaces for all VM functions, including the associated service functions. The Function Naming Conventions topic shows how to call these functions.

Performance depends on a number of factors, including vectorization and threading overhead. The recommended usage is as follows:

- Use VM for vector lengths larger than 40 elements.
- Use the Intel® Compiler for vector lengths less than 40 elements.

All VM vector functions support the following accuracy modes:

- High Accuracy (HA), the default mode
- Low Accuracy (LA), which improves performance by reducing accuracy of the two least significant bits
- Enhanced Performance (EP), which provides better performance at the cost of significantly reduced accuracy. Approximately half of the bits in the mantissa are correct.

Note that using the EP mode does not guarantee accurate processing of corner cases and special values. Although the default accuracy is HA, LA is sufficient in most cases. For applications that require less accuracy (for example, media applications, some Monte Carlo simulations, etc.), the EP mode may be sufficient.

VM handles special values in accordance with the C99 standard [C99].

Intel® oneAPI Math Kernel Library (oneMKL) offers both functions and environment variables to switch between modes for VM. See the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for details about the environment variables. Use the `vmlsetmode(`*`mode`*`)` function (see Table "Values of the *mode* Parameter") to switch between the HA, LA, and EP modes. The `vmlgetmode()` function returns the current mode.

Function Naming Conventions

VM Naming Conventions

The VM function names are lowercase.

The VM mathematical and pack/unpack function names have the following structure:

`v[m]<?><name><mod>`

where

- *v* is a prefix indicating vector operations.
- `[m]` is an optional prefix for mathematical functions that indicates additional argument to specify a VM mode for a given function call (see `vmlsetmode` for possible values and their description).
- `<?>` is a precision prefix that indicates one of the following data types:

s	`REAL (KIND=4).`
d	`REAL (KIND=8).`
c	`COMPLEX (KIND=4).`
z	`COMPLEX (KIND=8).`

- `<name>` indicates the function short name. See examples in Table "VM Mathematical Functions".
- *<mod>* field is present only in the pack/unpack functions and indicates the indexing method used:

i	indexing with a positive increment
v	indexing with an index vector
m	indexing with a mask vector.

The VM service function names have the following structure:

vml`<name>`

where

`<name>` indicates the function short name. See examples in Table "VM Service Functions".

To call VM functions from an application program, use conventional function calls. For example, call the vector single precision real exponential function as

`call vsexp ( n, a, y )`

`call vmsexp ( n, a, y, mode )` with a specified mode

VM Function Interfaces

VM interfaces include the function names and argument lists. The following sections describe the interfaces for the VM functions. Note that some of the functions have multiple input and output arguments

Some VM functions may also take scalar arguments as input. See the function description for the naming conventions of such arguments.

VM Mathematical Function Interfaces

```
call v<?><name>( n, a, [scalar input arguments,]y )
call v<?><name>i( n, a, inca, [scalar input arguments,]y, incy )
call v<?><name>( n, a, b, [scalar input arguments,]y )
callv<?><name>i( n, a, inca, b, incb, [scalar input arguments,]y, incy )
call v<?><name>( n, a, y, z )
callv<?><name>i( n, a, inca, y, incy, z, incz )
call vm<?><name>( n, a, [scalar input arguments,]y, mode )
call vm<?><name>i( n, a, inca, [scalar input arguments,]y, incy, mode )
call vm<?><name>( n, a, b, [scalar input arguments,]y, mode )
callvm<?><name>i( n, a, inca, b, incb, [scalar input arguments,]y, incy, mode )
call vm<?><name>( n, a, y, z, mode )
callvm<?><name>i( n, a, inca, y, incy, z, incz, mode )
```

VM Mathematical Functions

VM Pack Function Interfaces

```
callv<?>packi( n, a, inca, y )
call v<?>packv( n, a, ia, y )
call v<?>packm( n, a, ma, y )
```

VM Unpack Function Interfaces

```
call v<?>unpacki( n, a, y, incy )
call v<?>unpackv( n, a, y, iy )
call v<?>unpackm( n, a, y, my )
```

VM Service Function Interfaces

```
oldmode = vmlsetmode( mode )
mode = vmlgetmode( )
olderr = vmlseterrstatus ( err )
err = vmlgeterrstatus( )
olderr = vmlclearerrstatus( )
oldcallback = vmlseterrorcallback( callback )
callback = vmlgeterrorcallback( )
oldcallback = vmlclearerrorcallback( )
```

Note that *oldmode*, *olderr*, and *oldcallback* refer to settings prior to the call.

VM Input Parameters

n	number of elements to be calculated
a	first input vector
b	second input vector
inca	vector increment for the input vector *a*
incb	vector increment for the input vector *b*
ia	index vector for the input vector *a*
ma	mask vector for the input vector *a*

incy	vector increment for the output vector *y*
incz	vector increment for the output vector *z*
iy	index vector for the output vector *y*
my	mask vector for the output vector *y*
err	error code
mode	VM mode
callback	address of the callback function

VM Output Parameters

y	first output vector
z	second output vector
err	error code
mode	VM mode
olderr	former error code
oldmode	former VM mode
callback	address of the callback function
oldcallback	address of the former callback function

See the data types of the parameters used in each function in the respective function description section. All Intel® oneAPI Math Kernel Library (oneMKL) VM mathematical functions can perform in-place operations. For VM mathematical functions with positive increment indexing, (for example, v?PowI), in-place operations are supported only when the input and output increments have the same value.

Vector Indexing Methods

Classic VM mathematical functions work with unit stride. Strided VM mathematical functions (names with "I" suffix) work with arbitrary integer increments. Increments may be positive, negative or equal to zero. For example:

```
VSEXPI (n, a, inca, r, incr)
```

is equivalent to:

```
for (i=0; i<n; i++)
{
    r[i * incr] = exp (a[i * inca]);
}
```

```
do i=1, n
    r((i-1)*incr+1) = EXP (a((i-1)*inca+1))
end do
```

where

i – current index,

inca – input index increment,

incr – output index increment.

n – the number of elements to be computed (important: *n* is not the maximum array size).

So, when calling `VSEXPI(n, a, inca, r, incr)` be sure that the input vector *a* is allocated at least for `1 + (n-1)*inca` elements and the result vector *r* has a space for `1 + (n-1)*incr` elements.

> **NOTE** The order of computations is not guaranteed and no array bounds-checking is performed; therefore, the results for overlapped and in-place arrays are not generally deterministic for increments other than 1.

For output index increment, equal to 0, the result is not deterministic and generally nonsensical.

Use negative increments to step from base pointers in reverse order.

For example:

```
VSEXPI (n, a, -2, r, -3)
```

is equivalent to:

```
do i=1, n
    r((i-1)*(-3)+1)  = EXP (a((i-1)*(-2)+1));
end do
```

> **NOTE** Pass pointers to the desired ending array element in memory as an argument for negative strides.

For example:

```
VSEXPI (n, a, 2, r(1000:), -3)
```

Use a zero increment for one fixed argument rather than an array.

For example:

```
VSMULI (n, a, 1, b, 0, r, 1)
```

is equivalent to:

```
do i=1, n
    r(i) = a(i) * b(1)
end do
```

VM Pack/Unpack functions use the following indexing methods to do this task:

- positive increment
- index vector
- mask vector

The indexing method used in a particular function is indicated by the indexing modifier (see the description of the *<mod>* field in Function Naming Conventions). For more information on the indexing methods, see Vector Arguments in VM.

VM Pack/Unpack Functions

VM Error Diagnostics

The VM mathematical functions incorporate the error handling mechanism, which is controlled by the following service functions:

`vmlgeterrstatus`, `vmlseterrstatus`, `vmlclearerrstatus`	These functions operate with a global variable called VM Error Status. The VM Error Status flags an error, a warning, or a successful execution of a VM function.

vmlgeterrcallback, vmlseterrcallback, vmlclearerrcallback	These functions enable you to customize the error handling. For example, you can identify a particular argument in a vector where an error occurred or that caused a warning.
vmlsetmode, vmlgetmode	These functions get and set a VM mode. If you set a new VM mode using the vmlsetmode function, you can store the previous VM mode returned by the routine and restore it at any point of your application.

If both an error and a warning situation occur during the function call, the VM Error Status variable keeps only the value of the error code. See Table "Values of the VM Error Status" for possible values. If a VM function does not encounter errors or warnings, it sets the VM Error Status to VML_STATUS_OK.

If you use incorrect input arguments to a VM function (VML_STATUS_BADSIZE and VML_STATUS_BADMEM), the function calls xerbla to report errors. See Table "Values of the VM Error Status" for details.

You can use the vmlsetmode and vmlgetmode functions to modify error handling behavior. Depending on the VM mode, the error handling behavior includes the following operations:

- setting the VM Error Status to a value corresponding to the observed error or warning
- writing error text information to the *stderr* stream
- raising the appropriate exception on an error, if necessary
- calling the additional error handler callback function that is set by vmlseterrorcallback.

See Also

vmlgeterrstatus Gets the VM Error Status.

vmlseterrstatus Sets the new VM Error Status according to *err* and stores the previous VM Error Status to *olderr*Sets the global VM Status according to new values and returns the previous VM Status.

vmlclearerrstatus Sets the VM Error Status to VML_STATUS_OK and stores the previous VM Error Status to *olderr*.

vmlseterrorcallback Sets the additional error handler callback function and gets the old callback function.

vmlgeterrorcallback Gets the additional error handler callback function.

vmlclearerrorcallback Deletes the additional error handler callback function and retrieves the former callback function.

vmlgetmode Gets the VM mode.

vmlsetmode Sets a new mode for VM functions according to the *mode* parameter and stores the previous VM mode to *oldmode*.

VM Mathematical Functions

This section describes VM functions that compute values of mathematical functions on real and complex vector arguments.

Each function is introduced by its short name, a brief description of its purpose, and the calling sequence for each type of data, as well as a description of the input/output arguments.

The input range of parameters is equal to the mathematical range of the input data type, unless the function description specifies input threshold values, which mark off the precision overflow, as follows:

- *FLT_MAX* denotes the maximum number representable in single precision real data type
- *DBL_MAX* denotes the maximum number representable in double precision real data type

Table "VM Mathematical Functions" lists available mathematical functions and associated data types.

VM Mathematical Functions

Function	Data Types	Description
Arithmetic Functions		

Function	Data Types	Description
v?add	*s*, *d*, *c*, *z*	Adds vector elements
v?sub	*s*, *d*, *c*, *z*	Subtracts vector elements
v?sqr	*s*, *d*	Squares vector elements
v?mul	*s*, *d*, *c*, *z*	Multiplies vector elements
v?mulbyconj	*c*, *z*	Multiplies elements of one vector by conjugated elements of the second vector
v?conj	*c*, *z*	Conjugates vector elements
v?abs	*s*, *d*, *c*, *z*	Computes the absolute value of vector elements
v?arg	*c*, *z*	Computes the argument of vector elements
v?linearfrac	*s*, *d*	Performs linear fraction transformation of vectors
v?fmod	*s*, *d*	Performs element by element computation of the modulus function of vector *a* with respect to vector *b*
v?remainder	*s*, *d*	Performs element by element computation of the remainder function on the elements of vector *a* and the corresponding elements of vector *b*
Power and Root Functions		
v?inv	*s*, *d*	Inverts vector elements
v?div	*s*, *d*, *c*, *z*	Divides elements of one vector by elements of the second vector
v?sqrt	*s*, *d*, *c*, *z*	Computes the square root of vector elements
v?invsqrt	*s*, *d*	Computes the inverse square root of vector elements
v?cbrt	*s*, *d*	Computes the cube root of vector elements
v?invcbrt	*s*, *d*	Computes the inverse cube root of vector elements
v?pow2o3	*s*, *d*	Computes the cube root of the square of each vector element
v?pow3o2	*s*, *d*	Computes the square root of the cube of each vector element
v?pow	*s*, *d*, *c*, *z*	Raises each vector element to the specified power
v?powx	*s*, *d*, *c*, *z*	Raises each vector element to the constant power
v?powr	*s*, *d*	Computes *a* to the power *b* for elements of two vectors, where the elements of vector argument *a* are all non-negative
v?hypot	*s*, *d*	Computes the square root of sum of squares
Exponential and Logarithmic Functions		
v?exp	*s*, *d*, *c*, *z*	Computes the base *e* exponential of vector elements
v?exp2	*s*, *d*	Computes the base 2 exponential of vector elements
v?exp10	*s*, *d*	Computes the base 10 exponential of vector elements
v?expm1	*s*, *d*	Computes the base *e* exponential of vector elements decreased by 1
v?ln	*s*, *d*, *c*, *z*	Computes the natural logarithm of vector elements
v?log2	*s*, *d*	Computes the base 2 logarithm of vector elements
v?log10	*s*, *d*, *c*, *z*	Computes the base 10 logarithm of vector elements
v?log1p	*s*, *d*	Computes the natural logarithm of vector elements that are increased by 1
v?logb	*s*, *d*	Computes the exponents of the elements of input vector *a*
Trigonometric Functions		
v?cos	*s*, *d*, *c*, *z*	Computes the cosine of vector elements
v?sin	*s*, *d*, *c*, *z*	Computes the sine of vector elements
v?sincos	*s*, *d*	Computes the sine and cosine of vector elements
v?cis	*c*, *z*	Computes the complex exponent of vector elements (cosine and sine combined to complex value)
v?tan	*s*, *d*, *c*, *z*	Computes the tangent of vector elements
v?acos	*s*, *d*, *c*, *z*	Computes the inverse cosine of vector elements
v?asin	*s*, *d*, *c*, *z*	Computes the inverse sine of vector elements
v?atan	*s*, *d*, *c*, *z*	Computes the inverse tangent of vector elements
v?atan2	*s*, *d*	Computes the four-quadrant inverse tangent of ratios of the elements of two vectors

Function	Data Types	Description
v?cospi	*s*, *d*	Computes the cosine of vector elements multiplied by *π*
v?sinpi	*s*, *d*	Computes the sine of vector elements multiplied by *π*
v?tanpi	*s*, *d*	Computes the tangent of vector elements multiplied by *π*
v?acospi	*s*, *d*	Computes the inverse cosine of vector elements divided by *π*
v?asinpi	*s*, *d*	Computes the inverse sine of vector elements divided by *π*
v?atanpi	*s*, *d*	Computes the inverse tangent of vector elements divided by *π*
v?atan2pi	*s*, *d*	Computes the four-quadrant inverse tangent of the ratios of the corresponding elementss of two vectors divided by *π*
v?cosd	*s*, *d*	Computes the cosine of vector elements multiplied by *π*/180
v?sind	*s*, *d*	Computes the sine of vector elements multiplied by *π*/180
v?tand	*s*, *d*	Computes the tangent of vector elements multiplied by *π*/180
Hyperbolic Functions		
v?cosh	*s*, *d*, *c*, *z*	Computes the hyperbolic cosine of vector elements
v?sinh	*s*, *d*, *c*, *z*	Computes the hyperbolic sine of vector elements
v?tanh	*s*, *d*, *c*, *z*	Computes the hyperbolic tangent of vector elements
v?acosh	*s*, *d*, *c*, *z*	Computes the inverse hyperbolic cosine of vector elements
v?asinh	*s*, *d*, *c*, *z*	Computes the inverse hyperbolic sine of vector elements
v?atanh	*s*, *d*, *c*, *z*	Computes the inverse hyperbolic tangent of vector elements.
Special Functions		
v?erf	*s*, *d*	Computes the error function value of vector elements
v?erfc	*s*, *d*	Computes the complementary error function value of vector elements
v?cdfnorm	*s*, *d*	Computes the cumulative normal distribution function value of vector elements
v?erfinv	*s*, *d*	Computes the inverse error function value of vector elements
v?erfcinv	*s*, *d*	Computes the inverse complementary error function value of vector elements
v?cdfnorminv	*s*, *d*	Computes the inverse cumulative normal distribution function value of vector elements
v?lgamma	*s*, *d*	Computes the natural logarithm for the absolute value of the gamma function of vector elements
v?tgamma	*s*, *d*	Computes the gamma function of vector elements
v?expint1	*s*, *d*	Computes the exponential integral of vector elements
Rounding Functions		
v?floor	*s*, *d*	Rounds towards minus infinity
v?ceil	*s*, *d*	Rounds towards plus infinity
v?trunc	*s*, *d*	Rounds towards zero infinity
v?round	*s*, *d*	Rounds to nearest integer
v?nearbyint	*s*, *d*	Rounds according to current mode
v?rint	*s*, *d*	Rounds according to current mode and raising inexact result exception
v?modf	*s*, *d*	Computes the integer and fractional parts
v?frac	*s*, *d*	Computes the fractional part
Miscellaneous Functions		
v?copysign	*s*, *d*	Returns vector of elements of one argument with signs changed to match other argument elements
v?nextafter	*s*, *d*	Returns vector of elements containing the next representable floating-point values following the values from the elements of one vector in the direction of the corresponding elements of another vector
v?fdim	*s*, *d*	Returns vector containing the differences of the corresponding elements of the vector arguments if the first is larger and +0 otherwise
v?fmax	*s*, *d*	Returns the larger of each pair of elements of the two vector arguments

Function	Data Types	Description
v?fmin	*s*, *d*	Returns the smaller of each pair of elements of the two vector arguments
v?maxmag	*s*, *d*	Returns the element with the larger magnitude between each pair of elements of the two vector arguments
v?minmag	*s*, *d*	Returns the element with the smaller magnitude between each pair of elements of the two vector arguments

Special Value Notations

This topic defines notations of special values for complex functions. The definitions are provided in text, tables, or formulas.

- `z`, `z1`, `z2`, etc. denote complex numbers.
- `i`, $i^2=-1$ is the imaginary unit.
- `x`, `X`, `x1`, `x2`, etc. denote real imaginary parts.
- `y`, `Y`, `y1`, `y2`, etc. denote imaginary parts.
- `X` and `Y` represent any finite positive IEEE-754 floating point values, if not stated otherwise.
- Quiet `NaN` and signaling `NaN` are denoted with `QNAN` and `SNAN`, respectively.
- The IEEE-754 positive infinities or floating-point numbers are denoted with a `+` sign before `X`, `Y`, etc.
- The IEEE-754 negative infinities or floating-point numbers are denoted with a – sign before `X`, `Y`, etc.

`CONJ(z)` and `CIS(z)` are defined as follows:

`CONJ(x+i·y)=x–i·y`

`CIS(y)=cos(y)+i·sin(y).`

The special value tables show the result of the function for the `z` argument at the intersection of the `RE(z)` column and the `i*IM(z)` row. If the function raises an exception on the argument `z`, the lower part of this cell shows the raised exception and the VM Error Status. An empty cell indicates that this argument is normal and the result is defined mathematically.

Arithmetic Functions

Arithmetic functions perform the basic mathematical operations like addition, subtraction, multiplication or computation of the absolute value of the vector elements.

v?Add

Performs element by element addition of vector a and vector b.

Syntax

```
call vsadd( n, a, b, y )
call vsaddi(n, a, inca, b, incb, y, incy)
call vmsadd( n, a, b, y, mode )
call vmsaddi(n, a, inca, b, incb, y, incy, mode)
call vdadd( n, a, b, y )
call vdaddi(n, a, inca, b, incb, y, incy)
call vmdadd( n, a, b, y, mode )
call vmdaddi(n, a, inca, b, incb, y, incy, mode)
call vcadd( n, a, b, y )
call vcaddi(n, a, inca, b, incb, y, incy)
```

```
call vmcadd( n, a, b, y, mode )
call vmcaddi(n, a, inca, b, incb, y, incy, mode)
call vzadd( n, a, b, y )
call vzaddi(n, a, inca, b, incb, y, incy)
call vmzadd( n, a, b, y, mode )
call vmzaddi(n, a, inca, b, incb, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a, *b*	DOUBLE PRECISION for vdadd, vmdadd COMPLEX for vcadd, vmcadd DOUBLE COMPLEX for vzadd, vmzadd REAL, INTENT(IN) for vsAdd, vmsAdd DOUBLE PRECISION, INTENT(IN) for vdadd, vmdadd COMPLEX, INTENT(IN) for vcadd, vmcadd DOUBLE COMPLEX, INTENT(IN) for vzadd, vmzadd	Arrays that specify the input vectors *a* and *b*.
inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdadd, vmdadd COMPLEX, for vcadd, vmcadd DOUBLE COMPLEX for vzadd, vmzadd REAL, INTENT(OUT) for vsAdd, vmsAdd	Array that specifies the output vector *y*.

Name	Type	Description
	DOUBLE PRECISION, INTENT(OUT) for vdadd, vmdadd	
	COMPLEX, INTENT(OUT) for vcadd, vmcadd	
	DOUBLE COMPLEX, INTENT(OUT) for vzadd, vmzadd	

Description

The v?Add function performs element by element addition of vector *a* and vector *b*.

Special values for Real Function v?Add

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
+0	-0	+0	
-0	+0	+0	
-0	-0	-0	
+∞	+∞	+∞	
+∞	-∞	QNAN	INVALID
-∞	+∞	QNAN	INVALID
-∞	-∞	-∞	
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	non-SNAN	QNAN	
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

```
Add(x1+i*y1,x2+i*y2) = (x1+x2) + i*(y1+y2)
```

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when all RE(x), RE(y), IM(x), IM(y) arguments are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VM Error Status to VML_STATUS_OVERFLOW (overriding any possible VML_STATUS_ACCURACYWARNING status).

v?Sub

Performs element by element subtraction of vector b from vector a.

Syntax

```
call vssub( n, a, b, y )
call vssubi(n, a, inca, b, incb, y, incy)
call vmssub( n, a, b, y, mode )
call vmssubi(n, a, inca, b, incb, y, incy, mode)
call vdsub( n, a, b, y )
call vdsubi(n, a, inca, b, incb, y, incy)
call vmdsub( n, a, b, y, mode )
```

```
call vmdsubi(n, a, inca, b, incb, y, incy, mode)
call vcsub( n, a, b, y )
call vcsubi(n, a, inca, b, incb, y, incy)
call vmcsub( n, a, b, y, mode )
call vmcsubi(n, a, inca, b, incb, y, incy, mode)
call vzsub( n, a, b, y )
call vzsubi(n, a, inca, b, incb, y, incy)
call vmzsub( n, a, b, y, mode )
call vmzsubi(n, a, inca, b, incb, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a, *b*	DOUBLE PRECISION for vdsub, vmdsub COMPLEX for vcsub, vmcsub DOUBLE COMPLEX for vzsub, vmzsub REAL, INTENT(IN) for vssub, vmssub DOUBLE PRECISION, INTENT(IN) for vdsub, vmdsub COMPLEX, INTENT(IN) for vcsub, vmcsub DOUBLE COMPLEX, INTENT(IN) for vzsub, vmzsub	Arrays that specify the input vectors *a* and *b*.
inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vssub, vmssub DOUBLE PRECISION for vdsub, vmdsub	Array that specifies the output vector *y*.

Name	Type	Description
	COMPLEX for vcsub, vmcsub	
	DOUBLE COMPLEX for vzsub, vmzsub	
	REALINTENT(OUT) for vssub, vmssub	
	DOUBLE PRECISION, INTENT(OUT) for vdsub, vmdsub	
	COMPLEX, INTENT(OUT) for vcsub, vmcsub	
	DOUBLE COMPLEX, INTENT(OUT) for vzsub, vmzsub	

Description

The v?Sub function performs element by element subtraction of vector *b* from vector *a*.

Special values for Real Function v?Sub(x)

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
+0	-0	+0	
-0	+0	-0	
-0	-0	+0	
+∞	+∞	QNAN	INVALID
+∞	-∞	+∞	
-∞	+∞	-∞	
-∞	-∞	QNAN	INVALID
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	non-SNAN	QNAN	
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

Sub(x1+i*y1,x2+i*y2) = (x1-x2) + i*(y1-y2).

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when all RE(x), RE(y), IM(x), IM(y) arguments are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VM Error Status to VML_STATUS_OVERFLOW (overriding any possible VML_STATUS_ACCURACYWARNING status).

v?Sqr

Performs element by element squaring of the vector.

Syntax

```
call vssqr( n, a, y )
call vssqri(n, a, inca, y, incy)
call vmssqr( n, a, y, mode )
call vmssqri(n, a, inca, y, incy, mode)
```

```
call vdsqr( n, a, y )
call vdsqri(n, a, inca, y, incy)
call vmdsqr( n, a, y, mode )
call vmdsqri(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdsqr, vmdsqr REAL, INTENT(IN) for vssqr, vmssqr DOUBLE PRECISION, INTENT(IN) for vdsqr, vmdsqr	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdsqr, vmdsqr REAL, INTENT(OUT) for vssqr, vmssqr DOUBLE PRECISION, INTENT(OUT) for vdsqr, vmdsqr	Array that specifies the output vector *y*.

Description

The v?Sqr function performs element by element squaring of the vector.

Special Values for Real Function v?Sqr(x)

Argument	Result	Exception
+0	+0	
-0	+0	
+∞	+∞	
-∞	+∞	
QNAN	QNAN	
SNAN	QNAN	INVALID

v?Mul

Performs element by element multiplication of vector a and vector b.

Syntax

```
call vsmul( n, a, b, y )
call vsmuli(n, a, inca, b, incb, y, incy)
call vmsmul( n, a, b, y, mode )
call vmsmuli(n, a, inca, b, incb, y, incy, mode)
call vdmul( n, a, b, y )
call vdmuli(n, a, inca, b, incb, y, incy)
call vmdmul( n, a, b, y, mode )
call vmdmuli(n, a, inca, b, incb, y, incy, mode)
call vcmul( n, a, b, y )
call vcmuli(n, a, inca, b, incb, y, incy)
call vmcmul( n, a, b, y, mode )
call vmcmuli(n, a, inca, b, incb, y, incy, mode)
call vzmul( n, a, b, y )
call vzmuli(n, a, inca, b, incb, y, incy)
call vmzmul( n, a, b, y, mode )
call vmzmuli(n, a, inca, b, incb, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a, *b*	DOUBLE PRECISION for vdmul, vmdmul COMPLEX for vcmul, vmcmul DOUBLE COMPLEX for vzmul, vmzmul REAL, INTENT(IN) for vsmul, vmsmul DOUBLE PRECISION, INTENT(IN) for vdmul, vmdmul COMPLEX, INTENT(IN) for vcmul, vmcmul DOUBLE COMPLEX, INTENT(IN) for vzmul, vmzmul	Arrays that specify the input vectors *a* and *b*.

Name	Type	Description
inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdmul, vmdmul COMPLEX, for vcmul, vmcmul DOUBLE COMPLEX for vzmul, vmzmul REAL, INTENT(OUT) for vsmul, vmsmul DOUBLE PRECISION, INTENT(OUT) for vdmul, vmdmul COMPLEX, INTENT(OUT) for vcmul, vmcmul DOUBLE COMPLEX, INTENT(OUT) for vzmul, vmzmul	Array that specifies the output vector *y*.

Description

The v?Mul function performs element by element multiplication of vector *a* and vector *b*.

Special values for Real Function v?Mul(x)

SNAN	any value	QNAN	INVALID

Argument 1	Argument 2	Result	Exception
any value	SNAN	QNAN	INVALID
QNAN	non-SNAN	QNAN	
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

`Mul(x1+i*y1,x2+i*y2) = (x1*x2-y1*y2) + i*(x1*y2+y1*x2).`

Overflow in a complex function occurs (supported in the `HA`/`LA` accuracy modes only) when all `RE(x)`, `RE(y)`, `IM(x)`, `IM(y)` arguments are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

v?MulByConj

Performs element by element multiplication of vector a element and conjugated vector b element.

Syntax

```
call vcmulbyconj( n, a, b, y )
call vsmulbyconji(n, a, inca, b, incb, y, incy)
call vmcmulbyconj( n, a, b, y, mode )
call vmsmulbyconji(n, a, inca, b, incb, y, incy, mode)
call vzmulbyconj( n, a, b, y )
call vdmulbyconji(n, a, inca, b, incb, y, incy)
call vmzmulbyconj( n, a, b, y, mode )
call vmdmulbyconji(n, a, inca, b, incb, y, incy, mode)
```

Include Files

- `mkl_vml.f90`

Input Parameters

Name	Type	Description
n	`INTEGER, INTENT(IN)`	Specifies the number of elements to be calculated.

a, *b*	`DOUBLE COMPLEX` for `vzmulbyconj`, `vmzmulbyconj`
	`COMPLEX, INTENT(IN)` for `vcmulbyconj`, `vmcmulbyconj`
	`DOUBLE COMPLEX, INTENT(IN)` for `vzmulbyconj`, `vmzmulbyconj`
		Arrays that specify the input vectors *a* and *b*.

inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.

Name	Type	Description
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE COMPLEX for vzmulbyconj, vmzmulbyconj COMPLEX, INTENT(OUT) for vcmulbyconj, vmcmulbyconj DOUBLE COMPLEX, INTENT(OUT) for vzmulbyconj, vmzmulbyconj	Array that specifies the output vector *y*.

Description

The v?MulByConj function performs element by element multiplication of vector *a* element and conjugated vector *b* element.

Specifications for special values of the functions are found according to the formula

MulByConj(x1+i*y1,x2+i*y2) = Mul(x1+i*y1,x2-i*y2).

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when all RE(x), RE(y), IM(x), IM(y) arguments are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VM Error Status to VML_STATUS_OVERFLOW (overriding any possible VML_STATUS_ACCURACYWARNING status).

v?Conj

Performs element by element conjugation of the vector.

Syntax

```
call vcconj( n, a, y )
call vcconji(n, a, inca, y, incy)
call vmcconj( n, a, y, mode )
call vmcconji(n, a, inca, y, incy, mode)
call vzconj( n, a, y )
call vzconji(n, a, inca, y, incy)
call vmzconj( n, a, y, mode )
call vmzconji(n, a, inca, y, incy, mode)
```

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE COMPLEX, INTENT(IN) for vzconj, vmzconj COMPLEX, INTENT(IN) for vcconj, vmcconj DOUBLE COMPLEX, INTENT(IN) for vzconj, vmzconj	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE COMPLEX for vzconj, vmzconj COMPLEX, INTENT(OUT) for vcconj, vmcconj DOUBLE COMPLEX, INTENT(OUT) for vzconj, vmzconj	Array that specifies the output vector *y*.

Description

The v?Conj function performs element by element conjugation of the vector.

No special values are specified. The function does not raise floating-point exceptions.

v?Abs

Computes absolute value of vector elements.

Syntax

```
call vsabs( n, a, y )
call vsabsi(n, a, inca, y, incy)
call vmsabs( n, a, y, mode )
call vmsabsi(n, a, inca, y, incy, mode)
call vdabs( n, a, y )
call vdabsi(n, a, inca, y, incy)
call vmdabs( n, a, y, mode )
call vmdabsi(n, a, inca, y, incy, mode)
call vcabs( n, a, y )
```

```
call vcabsi(n, a, inca, y, incy)
call vmcabs( n, a, y, mode )
call vmcabsi(n, a, inca, y, incy, mode)
call vzabs( n, a, y )
call vzabsi(n, a, inca, y, incy)
call vmzabs( n, a, y, mode )
call vmzabsi(n, a, inca, y, incy, mode)
```

Include Files

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdabs, vmdabs COMPLEX for vcabs, vmcabs DOUBLE COMPLEX for vzabs, vmzabs REAL, INTENT(IN) for vsabs, vmsabs DOUBLE PRECISION, INTENT(IN) for vdabs, vmdabs COMPLEX, INTENT(IN) for vcabs, vmcabs DOUBLE COMPLEX, INTENT(IN) for vzabs, vmzabs	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT (IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdabs, vmdabs, vzabs, vmzabs REAL, INTENT(OUT) for vsabs, vmsabs, vcabs, vmcabs DOUBLE PRECISION, INTENT(OUT) for vdabs, vmdabs, vzabs, vmzabs	Array that specifies the output vector *y*.

Description

The v?Abs function computes an absolute value of vector elements.

Special Values for Real Function v?Abs(x)

Argument	Result	Exception
+0	+0	
-0	+0	
+∞	+∞	
-∞	+∞	
QNAN	QNAN	
SNAN	QNAN	INVALID

Specifications for special values of the complex functions are defined according to the following formula

Abs(z) = Hypot(RE(z),IM(z)).

v?Arg

Computes argument of vector elements.

Syntax

```
call vcarg( n, a, y )
call vcargi(n, a, inca, y, incy)
call vmcarg( n, a, y, mode )
call vmcargi(n, a, inca, y, incy, mode)
call vzarg( n, a, y )
call vzargi(n, a, inca, y, incy)
call vmzarg( n, a, y, mode )
call vmzargi(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	COMPLEX for vcarg, vmcarg DOUBLE COMPLEX for vzarg, vmzarg COMPLEX, INTENT(IN) for vcarg, vmcarg DOUBLE COMPLEX, INTENT(IN) for vzarg, vmzarg	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.

Name	Type	Description
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vzarg, vmzarg REAL, INTENT(OUT) for vcarg, vmcarg DOUBLE PRECISION, INTENT(OUT) for vzarg, vmzarg	Array that specifies the output vector *y*.

Description

The v?Arg function computes argument of vector elements.

See Special Value Notations for the conventions used in the table below.

Special Values for Complex Function v?Arg(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	+3·π/4	+π/2	+π/2	+π/2	+π/2	+π/4	NAN
+i·Y	+π		+π/2	+π/2		+0	NAN
+i·0	+π	+π	+π	+0	+0	+0	NAN
-i·0	-π	-π	-π	-0	-0	-0	NAN
-i·Y	-π		-π/2	-π/2		-0	NAN
-i·∞	-3·π/4	-π/2	-π/2	-π/2	-π/2	-π/4	NAN
+i·NAN	NAN	NAN	NAN	NAN	NAN	NAN	NAN

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN
- Arg(z)=Atan2(IM(z),RE(z)).

v?LinearFrac

Performs linear fraction transformation of vectors a and b with scalar parameters.

Syntax

```
call vslinearfrac( n, a, b, scalea, shifta, scaleb, shiftb, y )
call vslinearfraci(n, a, inca, b, incb, scalea, shifta, scaleb, shiftb, y, incy)
call vmslinearfrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode )
call vmslinearfraci(n, a, inca, b, incb, scalea, shifta, scaleb, shiftb, y, incy, mode)
call vdlinearfrac( n, a, b, scalea, shifta, scaleb, shiftb, y )
```

```
call vdlinearfraci(n, a, inca, b, incb, scalea, shifta, scaleb, shiftb, y, incy)
call vmdlinearfrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode )
call vmdlinearfraci(n, a, inca, b, incb, scalea, shifta, scaleb, shiftb, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a, *b*	DOUBLE PRECISION for vdlinearfrac, vmdlinearfrac REAL, INTENT(IN) for vslinearfrac, vmslinearfrac DOUBLE PRECISION, INTENT(IN) for vdlinearfrac, vmdlinearfrac	Arrays that specify the input vectors *a* and *b*.
inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
scalea, *scaleb*	DOUBLE PRECISION for vdlinearfrac, vmdlinearfrac REAL, INTENT(IN) for vslinearfrac, vmslinearfrac DOUBLE PRECISION, INTENT(IN) for vdlinearfrac, vmdlinearfrac	Constant values for scaling multipliers of vectors *a* and *b*.
shifta, *shiftb*	DOUBLE PRECISION for vdlinearfrac, vmdlinearfrac REAL, INTENT(IN) for vslinearfrac, vmslinearfrac DOUBLE PRECISION, INTENT(IN) for vdlinearfrac, vmdlinearfrac	Constant values for shifting addends of vectors *a* and *b*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdlinearfrac, vmdlinearfrac REAL, INTENT(OUT) for vslinearfrac, vmslinearfrac	Array that specifies the output vector *y*.

Name	Type	Description
	DOUBLE PRECISION, INTENT(OUT) for vdlinearfrac, vmdlinearfrac	

Description

The v?LinearFrac function performs a linear fraction transformation of vector *a* by vector *b* with scalar parameters: scaling multipliers *scalea*, *scaleb* and shifting addends *shifta*, *shiftb*:

$y[i]=(scalea \cdot a[i]+shifta)/(scaleb \cdot b[i]+shiftb)$, $i=1,2 \ldots n$

The v?LinearFrac function is implemented in the EP accuracy mode only, therefore no special values are defined for this function. If used in HA or LA mode, v?LinearFrac sets the VM Error Status to VML_STATUS_ACCURACYWARNING (see the Values of the VM Status table). Correctness is guaranteed within the threshold limitations defined for each input parameter (see the table below); otherwise, the behavior is unspecified.

Threshold Limitations on Input Parameters
$2^{E_{MIN}/2} \le \lvert scalea \rvert \le 2^{(E_{MAX}-2)/2}$
$2^{E_{MIN}/2} \le \lvert scaleb \rvert \le 2^{(E_{MAX}-2)/2}$
$\lvert shifta \rvert \le 2^{E_{MAX}-2}$
$\lvert shiftb \rvert \le 2^{E_{MAX}-2}$
$2^{E_{MIN}/2} \le a[i] \le 2^{(E_{MAX}-2)/2}$
$2^{E_{MIN}/2} \le b[i] \le 2^{(E_{MAX}-2)/2}$
$a[i] \neq -(shifta/scalea)*(1-\delta_1), \lvert\delta_1\rvert \le 2^{1-(p-1)/2}$
$b[i] \neq -(shiftb/scaleb)*(1-\delta_2), \lvert\delta_2\rvert \le 2^{1-(p-1)/2}$

E_{MIN} and E_{MAX} are the minimum and maximum exponents and *p* is the number of significant bits (precision) for the corresponding data type according to the ANSI/IEEE Standard 754-2008 ([IEEE754]):

- for single precision E_{MIN} = -126, E_{MAX} = 127, p = 24
- for double precision E_{MIN} = -1022, E_{MAX} = 1023, p = 53

The thresholds become less strict for common cases with *scalea*=0 and/or *scaleb*=0:

- if *scalea*=0, there are no limitations for the values of *a*[i] and *shifta*.
- if *scaleb*=0, there are no limitations for the values of *b*[i] and *shiftb*.

Example

To use the v?linearfrac to shift vector *a* by a scalar value, set *scaleb* to 0. Note that even if *scaleb* is 0, *b* must be declared.

To use the v?linearfrac to compute *shifta*/(*scaleb*·*b*[*i*]+*shiftb*), set *scalea* to 0. Note that even if *scalea* is 0, *a* must be declared.

v?Fmod

The v?Fmod *function performs element by element computation of the modulus function of vector a with respect to vector b.*

Syntax

```
call vsfmod (n, a, b, y )
call vsfmodi(n, a, inca, b, incb, y, incy)
call vmsfmod (n, a, b, y, mode )
call vmsfmodi(n, a, inca, b, incb, y, incy, mode)
call vdfmod (n, a, b, y )
call vdfmodi(n, a, inca, b, incb, y, incy)
call vmdfmod (n, a, b, y, mode )
call vmdfmodi(n, a, inca, b, incb, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER	Specifies the number of elements to be calculated.
a, b	REAL for vsFmod REAL for vmsFmod DOUBLE PRECISION for vdFmod DOUBLE PRECISION for vmdFmod	Pointers to arrays containing the input vectors *a* and *b*.
inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
mode	INTEGER (KIND=8)	Overrides the global VM *mode* setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	REAL for vsFmod REAL for vmsFmod DOUBLE PRECISION for vdFmod DOUBLE PRECISION for vmdFmod	Pointer to an array containing the output vector *y*.

Description

The v?Fmod function computes the modulus function of each element of vector *a*, with respect to the corresponding elements of vector *b*:

$a_i - b_i * \mathrm{trunc}(a_i/b_i)$

In general, the modulus function fmod (a_i, b_i) returns the value $a_i - n*b_i$ for some integer *n* such that if b_i is nonzero, the result has the same sign as a_i and a magnitude less than the magnitude of b_i.

Special values for Real Function v?Fmod(x, y)

Argument 1	Argument 2	Result	VM Error Status	Exception
x not NAN	±0	NAN	VML_STATUS_SING	INVALID
±∞	*y* not NAN	NAN	VML_STATUS_SING	INVALID
±0	*y*≠ 0, not NAN	±0		
x finite	±∞	*x*		UNDERFLOW if *x* is subnormal
NAN	*y*	NAN		
x	NAN	NAN		

NOTE
If element *i* in the result of `v?Fmod` is 0, its sign is that of a_i.

See Also

Div Performs element by element division of vector *a* by vector *b*

Remainder Performs element by element computation of the remainder function on the elements of vector *a* and the corresponding elements of vector *b*.

v?Remainder

Performs element by element computation of the remainder function on the elements of vector a and the corresponding elements of vector b.

Syntax

```
call vsremainder (n, a, b, y )
call vsremainderi(n, a, inca, b, incb, y, incy)
call vmsremainder (n, a, b, y, mode )
call vmsremainderi(n, a, inca, b, incb, y, incy, mode)
call vdremainder (n, a, b, y )
call vdremainderi(n, a, inca, b, incb, y, incy)
call vmdremainder (n, a, b, y, mode )
call vmdremainderi(n, a, inca, b, incb, y, incy, mode)
```

Include Files

- `mkl_vml.f90`

Input Parameters

Name	Type	Description
n	`INTEGER`	Specifies the number of elements to be calculated.

a, b	`REAL` for `vsRemainder`
	`REAL` for `vmsRemainder`
	`DOUBLE PRECISION` for `vdRemainder`
		Pointers to arrays containing the input vectors *a* and *b*.

Name	Type	Description
	DOUBLE PRECISION for vmdRemainder	
inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
mode	INTEGER (KIND=8)	Overrides the global VM *mode* setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	REAL for vsRemainder REAL for vmsRemainder DOUBLE PRECISION for vdRemainder DOUBLE PRECISION for vmdRemainder	Pointer to an array containing the output vector *y*.

Description

Computes the remainder of each element of vector *a*, with respect to the corresponding elements of vector *b*: compute the values of *n* such that

$n = a_i - n*b_i$

where *n* is the integer nearest to the exact value of a_i/b_i. If two integers are equally close to a_i/b_i, *n* is the even one. If *n* is zero, it has the same sign as a_i.

Special values for Real Function v?Remainder(x, y)

Argument 1	Argument 2	Result	VM Error Status	Exception
x not NAN	±0	NAN	VML_STATUS_DOM	INVALID
±∞	*y* not NAN	NAN		INVALID
±0	$y \neq 0$, not NAN	±0		
x finite	±∞	*x*		UNDERFLOW if *x* is subnormal
NAN	*y*	NAN		
x	NAN	NAN		

NOTE
If element *i* in the result of v?Remainder is 0, its sign is that of a_i.

See Also

Div Performs element by element division of vector *a* by vector *b*

Fmod The v?Fmod function performs element by element computation of the modulus function of vector *a* with respect to vector *b*.

Power and Root Functions

v?Inv

Performs element by element inversion of the vector.

Syntax

```
call vsinv( n, a, y )
call vsinvi(n, a, inca, y, incy)
call vmsinv( n, a, y, mode )
call vmsinvi(n, a, inca, y, incy, mode)
call vdinv( n, a, y )
call vdinvi(n, a, inca, y, incy)

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdinv, vmdinv REAL, INTENT(IN) for vsinv, vmsinv DOUBLE PRECISION, INTENT(IN) for vdinv, vmdinv	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdinv, vmdinv REAL, INTENT(OUT) for vsinv, vmsinv DOUBLE PRECISION, INTENT(OUT) for vdinv, vmdinv	Array that specifies the output vector *y*.

Description

The v?Inv function performs element by element inversion of the vector.

Special Values for Real Function v?Inv(x)

Argument	Result	VM Error Status	Exception
+0	+∞	VML_STATUS_SING	ZERODIVIDE
-0	-∞	VML_STATUS_SING	ZERODIVIDE
+∞	+0		
-∞	-0		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Div

Performs element by element division of vector a by vector b

Syntax

```
call vsdiv( n, a, b, y )
call vsdivi(n, a, inca, b, incb, y, incy)
call vmsdiv( n, a, b, y, mode )
call vmsdivi(n, a, inca, b, incb, y, incy, mode)
call vddiv( n, a, b, y )
call vddivi(n, a, inca, b, incb, y, incy)
call vmddiv( n, a, b, y, mode )
call vmddivi(n, a, inca, b, incb, y, incy, mode)
call vcdiv( n, a, b, y )
call vcdivi(n, a, inca, b, incb, y, incy)
call vmcdiv( n, a, b, y, mode )
call vmcdivi(n, a, inca, b, incb, y, incy, mode)
call vzdiv( n, a, b, y )
call vzdivi(n, a, inca, b, incb, y, incy)
call vmzdiv( n, a, b, y, mode )
call vmzdivi(n, a, inca, b, incb, y, incy, mode)
```

Include Files

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a, *b*	DOUBLE PRECISION for vddiv, vmddiv COMPLEX for vcdiv, vmcdiv	Arrays that specify the input vectors *a* and *b*.

Name	Type	Description
	DOUBLE COMPLEX for vzdiv, vmzdiv REAL, INTENT(IN) for vsdiv, vmsdiv DOUBLE PRECISION, INTENT(IN) for vddiv, vmddiv COMPLEX, INTENT(IN) for vcdiv, vmcdiv DOUBLE COMPLEX, INTENT(IN) for vzdiv, vmzdiv	
inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Div Function

Data Type	Threshold Limitations on Input Parameters
single precision	abs(*a*[i]) < abs(*b*[i]) * FLT_MAX
double precision	abs(*a*[i]) < abs(*b*[i]) * DBL_MAX

Precision overflow thresholds for the complex v?Div function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vddiv, vmddiv COMPLEX for vcdiv, vmcdiv DOUBLE COMPLEX for vzdiv, vmzdiv REAL, INTENT(OUT) for vsdiv, vmsdiv DOUBLE PRECISION, INTENT(OUT) for vddiv, vmddiv COMPLEX, INTENT(OUT) for vcdiv, vmcdiv DOUBLE COMPLEX, INTENT(OUT) for vzdiv, vmzdiv	Array that specifies the output vector *y*.

Description

The v?Div function performs element by element division of vector *a* by vector *b*.

Special values for Real Function v?Div(x)

Argument 1	Argument 2	Result	VM Error Status	Exception
X > +0	+0	+∞	VML_STATUS_SING	ZERODIVIDE

Argument 1	Argument 2	Result	VM Error Status	Exception
X > +0	-0	-∞	VML_STATUS_SING	ZERODIVIDE
X < +0	+0	-∞	VML_STATUS_SING	ZERODIVIDE
X < +0	-0	+∞	VML_STATUS_SING	ZERODIVIDE
+0	+0	QNAN	VML_STATUS_SING	
-0	-0	QNAN	VML_STATUS_SING	
X > +0	+∞	+0		
X > +0	-∞	-0		
+∞	+∞	QNAN		
-∞	-∞	QNAN		
QNAN	QNAN	QNAN		
SNAN	SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

`Div(x1+i*y1,x2+i*y2) = (x1+i*y1)*(x2-i*y2)/(x2*x2+y2*y2).`

Overflow in a complex function occurs when `x2+i*y2` is not zero, `x1`, `x2`, `y1`, `y2` are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In that case, the function returns ∞ in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW`.

v?Sqrt

Computes a square root of vector elements.

Syntax

```
call vssqrt( n, a, y )
call vssqrti(n, a, inca, y, incy)
call vmssqrt( n, a, y, mode )
call vmssqrti(n, a, inca, y, incy, mode)
call vdsqrt( n, a, y )
call vdsqrti(n, a, inca, y, incy)
call vmdsqrt( n, a, y, mode )
call vmdsqrti(n, a, inca, y, incy, mode)
call vcsqrt( n, a, y )
call vcsqrti(n, a, inca, y, incy)
call vmcsqrt( n, a, y, mode )
call vmcsqrti(n, a, inca, y, incy, mode)
call vzsqrt( n, a, y )
call vzsqrti(n, a, inca, y, incy)
call vmzsqrt( n, a, y, mode )
call vmzsqrti(n, a, inca, y, incy, mode)
```

Include Files

- `mkl_vml.f90`

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdsqrt, vmdsqrt COMPLEX for vcsqrt, vmcsqrt DOUBLE COMPLEX for vzsqrt, vmzsqrt REAL, INTENT(IN) for vssqrt, vmssqrt DOUBLE PRECISION, INTENT(IN) for vdsqrt, vmdsqrt COMPLEX, INTENT(IN) for vcsqrt, vmcsqrt DOUBLE COMPLEX, INTENT(IN) for vzsqrt, vmzsqrt	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	REAL for vssqrt, vmssqrt DOUBLE PRECISION for vdsqrt, vmdsqrt COMPLEX for vcsqrt, vmcsqrt DOUBLE COMPLEX for vzsqrt, vmzsqrt REAL, INTENT(OUT) for vssqrt, vmssqrt DOUBLE PRECISION, INTENT(OUT) for vdsqrt, vmdsqrt COMPLEX, INTENT(OUT) for vcsqrt, vmcsqrt DOUBLE COMPLEX, INTENT(OUT) for vzsqrt, vmzsqrt	Array that specifies the output vector *y*.

Description

The `v?Sqrt` function computes a square root of vector elements.

Special Values for Real Function v?Sqrt(x)

Argument	Result	VM Error Status	Exception
X < +0	QNAN	VML_STATUS_ERRDOM	INVALID
+0	+0		
-0	-0		
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

See Special Value Notations for the conventions used in the table below.

Special Values for Complex Function v?Sqrt(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	+∞+i·∞	+∞+i·∞	+∞+i·∞	+∞+i·∞	+∞+i·∞	+∞+i·∞	+∞+i·∞
+i·Y	+0+i·∞					+∞+i·0	QNAN+i·QNAN
+i·0	+0+i·∞		+0+i·0	+0+i·0		+∞+i·0	QNAN+i·QNAN
-i·0	+0-i·∞		+0-i·0	+0-i·0		+∞-i·0	QNAN+i·QNAN
-i·Y	+0-i·∞					+∞-i·0	QNAN+i·QNAN
-i·∞	+∞-i·∞	+∞-i·∞	+∞-i·∞	+∞-i·∞	+∞-i·∞	+∞-i·∞	+∞-i·∞
+i·NAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	+∞+i·QNAN	QNAN+i·QNAN

Notes:

- raises `INVALID` exception when the real or imaginary part of the argument is `SNAN`
- `Sqrt(CONJ(z))=CONJ(Sqrt(z))`.

v?InvSqrt

Computes an inverse square root of vector elements.

Syntax

```
call vsinvsqrt( n, a, y )
call vsinvsqrti(n, a, inca, y, incy)
call vmsinvsqrt( n, a, y, mode )
call vmsinvsqrti(n, a, inca, y, incy, mode)
call vdinvsqrt( n, a, y )
call vdinvsqrti(n, a, inca, y, incy)
call vmdinvsqrt( n, a, y, mode )
call vmdinvsqrti(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdinvsqrt, vmdinvsqrt REAL, INTENT(IN) for vsinvsqrt, vmsinvsqrt DOUBLE PRECISION, INTENT(IN) for vdinvsqrt, vmdinvsqrt	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdinvsqrt, vmdinvsqrt REAL, INTENT(OUT) for vsinvsqrt, vmsinvsqrt DOUBLE PRECISION, INTENT(OUT) for vdinvsqrt, vmdinvsqrt	Array that specifies the output vector *y*.

Description

The v?InvSqrt function computes an inverse square root of vector elements.

Special Values for Real Function v?InvSqrt(x)

Argument	Result	VM Error Status	Exception
X < +0	QNAN	VML_STATUS_ERRDOM	INVALID
+0	+∞	VML_STATUS_SING	ZERODIVIDE
-0	-∞	VML_STATUS_SING	ZERODIVIDE
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+0		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Cbrt

Computes a cube root of vector elements.

Syntax

```
call vscbrt( n, a, y )
call vscbrti(n, a, inca, y, incy)
call vmscbrt( n, a, y, mode )
call vmscbrti(n, a, inca, y, incy, mode)
call vdcbrt( n, a, y )
call vdcbrti(n, a, inca, y, incy)
call vmdcbrt( n, a, y, mode )
call vmdcbrti(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdcbrt, vmdcbrt REAL, INTENT(IN) for vscbrt, vmscbrt DOUBLE PRECISION, INTENT(IN) for vdcbrt, vmdcbrt	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdcbrt, vmdcbrt REAL, INTENT(OUT) for vscbrt, vmscbrt DOUBLE PRECISION, INTENT(OUT) for vdcbrt, vmdcbrt	Array that specifies the output vector *y*.

Description

The v?Cbrt function computes a cube root of vector elements.

Special Values for Real Function v?Cbrt(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
QNAN	QNAN	
SNAN	QNAN	INVALID

v?InvCbrt

Computes an inverse cube root of vector elements.

Syntax

```
call vsinvcbrt( n, a, y )
call vsinvcbrti(n, a, inca, y, incy)
call vmsinvcbrt( n, a, y, mode )
call vmsinvcbrti(n, a, inca, y, incy, mode)
call vdinvcbrt( n, a, y )
call vdinvcbrti(n, a, inca, y, incy)
call vmdinvcbrt( n, a, y, mode )
call vmdinvcbrti(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdinvcbrt, vmdinvcbrt REAL, INTENT(IN) for vsinvcbrt, vmsinvcbrt DOUBLE PRECISION, INTENT(IN) for vdinvcbrt, vmdinvcbrt	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdinvcbrt, vmdinvcbrt REAL, INTENT(OUT) for vsinvcbrt, vmsinvcbrt DOUBLE PRECISION, INTENT(OUT) for vdinvcbrt, vmdinvcbrt	Array that specifies the output vector *y*.

Description

The v?InvCbrt function computes an inverse cube root of vector elements.

Special Values for Real Function v?InvCbrt(x)

Argument	Result	VM Error Status	Exception
+0	+∞	VML_STATUS_SING	ZERODIVIDE
-0	-∞	VML_STATUS_SING	ZERODIVIDE
+∞	+0		
-∞	-0		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Pow2o3

Computes the cube root of the square of each vector element.

Syntax

```
call vspow2o3( n, a, y )
call vspow2o3i(n, a, inca, y, incy)
call vmspow2o3( n, a, y, mode )
call vmspow2o3i(n, a, inca, y, incy, mode)
call vdpow2o3( n, a, y )
call vdpow2o3i(n, a, inca, y, incy)
call vmdpow2o3( n, a, y, mode )
call vmdpow2o3i(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.

Name	Type	Description
a	DOUBLE PRECISION for vdpow2o3, vmdpow2o3 REAL, INTENT(IN) for vspow2o3, vmspow2o3 DOUBLE PRECISION, INTENT(IN) for vdpow2o3, vmdpow2o3	Arrays, specify the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdpow2o3, vmdpow2o3 REAL, INTENT(OUT) for vspow2o3, vmspow2o3 DOUBLE PRECISION, INTENT(OUT) for vdpow2o3, vmdpow2o3	Array, specifies the output vector *y*.

Description

The v?Pow2o3 function computes the cube root of the square of each vector element.

Special Values for Real Function v?Pow2o3(x)

Argument	Result	Exception
+0	+0	
-0	+0	
+∞	+∞	
-∞	+∞	
QNAN	QNAN	
SNAN	QNAN	INVALID

v?Pow3o2

Computes the square root of the cube of each vector element.

Syntax

```
call vspow3o2( n, a, y )
call vspow3o2i(n, a, inca, y, incy)
call vmspow3o2( n, a, y, mode )
call vmspow3o2i(n, a, inca, y, incy, mode)
call vdpow3o2( n, a, y )
```

```
call vdpow3o2i(n, a, inca, y, incy)
call vmdpow3o2( n, a, y, mode )
call vmdpow3o2i(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdpow3o2, vmdpow3o2 REAL, INTENT(IN) for vspow3o2, vmspow3o2 DOUBLE PRECISION, INTENT(IN) for vdpow3o2, vmdpow3o2	Arrays, specify the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Pow3o2 Function

Data Type	Threshold Limitations on Input Parameters
single precision	abs(*a*[i]) < (FLT_MAX)$^{2/3}$
double precision	abs(*a*[i]) < (DBL_MAX)$^{2/3}$

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdpow3o2, vmdpow3o2 REAL, INTENT(OUT) for vspow3o2, vmspow3o2 DOUBLE PRECISION, INTENT(OUT) for vdpow3o2, vmdpow3o2	Array, specifies the output vector *y*.

Description

The v?Pow3o2 function computes the square root of the cube of each vector element.

Special Values for Real Function v?Pow3o2(x)

Argument	Result	VM Error Status	Exception
X < +0	QNAN	VML_STATUS_ERRDOM	INVALID
+0	+0		
-0	-0		

Argument	Result	VM Error Status	Exception
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Pow

Computes a to the power b for elements of two vectors.

Syntax

```
call vspow( n, a, b, y )
call vspowi(n, a, inca, b, incb, y, incy)
call vmspow( n, a, b, y, mode )
call vmspowi(n, a, inca, b, incb, y, incy, mode)
call vdpow( n, a, b, y )
call vdpowi(n, a, inca, b, incb, y, incy)
call vmdpow( n, a, b, y, mode )
call vmdpowi(n, a, inca, b, incb, y, incy, mode)
call vcpow( n, a, b, y )
call vcpowi(n, a, inca, b, incb, y, incy)
call vmcpow( n, a, b, y, mode )
call vmcpowi(n, a, inca, b, incb, y, incy, mode)
call vzpow( n, a, b, y )
call vzpowi(n, a, inca, b, incb, y, incy)
call vmzpow( n, a, b, y, mode )
call vmzpowi(n, a, inca, b, incb, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a, *b*	DOUBLE PRECISION for vdpow, vmdpow COMPLEX for vcpow, vmcpow DOUBLE COMPLEX for vzpow, vmzpow REAL, INTENT(IN) for vspow, vmspow	Arrays that specify the input vectors *a* and *b*.

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdpow, vmdpow COMPLEX, INTENT(IN) for vcpow, vmcpow DOUBLE COMPLEX, INTENT(IN) for vzpow, vmzpow	
inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Pow Function

Data Type	Threshold Limitations on Input Parameters
single precision	abs(*a*[i]) < (FLT_MAX)$^{1/b[i]}$
double precision	abs(*a*[i]) < (DBL_MAX)$^{1/b[i]}$

Precision overflow thresholds for the complex v?Pow function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdpow, vmdpow COMPLEX for vcpow, vmcpow DOUBLE COMPLEX for vzpow, vmzpow REAL, INTENT(OUT) for vspow, vmspow DOUBLE PRECISION, INTENT(OUT) for vdpow, vmdpow COMPLEX, INTENT(OUT) for vcpow, vmcpow DOUBLE COMPLEX, INTENT(OUT) for vzpow, vmzpow	Array that specifies the output vector *y*.

Description

The v?Pow function computes *a* to the power *b* for elements of two vectors.

The real function v(s/d)Pow has certain limitations on the input range of *a* and *b* parameters. Specifically, if *a*[*i*] is positive, then *b*[*i*] may be arbitrary. For negative *a*[*i*], the value of *b*[*i*] must be an integer (either positive or negative).

The complex function v(c/z)Pow has no input range limitations.

Special values for Real Function v?Pow(x,y)

Argument 1 (X)	Argument 2 (Y)	Result	VM Error Status	Exception

QNAN	QNAN	QNAN		
QNAN	SNAN	QNAN		INVALID
SNAN	QNAN	QNAN		INVALID
SNAN	SNAN	QNAN		INVALID

The complex double precision versions of this function, `vzPow` and `vmzPow`, are implemented in the EP accuracy mode only. If used in HA or LA mode, `vzPow` and `vmzPow` set the VM Error Status to `VML_STATUS_ACCURACYWARNING` (see the Values of the VM Status table).

* Overflow in a real function is supported only in the HA/LA accuracy modes. The overflow occurs when x and y are finite numbers, but the result is too large to fit the target precision. In this case, the function:

1. Returns ∞ in the result.
2. Raises the `OVERFLOW` exception.
3. Sets the VM Error Status to `VML_STATUS_OVERFLOW`.

Overflow in a complex function occurs (supported in the `HA`/`LA` accuracy modes only) when all `RE(x)`, `RE(y)`, `IM(x)`, `IM(y)` arguments are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

v?Powx

Computes vector a to the scalar power b.

Syntax

```
call vspowx( n, a, b, y )
call vspowxi(n, a, inca, b, y, incy)
call vmspowx( n, a, b, y, mode )
call vmspowxi(n, a, inca, b, y, incy, mode)
call vdpowx( n, a, b, y )
call vdpowxi(n, a, inca, b, y, incy)
call vmdpowx( n, a, b, y, mode )
call vmdpowxi(n, a, inca, b, y, incy, mode)
call vcpowx( n, a, b, y )
```

```
call vcpowxi(n, a, inca, b, y, incy)
call vmcpowx( n, a, b, y, mode )
call vmcpowxi(n, a, inca, b, y, incy, mode)
call vzpowx( n, a, b, y )
call vzpowxi(n, a, inca, b, y, incy)
call vmzpowx( n, a, b, y, mode )
call vmzpowxi(n, a, inca, b, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Number of elements to be calculated.
a	DOUBLE PRECISION for vdpowx, vmdpowx COMPLEX for vcpowx, vmcpowx DOUBLE COMPLEX for vzpowx, vmzpowx REAL, INTENT(IN) for vspowx, vmspowx DOUBLE PRECISION, INTENT(IN) for vdpowx, vmdpowx COMPLEX, INTENT(IN) for vcpowx, vmcpowx DOUBLE COMPLEX, INTENT(IN) for vzpowx, vmzpowx	Array *a* that specifies the input vector
b	DOUBLE PRECISION for vdpowx, vmdpowx COMPLEX for vcpowx, vmcpowx DOUBLE COMPLEX for vzpowx, vmzpowx REAL, INTENT(IN) for vspowx, vmspowx DOUBLE PRECISION, INTENT(IN) for vdpowx, vmdpowx COMPLEX, INTENT(IN) for vcpowx, vmcpowx DOUBLE COMPLEX, INTENT(IN) for vzpowx, vmzpowx	Scalar value *b* that is the constant power.

Name	Type	Description
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Powx Function

Data Type	Threshold Limitations on Input Parameters
single precision	abs(*a*[i]) < (FLT_MAX)$^{1/b}$
double precision	abs(*a*[i]) < (DBL_MAX)$^{1/b}$

Precision overflow thresholds for the complex v?Powx function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdpowx, vmdpowx COMPLEX for vcpowx, vmcpowx DOUBLE COMPLEX for vzpowx, vmzpowx REAL, INTENT(OUT) for vspowx, vmspowx DOUBLE PRECISION, INTENT(OUT) for vdpowx, vmdpowx COMPLEX, INTENT(OUT) for vcpowx, vmcpowx DOUBLE COMPLEX, INTENT(OUT) for vzpowx, vmzpowx	Array that specifies the output vector *y*.

Description

The v?Powx function computes *a* to the power *b* for a vector *a* and a scalar *b*.

The real function v(s/d)Powx has certain limitations on the input range of *a* and *b* parameters. Specifically, if *a*[*i*] is positive, then *b* may be arbitrary. For negative *a*[*i*], the value of *b* must be an integer (either positive or negative).

The complex function v(c/z)Powx has no input range limitations.

Special values and VM Error Status treatment are the same as for the v?Pow function.

v?Powr

Computes a to the power b for elements of two vectors, where the elements of vector argument a are all non-negative.

Syntax

```
call vspowr (n, a, b, y )
call vspowri(n, a, inca, b, incb, y, incy)
```

```
call vmspowr (n, a, b, y, mode )
call vmspowri(n, a, inca, b, incb, y, incy, mode)
call vdpowr (n, a, b, y )
call vdpowri(n, a, inca, b, incb, y, incy)
call vmdpowr (n, a, b, y, mode )
call vmdpowri(n, a, inca, b, incb, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER	Specifies the number of elements to be calculated.
a, b	REAL for vsPowr REAL for vmsPowr DOUBLE PRECISION for vdPowr DOUBLE PRECISION for vmdPowr	Pointers to arrays containing the input vectors *a* and *b*.
inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
mode	INTEGER (KIND=8)	Overrides the global VM *mode* setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	REAL for vsPowr REAL for vmsPowr DOUBLE PRECISION for vdPowr DOUBLE PRECISION for vmdPowr	Pointer to an array containing the output vector *y*.

Description

The v?Powr function raises each element of vector *a* by the corresponding element of vector *b*. The elements of *a* are all nonnegative ($a_i \geq 0$).

Precision Overflow Thresholds for Real Function v?Powr

Data Type	Threshold Limitations on Input Parameters
single precision	$a_i < (\text{FLT\_MAX})^{1/b_i}$
double precision	$a_i < (\text{DBL\_MAX})^{1/b_i}$

Special values and VM Error Status treatment for v?Powr function are the same as for v?Pow, unless otherwise indicated in this table:

Special values for Real Function v?Powr(x)

Argument 1	Argument 2	Result	VM Error Status	Exception

See Also

Pow Computes *a* to the power *b* for elements of two vectors.

Powx Computes vector *a* to the scalar power *b*.

v?Hypot

Computes a square root of sum of two squared elements.

Syntax

```
call vshypot( n, a, b, y )
call vshypoti(n, a, inca, b, incb, y, incy)
call vmshypot( n, a, b, y, mode )
call vmshypoti(n, a, inca, b, incb, y, incy, mode)
call vdhypot( n, a, b, y )
call vdhypoti(n, a, inca, b, incb, y, incy)
call vmdhypot( n, a, b, y, mode )
call vmdhypoti(n, a, inca, b, incb, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	`INTEGER, INTENT(IN)`	Number of elements to be calculated.

a, *b*	`DOUBLE PRECISION` for `vdhypot`, `vmdhypot`
	`REAL, INTENT(IN)` for `vshypot`, `vmshypot`
	`DOUBLE PRECISION, INTENT(IN)` for `vdhypot, vmdhypot`
		Arrays that specify the input vectors *a* and *b*

inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
mode	`INTEGER(KIND=8), INTENT(IN)`	Overrides global VM mode setting for this function call. See `vmlSetMode` for possible values and their description.

Precision Overflow Thresholds for Hypot Function

Data Type	Threshold Limitations on Input Parameters
single precision	`abs(a[i]) < sqrt(FLT_MAX)`
	`abs(b[i]) < sqrt(FLT_MAX)`
double precision	`abs(a[i]) < sqrt(DBL_MAX)`
	`abs(b[i]) < sqrt(DBL_MAX)`

Output Parameters

Name	Type	Description

y	`DOUBLE PRECISION` for `vdhypot`, `vmdhypot`
	`REAL, INTENT(OUT)` for `vshypot`, `vmshypot`
	`DOUBLE PRECISION, INTENT(OUT)` for `vdhypot, vmdhypot`
		Array that specifies the output vector *y*.

Description

The function `v?Hypot` computes a square root of sum of two squared elements.

Special values for Real Function v?Hypot(x)

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
-0	-0	+0	
+∞	any value	+∞	
any value	+∞	+∞	
SNAN	any value	QNAN	INVALID

Argument 1	Argument 2	Result	Exception
any value	SNAN	QNAN	INVALID
QNAN	any value	QNAN	
any value	QNAN	QNAN	

Exponential and Logarithmic Functions

v?Exp

Computes an exponential of vector elements.

Syntax

```
call vsexp( n, a, y )
call vsexpi(n, a, inca, y, incy)
call vmsexp( n, a, y, mode )
call vmsexpi(n, a, inca, y, incy, mode)
call vdexp( n, a, y )
call vdexpi(n, a, inca, y, incy)
call vmdexp( n, a, y, mode )
call vmdexpi(n, a, inca, y, incy, mode)
call vcexp( n, a, y )
call vcexpi(n, a, inca, y, incy)
call vmcexp( n, a, y, mode )
call vmcexpi(n, a, inca, y, incy, mode)
call vzexp( n, a, y )
call vzexpi(n, a, inca, y, incy)
call vmzexp( n, a, y, mode )
call vmzexpi(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdexp, vmdexp COMPLEX for vcexp, vmcexp DOUBLE COMPLEX for vzexp, vmzexp REAL, INTENT(IN) for vsexp, vmsexp	Array, specifies the input vector *a*.

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdexp, vmdexp COMPLEX, INTENT(IN) for vcexp, vmcexp DOUBLE COMPLEX, INTENT(IN) for vzexp, vmzexp	
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Exp Function

Data Type	Threshold Limitations on Input Parameters
single precision	*a*[i] < Ln(FLT_MAX)
double precision	*a*[i] < Ln(DBL_MAX)

Precision overflow thresholds for the complex v?Exp function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdexp, vmdexp COMPLEX for vcexp, vmcexp DOUBLE COMPLEX for vzexp, vmzexp REAL, INTENT(OUT) for vsexp, vmsexp DOUBLE PRECISION, INTENT(OUT) for vdexp, vmdexp COMPLEX, INTENT(OUT) for vcexp, vmcexp DOUBLE COMPLEX, INTENT(OUT) for vzexp, vmzexp	Array, specifies the output vector *y*.

Description

The v?Exp function computes an exponential of vector elements.

Special Values for Real Function v?Exp(x)

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
X < underflow	+0	VML_STATUS_UNDERFLOW	UNDERFLOW
+∞	+∞		

Argument	Result	VM Error Status	Exception
-∞	+0		
QNAN	QNAN		
SNAN	QNAN		INVALID

See Special Value Notations for the conventions used in the table below.

Special Values for Complex Function v?Exp(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	+0+i·0	QNAN +i·QNAN INVALID	QNAN +i·QNAN INVALID	QNAN +i·QNAN INVALID	QNAN +i·QNAN INVALID	+∞ +i·QNAN INVALID	QNAN +i·QNAN INVALID
+i·Y	+0·CIS(Y)					+∞·CIS(Y)	QNAN +i·QNAN
+i·0	+0·CIS(0)		+1+i·0	+1+i·0		+∞+i·0	QNAN+i·0
-i·0	+0·CIS(0)		+1-i·0	+1-i·0		+∞-i·0	QNAN-i·0
-i·Y	+0·CIS(Y)					+∞·CIS(Y)	QNAN +i·QNAN
-i·∞	+0-i·0	QNAN +i·QNAN INVALID	QNAN +i·QNAN INVALID	QNAN +i·QNAN INVALID	QNAN +i·QNAN INVALID	+∞ +i·QNAN INVALID	QNAN +i·QNAN INVALID
+i·NAN	+0+i·0	QNAN +i·QNAN INVALID	QNAN +i·QNAN INVALID	QNAN +i·QNAN INVALID	QNAN +i·QNAN INVALID	+∞ +i·QNAN	QNAN +i·QNAN

Notes:

- raises the `INVALID` exception when real or imaginary part of the argument is `SNAN`
- raises the `INVALID` exception on argument `z=-∞+i·QNAN`
- raises the `OVERFLOW` exception and sets the VM Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when both `RE(z)` and `IM(z)` are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.

v?Exp2

Computes the base 2 exponential of vector elements.

Syntax

```
call vsexp2 (n, a, y)
call vsexp2i(n, a, inca, y, incy)
call vmsexp2 (n, a, y, mode)
call vmsexp2i(n, a, inca, y, incy, mode)
call vdexp2 (n, a, y)
call vdexp2i(n, a, inca, y, incy)
call vmdexp2 (n, a, y, mode)
call vmdexp2i(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER	Specifies the number of elements to be calculated.
a	REAL for vsExp2 REAL for vmsExp2 DOUBLE PRECISION for vdExp2 DOUBLE PRECISION for vmdExp2	Pointer to the array containing the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER (KIND=8)	Overrides the global VM *mode* setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	REAL for vsExp2 REAL for vmsExp2 DOUBLE PRECISION for vdExp2 DOUBLE PRECISION for vmdExp2	Pointer to an array containing the output vector *y*.

Description

The v?Exp2 function computes the base 2 exponential of vector elements.

Precision Overflow Thresholds for Real Function v?Exp2

Data Type	Threshold Limitations on Input Parameters
single precision	$a_i < \log_2(\text{FLT\_MAX})$
double precision	$a_i < \log_2(\text{DBL\_MAX})$

See Special Value Notations for the conventions used in this table:

Special values for Real Function v?Exp2(x)

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
x > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
x < underflow	+0	VML_STATUS_UNDERFLOW	UNDERFLOW
+∞	+∞		
-∞	+0		
QNAN	QNAN		
SNAN	QNAN		INVALID

See Also

Exp Computes an exponential of vector elements.
Exp10 Computes the base 10 exponential of vector elements.

v?Exp10

Computes the base 10 exponential of vector elements.

Syntax

```
call vsexp10 (n, a, y)
call vsexp10i(n, a, inca, y, incy)
call vmsexp10 (n, a, y, mode)
call vmsexp10i(n, a, inca, y, incy, mode)
call vdexp10 (n, a, y)
call vdexp10i(n, a, inca, y, incy)
call vmdexp10 (n, a, y, mode)
call vmdexp10i(n, a, inca, y, incy, mode)
```

Input Parameters

Name	Type	Description
n	INTEGER	Specifies the number of elements to be calculated.
a	REAL for vsExp10 REAL for vmsExp10 DOUBLE PRECISION for vdExp10 DOUBLE PRECISION for vmdExp10	Pointer to the array containing the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER (KIND=8)	Overrides the global VM *mode* setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	REAL for vsExp10 REAL for vmsExp10 DOUBLE PRECISION for vdExp10 DOUBLE PRECISION for vmdExp10	Pointer to an array containing the output vector *y*.

Description

The `v?Exp10` function computes the base 10 exponential of vector elements.

Precision Overflow Thresholds for Real Function v?Exp10

Data Type	Threshold Limitations on Input Parameters
single precision	$a_i < \log_{10}(\text{FLT\_MAX})$
double precision	$a_i < \log_{10}(\text{DBL\_MAX})$

See Special Value Notations for the conventions used in this table:

Special values for Real Function v?Pow(x)

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
x > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
x < underflow	+0	VML_STATUS_UNDERFLOW	UNDERFLOW
+∞	+∞		
-∞	+0		
QNAN	QNAN		
SNAN	QNAN		INVALID

See Also

Exp Computes an exponential of vector elements.
Exp2 Computes the base 2 exponential of vector elements.

v?Expm1

Computes an exponential of vector elements decreased by 1.

Syntax

```
call vsexpm1( n, a, y )
call vsexpm1i(n, a, inca, y, incy)
call vmsexpm1( n, a, y, mode )
call vmsexpm1i(n, a, inca, y, incy, mode)
call vdexpm1( n, a, y )
call vdexpm1i(n, a, inca, y, incy)
call vdexpm1( n, a, y, mode )
call vmdexpm1i(n, a, inca, y, incy, mode)
```

Include Files

- `mkl_vml.f90`

Input Parameters

Name	Type	Description
n	`INTEGER, INTENT(IN)`	Specifies the number of elements to be calculated.

Name	Type	Description
a	DOUBLE PRECISION for vdexpm1, vmdexpm1 REAL, INTENT(IN) for vsexpm1, vmsexpm1 DOUBLE PRECISION, INTENT(IN) for vdexpm1, vmdexpm1	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Expm1 Function

Data Type	Threshold Limitations on Input Parameters
single precision	*a*[i] < Ln(FLT_MAX)
double precision	*a*[i] < Ln(DBL_MAX)

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdexpm1, vmdexpm1 REAL, INTENT(OUT) for vsexpm1, vmsexpm1 DOUBLE PRECISION, INTENT(OUT) for vdexpm1, vmdexpm1	Array that specifies the output vector *y*.

Description

The v?Expm1 function computes an exponential of vector elements decreased by 1.

Special Values for Real Function v?Expm1(x)

Argument	Result	VM Error Status	Exception
+0	+0		
-0	+0		
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
+∞	+∞		
-∞	-1		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Ln

Computes natural logarithm of vector elements.

Syntax

```
call vsln( n, a, y )
call vslni(n, a, inca, y, incy)
```

```
call vmsln( n, a, y, mode )
call vmslni(n, a, inca, y, incy, mode)
call vdln( n, a, y )
call vdlni(n, a, inca, y, incy)
call vmdln( n, a, y, mode )
call vmdlni(n, a, inca, y, incy, mode)
call vcln( n, a, y )
call vclni(n, a, inca, y, incy)
call vmcln( n, a, y, mode )
call vmclni(n, a, inca, y, incy, mode)
call vzln( n, a, y )
call vzlni(n, a, inca, y, incy)
call vmzln( n, a, y, mode )
call vmzlni(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdln, vmdln COMPLEX for vcln, vmcln DOUBLE COMPLEX for vzln, vmzln REAL, INTENT(IN) for vsln, vmsln DOUBLE PRECISION, INTENT(IN) for vdln, vmdln COMPLEX, INTENT(IN) for vcln, vmcln DOUBLE COMPLEX, INTENT(IN) for vzln, vmzln	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdln, vmdln COMPLEX for vcln, vmcln DOUBLE COMPLEX for vzln, vmzln REAL, INTENT(OUT) for vsln, vmsln DOUBLE PRECISION, INTENT(OUT) for vdln, vmdln COMPLEX, INTENT(OUT) for vcln, vmcln DOUBLE COMPLEX, INTENT(OUT) for vzln, vmzln	Array that specifies the output vector *y*.

Description

The v?Ln function computes natural logarithm of vector elements.

Special Values for Real Function v?Ln(x)

Argument	Result	VM Error Status	Exception
+1	+0		
X < +0	QNAN	VML_STATUS_ERRDOM	INVALID
+0	-∞	VML_STATUS_SING	ZERODIVIDE
-0	-∞	VML_STATUS_SING	ZERODIVIDE
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

See Special Value Notations for the conventions used in the table below.

Special Values for Complex Function v?Ln(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	$+\infty + i \cdot \frac{3\pi}{4}$	+∞+i·π/2	+∞+i·π/2	+∞+i·π/2	+∞+i·π/2	+∞+i·π/4	+∞+i·QNAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`

v?Log2

Computes the base 2 logarithm of vector elements.

Syntax

```
call vslog2 (n, a, y)
call vslog2i(n, a, inca, y, incy)
call vmslog2 (n, a, y, mode)
call vmslog2i(n, a, inca, y, incy, mode)
call vdlog2 (n, a, y)
call vdlog2i(n, a, inca, y, incy)
call vmdlog2 (n, a, y, mode)
call vmdlog2i(n, a, inca, y, incy, mode)
```

Include Files

- `mkl_vml.f90`

Input Parameters

Name	Type	Description
n	`INTEGER`	Specifies the number of elements to be calculated.
a	`REAL` for `vslog2` `REAL` for `vmslog2`	Pointer to the array containing the input vector *a*.

Name	Type	Description
	DOUBLE PRECISION for vdlog2	
	DOUBLE PRECISION for vmdlog2	
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER (KIND=8)	Overrides the global VM *mode* setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	REAL for vslog2	Pointer to an array containing the output vector *y*.
	REAL for vmslog2	
	DOUBLE PRECISION for vdlog2	
	DOUBLE PRECISION for vmdlog2	

Description

The v?Log2 function computes the base 2 logarithm of vector elements.

See Special Value Notations for the conventions used in this table:

Special values for Real Function v?Log2(x)

Argument	Result	VM Error Status	Exception
+1	+0		
x < +0	QNAN	VML_STATUS_ERRDOM	INVALID

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`

v?Log1p

Computes a natural logarithm of vector elements that are increased by 1.

Syntax

```
call vslog1p( n, a, y )
call vslog1pi(n, a, inca, y, incy)
call vmslog1p( n, a, y, mode )
call vmslog1pi(n, a, inca, y, incy, mode)
call vdlog1p( n, a, y )
call vdlog1pi(n, a, inca, y, incy)
call vmdlog1p( n, a, y, mode )
call vmdlog1pi(n, a, inca, y, incy, mode)
```

Include Files

- `mkl_vml.f90`

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdlog1p, vmdlog1p REAL, INTENT(IN) for vslog1p, vmslog1p DOUBLE PRECISION, INTENT(IN) for vdlog1p, vmdlog1p	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdlog1p, vmdlog1p REAL, INTENT(OUT) for vslog1p, vmslog1p DOUBLE PRECISION, INTENT(OUT) for vdlog1p, vmdlog1p	Array that specifies the output vector *y*.

Description

The v?Log1p function computes a natural logarithm of vector elements that are increased by 1.

Special Values for Real Function v?Log1p(x)

Argument	Result	VM Error Status	Exception
-1	-∞	VML_STATUS_SING	ZERODIVIDE
X < -1	QNAN	VML_STATUS_ERRDOM	INVALID
+0	+0		
-0	-0		
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Logb

Computes the exponents of the elements of input vector a.

Syntax

```
call vslogb (n, a, y)
```

```
call vslogbi(n, a, inca, y, incy)
call vmslogb (n, a, y, mode)
call vmslogbi(n, a, inca, y, incy, mode)
call vdlogb (n, a, y)
call vdlogbi(n, a, inca, y, incy)
call vmdlogb (n, a, y, mode)
call vmdlogbi(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER	Specifies the number of elements to be calculated.
a	REAL for vslogb REAL for vmslogb DOUBLE PRECISION for vdlogb DOUBLE PRECISION for vmdlogb	Pointer to the array containing the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER (KIND=8)	Overrides the global VM *mode* setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	REAL for vslogb REAL for vmslogb DOUBLE PRECISION for vdlogb DOUBLE PRECISION for vmdlogb	Pointer to an array containing the output vector *y*.

Description

The v?Logb function computes the exponents of the elements of the input vector *a*. For each element a_i of vector *a*, this is the integral part of $\log_2|a_i|$. The returned value is exact and is independent of the current rounding direction mode.

See Special Value Notations for the conventions used in this table:

Trigonometric Functions

v?Cos

Computes cosine of vector elements.

Syntax

```
call vscos( n, a, y )
call vscosi(n, a, inca, y, incy)
call vmscos( n, a, y, mode )
call vmscosi(n, a, inca, y, incy, mode)
call vdcos( n, a, y )
call vdcosi(n, a, inca, y, incy)
call vmdcos( n, a, y, mode )
call vmdcosi(n, a, inca, y, incy, mode)
call vccos( n, a, y )
call vccosi(n, a, inca, y, incy)
call vmccos( n, a, y, mode )
call vmccosi(n, a, inca, y, incy, mode)
call vzcos( n, a, y )
call vzcosi(n, a, inca, y, incy)
call vmzcos( n, a, y, mode )
call vmzcosi(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdcos, vmdcos COMPLEX for vccos, vmccos	Array that specifies the input vector *a*.

Name	Type	Description
	DOUBLE PRECISION for vzcos, vmzcos REAL, INTENT(IN) for vscos, vmscos DOUBLE PRECISION, INTENT(IN) for vdcos, vmdcos COMPLEX, INTENT(IN) for vccos, vmccos DOUBLE PRECISION, INTENT(IN) for vzcos, vmzcos	
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdcos, vmdcos COMPLEX for vccos, vmccos DOUBLE PRECISION for vzcos, vmzcos REAL, INTENT(OUT) for vscos, vmscos DOUBLE PRECISION, INTENT(OUT) for vdcos, vmdcos COMPLEX, INTENT(OUT) for vccos, vmccos DOUBLE PRECISION, INTENT(OUT) for vzcos, vmzcos	Array that specifies the output vector *y*.

Description

The v?Cos function computes cosine of vector elements.

Note that arguments abs(*a*[i]) ≤ 2^{13} and abs(*a*[i]) ≤ 2^{16} for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?Cos(x)

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		

Argument	Result	VM Error Status	Exception
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

`Cos(z) = Cosh(i*z).`

Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

Notice revision #20201201

v?Sin

Computes sine of vector elements.

Syntax

```
call vssin( n, a, y )
call vssini(n, a, inca, y, incy)
call vmssin( n, a, y, mode )
call vmssini(n, a, inca, y, incy, mode)
call vdsin( n, a, y )
call vdsini(n, a, inca, y, incy)
call vmdsin( n, a, y, mode )
call vmdsini(n, a, inca, y, incy, mode)
call vcsin( n, a, y )
call vcsini(n, a, inca, y, incy)
call vmcsin( n, a, y, mode )
call vmcsini(n, a, inca, y, incy, mode)
call vzsin( n, a, y )
call vzsini(n, a, inca, y, incy)
call vmzsin( n, a, y, mode )
call vmzsini(n, a, inca, y, incy, mode)
```

Include Files

- `mkl_vml.f90`

Input Parameters

Name	Type	Description
n	`INTEGER, INTENT(IN)`	Specifies the number of elements to be calculated.

Name	Type	Description
a	DOUBLE PRECISION for vdsin, vmdsin COMPLEX for vcsin, vmcsin DOUBLE PRECISION for vzsin, vmzsin REAL, INTENT(IN) for vssin, vmssin DOUBLE PRECISION, INTENT(IN) for vdsin, vmdsin COMPLEX, INTENT(IN) for vcsin, vmcsin DOUBLE PRECISION, INTENT(IN) for vzsin, vmzsin	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdsin, vmdsin COMPLEX for vcsin, vmcsin DOUBLE PRECISION for vzsin, vmzsin REAL, INTENT(OUT) for vssin, vmssin DOUBLE PRECISION, INTENT(OUT) for vdsin, vmdsin COMPLEX, INTENT(OUT) for vcsin, vmcsin DOUBLE PRECISION, INTENT(OUT) for vzsin, vmzsin	Array that specifies the output vector *y*.

Description

The function computes sine of vector elements.

Note that arguments abs(*a*[i]) $\leq 2^{13}$ and abs(*a*[i]) $\leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?Sin(x)

Argument	Result	VM Error Status	Exception

Notice revision #20201201

v?SinCos

Computes sine and cosine of vector elements.

Syntax

```
call vssincos( n, a, y, z )
call vssincosi(n, a, inca, y, incy, z, incz)
call vmssincos( n, a, y, z, mode )
call vmssincosi(n, a, inca, y, incy, z, incz, mode)
call vdsincos( n, a, y, z )
call vdsincosi(n, a, inca, y, incy, z, incz)
call vmdsincos( n, a, y, z, mode )
call vmdsincosi(n, a, inca, y, incy, z, incz, mode)
```

Include Files

- `mkl_vml.f90`

Input Parameters

Name	Type	Description
n	`INTEGER, INTENT(IN)`	Specifies the number of elements to be calculated.

a	`DOUBLE PRECISION` for `vdsincos, vmdsincos`
	`REAL, INTENT(IN)` for `vssincos, vmssincos`
	`DOUBLE PRECISION, INTENT(IN)` for `vdsincos, vmdsincos`
		Array that specifies the input vector *a*.

Name	Type	Description
inca, *incy*, *incz*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *y*, and *z*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y, *z*	DOUBLE PRECISION for vdsincos, vmdsincos REAL, INTENT(OUT) for vssincos, vmssincos DOUBLE PRECISION, INTENT(OUT) for vdsincos, vmdsincos	Arrays that specify the output vectors *y* (for sine values) and *z* (for cosine values).

Description

The function computes sine and cosine of vector elements.

Note that arguments abs(*a*[i]) ≤ 2^{13} and abs(*a*[i]) ≤ 2^{16} for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

Notice revision #20201201

v?CIS

Computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

Syntax

```
call vccis( n, a, y )
call vccisi(n, a, inca, y, incy)
call vmccis( n, a, y, mode )
call vmccisi(n, a, inca, y, incy, mode)
call vzcis( n, a, y )
call vzcisi(n, a, inca, y, incy)
call vmzcis( n, a, y, mode )
call vmzcisi(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vzcis, vmzcis REAL, INTENT(IN) for vccis, vmccis DOUBLE PRECISION, INTENT(IN) for vzcis, vmzcis	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE COMPLEX for vzcis, vmzcis COMPLEX, INTENT(OUT) for vccis, vmccis DOUBLE COMPLEX, INTENT(OUT) for vzcis, vmzcis	Array that specifies the output vector *y*.

Description

The v?CIS function computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

See Special Value Notations for the conventions used in the table below.

Special Values for Complex Function v?CIS(x)

x	CIS(x)
+ ∞	QNAN+i·QNAN INVALID
+ 0	+1+i·0
- 0	+1-i·0
- ∞	QNAN+i·QNAN INVALID
NAN	QNAN+i·QNAN

Notes:

- raises `INVALID` exception when the argument is `SNAN`
- raises `INVALID` exception and sets the VM Error Status to `VML_STATUS_ERRDOM` for `x=+∞`, `x=-∞`

v?Tan

Computes tangent of vector elements.

Syntax

```
call vstan( n, a, y )
call vstani(n, a, inca, y, incy)
call vmstan( n, a, y, mode )
call vmstani(n, a, inca, y, incy, mode)
call vdtan( n, a, y )
call vdtani(n, a, inca, y, incy)
call vmdtan( n, a, y, mode )
call vmdtani(n, a, inca, y, incy, mode)
call vctan( n, a, y )
call vctani(n, a, inca, y, incy)
call vmctan( n, a, y, mode )
call vmctani(n, a, inca, y, incy, mode)
call vztan( n, a, y )
call vztani(n, a, inca, y, incy)
call vmztan( n, a, y, mode )
call vmztani(n, a, inca, y, incy, mode)
```

Include Files

- `mkl_vml.f90`

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdtan, vmdtan COMPLEX for vctan, vmctan DOUBLE COMPLEX for vztan, vmztan REAL, INTENT(IN) for vstan, vmstan DOUBLE PRECISION, INTENT(IN) for vdtan, vmdtan COMPLEX, INTENT(IN) for vctan, vmctan DOUBLE COMPLEX, INTENT(IN) for vztan, vmztan	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdtan, vmdtan COMPLEX for vctan, vmctan DOUBLE COMPLEX for vztan, vmztan REAL, INTENT(OUT) for vstan, vmstan DOUBLE PRECISION, INTENT(OUT) for vdtan, vmdtan COMPLEX, INTENT(OUT) for vctan, vmctan DOUBLE COMPLEX, INTENT(OUT) for vztan, vmztan	Array that specifies the output vector *y*.

Description

The v?Tan function computes tangent of vector elements.

Note that arguments abs(a[i]) ≤ 2^{13} and abs(a[i]) ≤ 2^{16} for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?Tan(x)

Argument	Result	VM Error Status	Exception
+0	+0		
-0	-0		
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula Tan(z) = –i*Tanh(i*z).

Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

Notice revision #20201201

v?Acos

Computes inverse cosine of vector elements.

Syntax

```
call vsacos( n, a, y )
call vsacosi(n, a, inca, y, incy)
call vmsacos( n, a, y, mode )
call vmsacosi(n, a, inca, y, incy, mode)
call vdacos( n, a, y )
call vdacosi(n, a, inca, y, incy)
call vmdacos( n, a, y, mode )
call vmdacosi(n, a, inca, y, incy, mode)
call vcacos( n, a, y )
call vcacosi(n, a, inca, y, incy)
call vmcacos( n, a, y, mode )
call vmcacosi(n, a, inca, y, incy, mode)
call vzacos( n, a, y )
call vzacosi(n, a, inca, y, incy)
call vmzacos( n, a, y, mode )
call vmzacosi(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdacos, vmdacos COMPLEX for vcacos, vmcacos DOUBLE COMPLEX for vzacos, vmzacos REAL, INTENT(IN) for vsacos, vmsacos DOUBLE PRECISION, INTENT(IN) for vdacos, vmdacos COMPLEX, INTENT(IN) for vcacos, vmcacos DOUBLE COMPLEX, INTENT(IN) for vzacos, vmzacos	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdacos, vmdacos COMPLEX for vcacos, vmcacos DOUBLE COMPLEX for vzacos, vmzacos REAL, INTENT(OUT) for vsacos, vmsacos DOUBLE PRECISION, INTENT(OUT) for vdacos, vmdacos COMPLEX, INTENT(OUT) for vcacos, vmcacos DOUBLE COMPLEX, INTENT(OUT) for vzacos, vmzacos	Array that specifies the output vector *y*.

Description

The `v?Acos` function computes inverse cosine of vector elements.

Special Values for Real Function v?Acos(x)

Argument	Result	VM Error Status	Exception
+0	+π/2		
-0	+π/2		
+1	+0		
-1	+π		
|X| > 1	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

See Special Value Notations for the conventions used in the table below.

Special Values for Complex Function v?Acos(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	+3·π/4-i·∞	+π/2-i·∞	+π/2-i·∞	+π/2-i·∞	+π/2-i·∞	+π/4-i·∞	QNAN-i·∞
+i·Y	+π-i·∞					+0-i·∞	QNAN +i·QNAN
+i·0	+π-i·∞		+π/2-i·0	+π/2-i·0		+0-i·∞	QNAN +i·QNAN
-i·0	+π+i·∞		+π/2+i·0	+π/2+i·0		+0+i·∞	QNAN +i·QNAN
-i·Y	+π+i·∞					+0+i·∞	QNAN +i·QNAN
-i·∞	+3π/4+i·∞	+π/2+i·∞	+π/2+i·∞	+π/2+i·∞	+π/2+i·∞	+π/4+i·∞	QNAN+i·∞
+i·NAN	QNAN+i·∞	QNAN +i·QNAN	+π/ 2+i·QNAN	+π/ 2+i·QNAN	QNAN +i·QNAN	QNAN+i·∞	QNAN +i·QNAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- `Acos(CONJ(z))=CONJ(Acos(z))`.

v?Asin

Computes inverse sine of vector elements.

Syntax

```
call vsasin( n, a, y )
call vsasini(n, a, inca, y, incy)
call vmsasin( n, a, y, mode )
call vmsasini(n, a, inca, y, incy, mode)
call vdasin( n, a, y )
call vdasini(n, a, inca, y, incy)
```

```
call vmdasin( n, a, y, mode )
call vmdasini(n, a, inca, y, incy, mode)
call vcasin( n, a, y )
call vcasini(n, a, inca, y, incy)
call vmcasin( n, a, y, mode )
call vmcasini(n, a, inca, y, incy, mode)
call vzasin( n, a, y )
call vzasini(n, a, inca, y, incy)
call vmzasin( n, a, y, mode )
call vmzasini(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdasin, vmdasin COMPLEX for vcasin, vmcasin DOUBLE COMPLEX for vzasin, vmzasin REAL, INTENT(IN) for vsasin, vmsasin DOUBLE PRECISION, INTENT(IN) for vdasin, vmdasin COMPLEX, INTENT(IN) for vcasin, vmcasin DOUBLE COMPLEX, INTENT(IN) for vzasin, vmzasin	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdasin, vmdasin	Array that specifies the output vector *y*.

Name	Type	Description
	`COMPLEX` for `vcasin`, `vmcasin`	
	`DOUBLE COMPLEX` for `vzasin`, `vmzasin`	
	`REAL`, `INTENT(OUT)` for `vsasin`, `vmsasin`	
	`DOUBLE PRECISION`, `INTENT(OUT)` for `vdasin`, `vmdasin`	
	`COMPLEX`, `INTENT(OUT)` for `vcasin`, `vmcasin`	
	`DOUBLE COMPLEX`, `INTENT(OUT)` for `vzasin`, `vmzasin`	

Description

The `v?Asin` function computes inverse sine of vector elements.

Special Values for Real Function v?Asin(x)

Argument	Result	VM Error Status	Exception
+0	+0		
-0	-0		
+1	+π/2		
-1	-π/2		
|X| > 1	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

`Asin(z) = -i*Asinh(i*z).`

v?Atan

Computes inverse tangent of vector elements.

Syntax

```
call vsatan( n, a, y )
call vsatani(n, a, inca, y, incy)
call vmsatan( n, a, y, mode )
call vmsatani(n, a, inca, y, incy, mode)
call vdatan( n, a, y )
call vdatani(n, a, inca, y, incy)
call vmdatan( n, a, y, mode )
call vmdatani(n, a, inca, y, incy, mode)
call vcatan( n, a, y )
```

```
call vcatani(n, a, inca, y, incy)
call vmcatan( n, a, y, mode )
call vmcatani(n, a, inca, y, incy, mode)
call vzatan( n, a, y )
call vzatani(n, a, inca, y, incy)
call vmzatan( n, a, y, mode )
call vmzatani(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdatan, vmdatan COMPLEX for vcatan, vmcatan DOUBLE COMPLEX for vzatan, vmzatan REAL, INTENT(IN) for vsatan, vmsatan DOUBLE PRECISION, INTENT(IN) for vdatan, vmdatan COMPLEX, INTENT(IN) for vcatan, vmcatan DOUBLE COMPLEX, INTENT(IN) for vzatan, vmzatan	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdatan, vmdatan COMPLEX for vcatan, vmcatan DOUBLE COMPLEX for vzatan, vmzatan	Array that specifies the output vector *y*.

Name	Type	Description
	`REAL, INTENT(OUT)` for `vsatan, vmsatan`	
	`DOUBLE PRECISION, INTENT(OUT)` for `vdatan, vmdatan`	
	`COMPLEX, INTENT(OUT)` for `vcatan, vmcatan`	
	`DOUBLE COMPLEX, INTENT(OUT)` for `vzatan, vmzatan`	

Description

The `v?Atan` function computes inverse tangent of vector elements.

Special Values for Real Function v?Atan(x)

Argument	Result	VM Error Status	Exception
+0	+0		
-0	-0		
+∞	+π/2		
-∞	-π/2		
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

`Atan(z) = -i*Atanh(i*z).`

v?Atan2

Computes four-quadrant inverse tangent of elements of two vectors.

Syntax

```
call vsatan2( n, a, b, y )
call vsatan2i(n, a, inca, b, incb, y, incy)
call vmsatan2( n, a, b, y, mode )
call vmsatan2i(n, a, inca, b, incb, y, incy, mode)
call vdatan2( n, a, b, y )
call vdatan2i(n, a, inca, b, incb, y, incy)
call vmdatan2( n, a, b, y, mode )
call vmdatan2i(n, a, inca, b, incb, y, incy, mode)
```

Include Files

- `mkl_vml.f90`

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a, *b*	DOUBLE PRECISION for vdatan2, vmdatan2 REAL, INTENT(IN) for vsatan2, vmsatan2 DOUBLE PRECISION, INTENT(IN) for vdatan2, vmdatan2	Arrays that specify the input vectors *a* and *b*.
inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdatan2, vmdatan2 REAL, INTENT(OUT) for vsatan2, vmsatan2 DOUBLE PRECISION, INTENT(OUT) for vdatan2, vmdatan2	Array that specifies the output vector *y*.

Description

The v?Atan2 function computes four-quadrant inverse tangent of elements of two vectors.

The elements of the output vector*y* are computed as the four-quadrant arctangent of *a[i] / b[i]*.

v?Cospi

Computes the cosine of vector elements multiplied by π.

Syntax

```
call vscospi (n, a, y)
call vscospii(n, a, inca, y, incy)
call vmscospi (n, a, y, mode)
call vmscospii(n, a, inca, y, incy, mode)
call vdcospi (n, a, y)
call vdcospii(n, a, inca, y, incy)
call vmdcospi (n, a, y, mode)
call vmdcospii(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER	Specifies the number of elements to be calculated.
a	REAL for vscospi REAL for vmscospi DOUBLE PRECISION for vdcospi DOUBLE PRECISION for vmdcospi	Pointer to the array containing the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER (KIND=8)	Overrides the global VM *mode* setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	REAL for vscospi REAL for vmscospi DOUBLE PRECISION for vdcospi DOUBLE PRECISION for vmdcospi	Pointer to an array containing the output vector *y*.

Description

The v?Cospi function computes the cosine of vector elements multiplied by *π*. For an argument *x*, the function computes cos(*π***x*).

Special values for Real Function v?Cospi(x)

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
n + 0.5, for any integer *n* where *n* + 0.5 is representable	+0		
±∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Application Notes

If arguments abs(a_i) ≤ 2^{22} for single precision or abs(a_i) ≤ 2^{43} for double precision, they belong to the *fast computational path*: arguments for which VM provides the best possible performance. Avoid arguments with do not belong to the fast computational path in VM High Accuracy (HA) or Low Accuracy (LA) functions. For arguments which do not belong to the fast computational path you can use VM Enhanced Performance (EP) functions, which are fast on the entire function domain. However, these functions provide lower accuracy.

See Also

Cos Computes cosine of vector elements.

Cosd Computes the cosine of vector elements multiplied by *π*/180.

v?Sinpi

Computes the sine of vector elements multiplied by π.

Syntax

```
call vssinpi (n, a, y)
call vssinpii(n, a, inca, y, incy)
call vmssinpi (n, a, y, mode)
call vmssinpii(n, a, inca, y, incy, mode)
call vdsinpi (n, a, y)
call vdsinpii(n, a, inca, y, incy)
call vmdsinpi (n, a, y, mode)
call vmdsinpii(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER	Specifies the number of elements to be calculated.
a	REAL for vssinpi REAL for vmssinpi DOUBLE PRECISION for vdsinpi DOUBLE PRECISION for vmdsinpi	Pointer to the array containing the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER (KIND=8)	Overrides the global VM *mode* setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description

y	`REAL` for `vssinpi`
	`REAL` for `vmssinpi`
	`DOUBLE PRECISION` for `vdsinpi`
	`DOUBLE PRECISION` for `vmdsinpi`
		Pointer to an array containing the output vector *y*.

Description

The `v?Sinpi` function computes the sine of vector elements multiplied by *π*. For an argument *x*, the function computes sin(*π***x*).

Special values for Real Function v?Sinpi(x)

Argument	Result	VM Error Status	Exception
+0	+0		
-0	-0		
+*n*, positive integer	+0		
-*n*, negative integer	-0		
±∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Application Notes

If arguments abs(a_i) ≤ 2^{22} for single precision or abs(a_i) ≤ 2^{51} for double precision, they belong to the *fast computational path*: arguments for which VM provides the best possible performance. Avoid arguments with do not belong to the fast computational path in VM High Accuracy (HA) or Low Accuracy (LA) functions. For arguments which do not belong to the fast computational path you can use VM Enhanced Performance (EP) functions, which are fast on the entire function domain. However, these functions provide lower accuracy.

Sin Computes sine of vector elements.

Sind Computes the sine of vector elements multiplied by *π*/180.

v?Tanpi

Computes the tangent of vector elements multiplied by π.

Syntax

```
call vstanpi (n, a, y)
call vstanpii(n, a, inca, y, incy)
call vmstanpi (n, a, y, mode)
call vmstanpii(n, a, inca, y, incy, mode)
call vdtanpi (n, a, y)
call vdtanpii(n, a, inca, y, incy)
call vmdtanpi (n, a, y, mode)
call vmdtanpii(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER	Specifies the number of elements to be calculated.
a	REAL for vstanpi REAL for vmstanpi DOUBLE PRECISION for vdtanpi DOUBLE PRECISION for vmdtanpi	Pointer to the array containing the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER (KIND=8)	Overrides the global VM *mode* setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	REAL for vstanpi REAL for vmstanpi DOUBLE PRECISION for vdtanpi DOUBLE PRECISION for vmdtanpi	Pointer to an array containing the output vector *y*.

Description

The v?Tanpi function computes the tangent of vector elements multiplied by π. For an argument x, the function computes $\tan(\pi * x)$.

Special values for Real Function v?Tanpi(x)

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
±∞	QNAN	VML_STATUS_ERRDOM	INVALID
n, even integer	copysign(0.0, *n*)		
n, odd integer	copysign(0.0, -*n*)		
n + 0.5, for *n* even integer and *n* + 0.5 representable	+∞		
n + 0.5, for *n* odd integer and *n* + 0.5 representable	-∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

The copysign(x, y) function returns the first vector argument x with the sign changed to match that of the second argument y.

Application Notes

If arguments abs(a_i) ≤ 2^{13} for single precision or abs(a_i) ≤ 2^{67} for double precision, they belong to the *fast computational path*: arguments for which VM provides the best possible performance. Avoid arguments with do not belong to the fast computational path in VM High Accuracy (HA) or Low Accuracy (LA) functions. For arguments which do not belong to the fast computational path you can use VM Enhanced Performance (EP) functions, which are fast on the entire function domain. However, these functions provide lower accuracy.

Atan2 Computes four-quadrant inverse tangent of elements of two vectors.

v?Cosd

Computes the cosine of vector elements multiplied by π/180.

Syntax

```
call vscosd (n, a, y)
call vscosdi(n, a, inca, y, incy)
call vmscosd (n, a, y, mode)
call vmscosdi(n, a, inca, y, incy, mode)
call vdcosd (n, a, y)
call vdcosdi(n, a, inca, y, incy)
call vmdcosd (n, a, y, mode)
call vmdcosdi(n, a, inca, y, incy, mode)
```

Include Files

- `mkl_vml.f90`

Input Parameters

Name	Type	Description
n	`INTEGER`	Specifies the number of elements to be calculated.

a	`REAL` for `vscosd`
	`REAL` for `vmscosd`
	`DOUBLE PRECISION` for `vdcosd`
	`DOUBLE PRECISION` for `vmdcosd`
		Pointer to the array containing the input vector *a*.

inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.

Name	Type	Description
mode	`INTEGER (KIND=8)`	Overrides the global VM *mode* setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description

y	`REAL` for `vscosd`
	`REAL` for `vmscosd`
	`DOUBLE PRECISION` for `vdcosd`
	`DOUBLE PRECISION` for `vmdcosd`
		Pointer to an array containing the output vector *y*.

Description

The `v?Cosd` function computes the cosine of vector elements multiplied by $\pi/180$. For an argument x, the function computes $\cos(\pi * x/180)$.

Special values for Real Function v?Cosd(x)

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
±∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Application Notes

If arguments $\text{abs}(a_i) \le 2^{24}$ for single precision or $\text{abs}(a_i) \le 2^{52}$ for double precision, they belong to the *fast computational path*: arguments for which VM provides the best possible performance. Avoid arguments with do not belong to the fast computational path in VM High Accuracy (HA) or Low Accuracy (LA) functions. For arguments which do not belong to the fast computational path you can use VM Enhanced Performance (EP) functions, which are fast on the entire function domain. However, these functions provide lower accuracy.

call vmzcoshi(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdcosh, vmdcosh COMPLEX for vccosh, vmccosh DOUBLE COMPLEX for vzcosh, vmzcosh REAL, INTENT(IN) for vscosh, vmscosh DOUBLE PRECISION, INTENT(IN) for vdcosh, vmdcosh COMPLEX, INTENT(IN) for vccosh, vmccosh DOUBLE COMPLEX, INTENT(IN) for vzcosh, vmzcosh	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Cosh Function

Data Type	Threshold Limitations on Input Parameters
single precision	-Ln(FLT_MAX)-Ln2 <*a*[i] < Ln(FLT_MAX)+Ln2
double precision	-Ln(DBL_MAX)-Ln2 <*a*[i] < Ln(DBL_MAX)+Ln2

Precision overflow thresholds for the complex v?Cosh function are beyond the scope of this document.

Output Parameters

Name	Type	Description

y	`DOUBLE PRECISION` for `vdcosh`, `vmdcosh`
	`COMPLEX` for `vccosh`, `vmccosh`
	`DOUBLE COMPLEX` for `vzcosh`, `vmzcosh`
	`REAL, INTENT(OUT)` for `vscosh`, `vmscosh`
	`DOUBLE PRECISION, INTENT(OUT)` for `vdcosh`, `vmdcosh`
	`COMPLEX, INTENT(OUT)` for `vccosh`, `vmccosh`
	`DOUBLE COMPLEX, INTENT(OUT)` for `vzcosh`, `vmzcosh`
		Array that specifies the output vector *y*.

Description

The `v?Cosh` function computes hyperbolic cosine of vector elements.

Special Values for Complex Function v?Cosh(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	+∞ +i·QNAN INVALID	QNAN +i·QNAN INVALID	QNAN-i·0 INVALID	QNAN+i·0 INVALID	QNAN +i·QNAN INVALID	+∞ +i·QNAN INVALID	QNAN +i·QNAN
+i·Y	+∞·Cos(Y)- i·∞·Sin(Y)					+∞·CIS(Y)	QNAN +i·QNAN
+i·0	+∞-i·0		+1-i·0	+1+i·0		+∞+i·0	QNAN+i·0
-i·0	+∞+i·0		+1+i·0	+1-i·0		+∞-i·0	QNAN-i·0

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
-i·Y	+∞·Cos(Y)- i·∞·Sin(Y)					+∞·CIS(Y)	QNAN +i·QNAN
-i·∞	+∞ +i·QNAN INVALID	QNAN +i·QNAN INVALID	QNAN+i·0 INVALID	QNAN-i·0 INVALID	QNAN +i·QNAN INVALID	+∞ +i·QNAN INVALID	QNAN +i·QNAN
+i·NAN	+∞ +i·QNAN	QNAN +i·QNAN	QNAN +i·QNAN	QNAN- i·QNAN	QNAN +i·QNAN	+∞ +i·QNAN	QNAN +i·QNAN

Notes:

- raises the `INVALID` exception when the real or imaginary part of the argument is `SNAN`
- raises the `OVERFLOW` exception and sets the VM Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when `RE(z), IM(z)` are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- `Cosh(CONJ(z))=CONJ(Cosh(z))`
- `Cosh(-z)=Cosh(z).`

v?Sinh

Computes hyperbolic sine of vector elements.

Syntax

```
call vssinh( n, a, y )
call vssinhi(n, a, inca, y, incy)
call vmssinh( n, a, y, mode )
call vmssinhi(n, a, inca, y, incy, mode)
call vdsinh( n, a, y )
call vdsinhi(n, a, inca, y, incy)
call vmdsinh( n, a, y, mode )
call vmdsinhi(n, a, inca, y, incy, mode)
call vcsinh( n, a, y )
call vcsinhi(n, a, inca, y, incy)
call vmcsinh( n, a, y, mode )
call vmcsinhi(n, a, inca, y, incy, mode)
call vzsinh( n, a, y )
call vzsinhi(n, a, inca, y, incy)
call vmzsinh( n, a, y, mode )
call vmzsinhi(n, a, inca, y, incy, mode)
```

Include Files

- `mkl_vml.f90`

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdsinh, vmdsinh COMPLEX for vcsinh, vmcsinh DOUBLE COMPLEX for vzsinh, vmzsinh REAL, INTENT(IN) for vssinh, vmssinh DOUBLE PRECISION, INTENT(IN) for vdsinh, vmdsinh COMPLEX, INTENT(IN) for vcsinh, vmcsinh DOUBLE COMPLEX, INTENT(IN) for vzsinh, vmzsinh	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Sinh Function

Data Type	Threshold Limitations on Input Parameters
single precision	-Ln(FLT_MAX)-Ln2 <*a*[i] < Ln(FLT_MAX)+Ln2
double precision	-Ln(DBL_MAX)-Ln2 <*a*[i] < Ln(DBL_MAX)+Ln2

Precision overflow thresholds for the complex v?Sinh function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdsinh, vmdsinh COMPLEX for vcsinh, vmcsinh DOUBLE COMPLEX for vzsinh, vmzsinh REAL, INTENT(OUT) for vssinh, vmssinh DOUBLE PRECISION, INTENT(OUT) for vdsinh, vmdsinh COMPLEX, INTENT(OUT) for vcsinh, vmcsinh	Array that specifies the output vector *y*.

Name	Type	Description
	DOUBLE COMPLEX, INTENT(OUT) for vzsinh, vmzsinh	

Description

The v?Sinh function computes hyperbolic sine of vector elements.

Special Values for Real Function v?Sinh(x)

Argument	Result	VM Error Status	Exception
+0	+0		
-0	-0		
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
X < -overflow	-∞	VML_STATUS_OVERFLOW	OVERFLOW
+∞	+∞		
-∞	-∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

See Special Value Notations for the conventions used in the table below.

Special Values for Complex Function v?Sinh(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	-∞+i·QNAN INVALID	QNAN +i·QNAN INVALID	-0+i·QNAN INVALID	+0+i·QNAN INVALID	QNAN +i·QNAN INVALID	+∞ +i·QNAN INVALID	QNAN +i·QNAN

-i·Y	-∞·Cos(Y)+ i·∞·Sin(Y)					+∞·CIS(Y)	QNAN +i·QNAN
-i·∞	-∞+i·QNAN INVALID	QNAN +i·QNAN INVALID	-0+i·QNAN INVALID	+0+i·QNAN INVALID	QNAN +i·QNAN INVALID	+∞ +i·QNAN INVALID	QNAN +i·QNAN
+i·NAN	-∞+i·QNAN	QNAN +i·QNAN	-0+i·QNAN	+0+i·QNAN	QNAN +i·QNAN	+∞ +i·QNAN	QNAN +i·QNAN

Notes:

- raises the INVALID exception when the real or imaginary part of the argument is SNAN
- raises the OVERFLOW exception and sets the VM Error Status to VML_STATUS_OVERFLOW in the case of overflow, that is, when RE(z), IM(z) are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- Sinh(CONJ(z))=CONJ(Sinh(z))
- Sinh(-z)=-Sinh(z).

v?Tanh

Computes hyperbolic tangent of vector elements.

Syntax

```
call vstanh( n, a, y )
call vstanhi(n, a, inca, y, incy)
call vmstanh( n, a, y, mode )
call vmstanhi(n, a, inca, y, incy, mode)
call vdtanh( n, a, y )
call vdtanhi(n, a, inca, y, incy)
call vmdtanh( n, a, y, mode )
call vmdtanhi(n, a, inca, y, incy, mode)
call vctanh( n, a, y )
call vctanhi(n, a, inca, y, incy)
call vmctanh( n, a, y, mode )
call vmctanhi(n, a, inca, y, incy, mode)
call vztanh( n, a, y )
call vztanhi(n, a, inca, y, incy)
call vmztanh( n, a, y, mode )
call vmztanhi(n, a, inca, y, incy, mode)
```

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdtanh, vmdtanh COMPLEX for vctanh, vmctanh DOUBLE COMPLEX for vztanh, vmztanh REAL, INTENT(IN) for vstanh, vmstanh DOUBLE PRECISION, INTENT(IN) for vdtanh, vmdtanh COMPLEX, INTENT(IN) for vctanh, vmctanh	Array that specifies the input vector *a*.

Name	Type	Description
	DOUBLE COMPLEX, INTENT(IN) for vztanh, vmztanh	
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdtanh, vmdtanh COMPLEX for vctanh, vmctanh DOUBLE COMPLEX for vztanh, vmztanh REAL, INTENT(OUT) for vstanh, vmstanh DOUBLE PRECISION, INTENT(OUT) for vdtanh, vmdtanh COMPLEX, INTENT(OUT) for vctanh, vmctanh DOUBLE COMPLEX, INTENT(OUT) for vztanh, vmztanh	Array that specifies the output vector *y*.

Description

The v?Tanh function computes hyperbolic tangent of vector elements.

Special Values for Real Function v?Tanh(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+1	
-∞	-1	
QNAN	QNAN	
SNAN	QNAN	INVALID

See Special Value Notations for the conventions used in the table below.

Special Values for Complex Function v?Tanh(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	-1+i·0	QNAN +i·QNAN INVALID	QNAN +i·QNAN INVALID	QNAN +i·QNAN INVALID	QNAN +i·QNAN INVALID	+1+i·0	QNAN +i·QNAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- `Tanh(CONJ(z))=CONJ(Tanh(z))`
- `Tanh(-z)=-Tanh(z)`.

v?Acosh

Computes inverse hyperbolic cosine (nonnegative) of vector elements.

Syntax

```
call vsacosh( n, a, y )
call vsacoshi(n, a, inca, y, incy)
call vmsacosh( n, a, y, mode )
call vmsacoshi(n, a, inca, y, incy, mode)
call vdacosh( n, a, y )
call vdacoshi(n, a, inca, y, incy)
call vmdacosh( n, a, y, mode )
call vmdacoshi(n, a, inca, y, incy, mode)
call vcacosh( n, a, y )
call vcacoshi(n, a, inca, y, incy)
call vmcacosh( n, a, y, mode )
call vmcacoshi(n, a, inca, y, incy, mode)
call vzacosh( n, a, y )
call vzacoshi(n, a, inca, y, incy)
call vmzacosh( n, a, y, mode )
call vmzacoshi(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdacosh, vmdacosh COMPLEX for vcacosh, vmcacosh DOUBLE COMPLEX for vzacosh, vmzacosh REAL, INTENT(IN) for vsacosh, vmsacosh DOUBLE PRECISION, INTENT(IN) for vdacosh, vmdacosh COMPLEX, INTENT(IN) for vcacosh, vmcacosh DOUBLE COMPLEX, INTENT(IN) for vzacosh, vmzacosh	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdacosh, vmdacosh COMPLEX for vcacosh, vmcacosh DOUBLE COMPLEX for vzacosh, vmzacosh REAL, INTENT(OUT) for vsacosh, vmsacosh DOUBLE PRECISION, INTENT(OUT) for vdacosh, vmdacosh COMPLEX, INTENT(OUT) for vcacosh, vmcacosh DOUBLE COMPLEX, INTENT(OUT) for vzacosh, vmzacosh	Array that specifies the output vector *y*.

Description

The `v?Acosh` function computes inverse hyperbolic cosine (nonnegative) of vector elements.

Special Values for Real Function v?Acosh(x)

Argument	Result	VM Error Status	Exception
+1	+0		
X < +1	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

See Special Value Notations for the conventions used in the table below.

Special Values for Complex Function v?Acosh(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	$+\infty + i \cdot \frac{3\pi}{4}$	+∞+i·π/2	+∞+i·π/2	+∞+i·π/2	+∞+i·π/2	+∞+i·π/4	+∞+i·QNAN
+i·Y	+∞+i·π					+∞+i·0	QNAN +i·QNAN

+i·NAN	+∞ +i·QNAN	QNAN +i·QNAN	QNAN +i·QNAN	QNAN +i·QNAN	QNAN +i·QNAN	+∞ +i·QNAN	QNAN +i·QNAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- `Acosh(CONJ(z))=CONJ(Acosh(z))`.

v?Asinh

Computes inverse hyperbolic sine of vector elements.

Syntax

```
call vsasinh( n, a, y )
call vsasinhi(n, a, inca, y, incy)
call vmsasinh( n, a, y, mode )
```

```
call vmsasinhi(n, a, inca, y, incy, mode)
call vdasinh( n, a, y )
call vdasinhi(n, a, inca, y, incy)
call vmdasinh( n, a, y, mode )
call vmdasinhi(n, a, inca, y, incy, mode)
call vcasinh( n, a, y )
call vcasinhi(n, a, inca, y, incy)
call vmcasinh( n, a, y, mode )
call vmcasinhi(n, a, inca, y, incy, mode)
call vzasinh( n, a, y )

- `Asinh(CONJ(z))=CONJ(Asinh(z))`
- `Asinh(-z)=-Asinh(z)`.

v?Atanh

Computes inverse hyperbolic tangent of vector elements.

Syntax

```
call vsatanh( n, a, y )
call vsatanhi(n, a, inca, y, incy)
call vmsatanh( n, a, y, mode )
call vmsatanhi(n, a, inca, y, incy, mode)
call vdatanh( n, a, y )
call vdatanhi(n, a, inca, y, incy)
call vmdatanh( n, a, y, mode )
call vmdatanhi(n, a, inca, y, incy, mode)
call vcatanh( n, a, y )
call vcatanhi(n, a, inca, y, incy)
call vmcatanh( n, a, y, mode )
call vmcatanhi(n, a, inca, y, incy, mode)
call vzatanh( n, a, y )
call vzatanhi(n, a, inca, y, incy)
call vmzatanh( n, a, y, mode )
call vmzatanhi(n, a, inca, y, incy, mode)
```

Include Files

- `mkl_vml.f90`

Input Parameters

Name	Type	Description
n	`INTEGER, INTENT(IN)`	Specifies the number of elements to be calculated.

Name	Type	Description
a	DOUBLE PRECISION for vdatanh, vmdatanh COMPLEX for vcatanh, vmcatanh DOUBLE COMPLEX for vzatanh, vmzatanh REAL, INTENT(IN) for vsatanh, vmsatanh DOUBLE PRECISION, INTENT(IN) for vdatanh, vmdatanh COMPLEX, INTENT(IN) for vcatanh, vmcatanh DOUBLE COMPLEX, INTENT(IN) for vzatanh, vmzatanh	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdatanh, vmdatanh COMPLEX for vcatanh, vmcatanh DOUBLE COMPLEX for vzatanh, vmzatanh REAL, INTENT(OUT) for vsatanh, vmsatanh DOUBLE PRECISION, INTENT(OUT) for vdatanh, vmdatanh COMPLEX, INTENT(OUT) for vcatanh, vmcatanh DOUBLE COMPLEX, INTENT(OUT) for vzatanh, vmzatanh	Array that specifies the output vector *y*.

Description

The v?Atanh function computes inverse hyperbolic tangent of vector elements.

Special Values for Real Function v?Atanh(x)

Argument	Result	VM Error Status	Exception
+1	+∞	VML_STATUS_SING	ZERODIVIDE
-1	-∞	VML_STATUS_SING	ZERODIVIDE

Argument	Result	VM Error Status	Exception

Notes:

- `Atanh(+-1+-i*0)=+-∞+-i*0`, and `ZERODIVIDE` exception is raised
- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- `Atanh(CONJ(z))=CONJ(Atanh(z))`
- `Atanh(-z)=-Atanh(z)`.

Special Functions

v?Erf

Computes the error function value of vector elements.

Syntax

```
call vserf( n, a, y )
call vserfi(n, a, inca, y, incy)
call vmserf( n, a, y, mode )
call vmserfi(n, a, inca, y, incy, mode)
call vderf( n, a, y )
call vderfi(n, a, inca, y, incy)
call vmderf( n, a, y, mode )
```

```
call vmderfi(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vderf, vmderf REAL, INTENT(IN) for vserf, vmserf DOUBLE PRECISION, INTENT(IN) for vderf, vmderf	Array, specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vderf, vmderf REAL, INTENT(OUT) for vserf, vmserf DOUBLE PRECISION, INTENT(OUT) for vderf, vmderf	Array, specifies the output vector *y*.

Description

The Erf function computes the error function values for elements of the input vector *a* and writes them to the output vector *y*.

The error function is defined as given by:

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

$$1.\quad \mathrm{erfc}(x) = 1 - \mathrm{erf}(x),$$

where `erfc` is the complementary error function.

$$2.\quad \Phi(x) = \frac{1}{2}\,\mathrm{erf}\,(x/\sqrt{2}),$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}}\int_0^x \exp\,(-t^2/2)dt$$

is the cumulative normal distribution function.

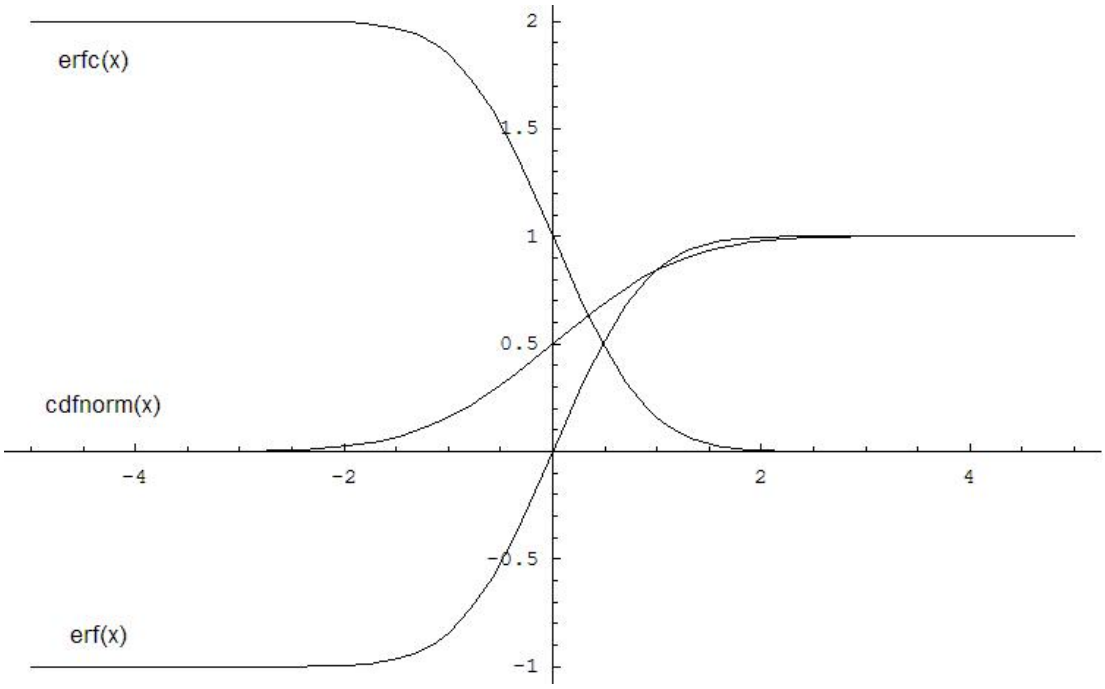
$$3.\quad \Phi^{-1}(x) = \sqrt{2}\,\mathrm{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\mathrm{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\mathrm{erf}(x)$ respectively.

The following figure illustrates the relationships among `Erf` family functions (`Erf`, `Erfc`, `CdfNorm`).

__border__top

Erf Family Functions Relationship



Useful relations for these functions:

$$\mathrm{erf}(x) + \mathrm{erfc}(x) = 1$$

$$\mathrm{cdfnorm}(x) = \frac{1}{2}\left(1 + \mathrm{erf}\left(\frac{x}{\sqrt{2}}\right)\right) = 1 - \frac{1}{2}\,\mathrm{erfc}\left(\frac{x}{\sqrt{2}}\right)$$

Special Values for Real Function v?Erf(x)

Argument	Result	Exception
+∞	+1	
-∞	-1	
QNAN	QNAN	
SNAN	QNAN	INVALID

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vderfc, vmderfc REAL, INTENT(IN) for vserfc, vmserfc DOUBLE PRECISION, INTENT(IN) for vderfc, vmderfc	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description

y	`DOUBLE PRECISION` for `vderfc`, `vmderfc`
	`REAL, INTENT(OUT)` for `vserfc`, `vmserfc`
	`DOUBLE PRECISION, INTENT(OUT)` for `vderfc, vmderfc`
		Array that specifies the output vector *y*.

Description

The `Erfc` function computes the complementary error function values for elements of the input vector *a* and writes them to the output vector *y*.

The complementary error function is defined as follows:

$$\mathrm{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_{x}^{\infty} e^{-t^2} dt .$$

Useful relations:

1. $\mathrm{erfc}(x) = 1 - \mathrm{erf}(x)$.

2. $\Phi(x) = \frac{1}{2} \mathrm{erf}\left(x/\sqrt{2}\right)$,

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{0}^{x} \exp\left(-t^2/2\right) dt$$

is the cumulative normal distribution function.

3. $\Phi^{-1}(x) = \sqrt{2}\, \mathrm{erf}^{-1}(2x - 1)$,

where $\Phi^{-1}(x)$ and $\mathrm{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\mathrm{erf}(x)$ respectively.

See also Figure "Erf Family Functions Relationship" in `Erf` function description for `Erfc` function relationship with the other functions of `Erf` family.

CdfNorm

v?CdfNorm

Computes the cumulative normal distribution function values of vector elements.

Syntax

```
call vscdfnorm( n, a, y )
call vscdfnormi(n, a, inca, y, incy)
call vmscdfnorm( n, a, y, mode )
call vmscdfnormi(n, a, inca, y, incy, mode)
call vdcdfnorm( n, a, y )
call vdcdfnormi(n, a, inca, y, incy)
call vmdcdfnorm( n, a, y, mode )
call vmdcdfnormi(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdcdfnorm, vmdcdfnorm REAL, INTENT(IN) for vscdfnorm, vmscdfnorm DOUBLE PRECISION, INTENT(IN) for vdcdfnorm, vmdcdfnorm	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description

y	`DOUBLE PRECISION` for `vdcdfnorm`, `vmdcdfnorm`
	`REAL, INTENT(OUT)` for `vscdfnorm`, `vmscdfnorm`
	`DOUBLE PRECISION, INTENT(OUT)` for `vdcdfnorm, vmdcdfnorm`
		Array that specifies the output vector *y*.

Description

The `CdfNorm` function computes the cumulative normal distribution function values for elements of the input vector *a* and writes them to the output vector *y*.

The cumulative normal distribution function is defined as given by:

$$\mathrm{CdfNorm}(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-\frac{t^2}{2}} dt .$$

Useful relations:

$$\mathrm{cdfnorm}(x) = \frac{1}{2}\left(1 + \mathrm{erf}\left(\frac{x}{\sqrt{2}}\right)\right) = 1 - \frac{1}{2}\,\mathrm{erfc}\left(\frac{x}{\sqrt{2}}\right)$$

where `Erf` and `Erfc` are the error and complementary error functions.

See also Figure "Erf Family Functions Relationship" in `Erf` function description for `CdfNorm` function relationship with the other functions of `Erf` family.

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vderfinv, vmderfinv REAL, INTENT(IN) for vserfinv, vmserfinv DOUBLE PRECISION, INTENT(IN) for vderfinv, vmderfinv	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vderfinv, vmderfinv REAL, INTENT(OUT) for vserfinv, vmserfinv DOUBLE PRECISION, INTENT(OUT) for vderfinv, vmderfinv	Array that specifies the output vector *y*.

Description

The ErfInv function computes the inverse error function values for elements of the input vector *a* and writes them to the output vector *y*

$y = \mathrm{erf}^{-1}(a)$,

where $\mathrm{erf}(x)$ is the error function defined as given by:

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

$$1.\quad \mathrm{erf}^{-1}(x) = \mathrm{erfc}^{-1}(1 - x),$$

where erfc is the complementary error function.

$$2.\quad \Phi(x) = \frac{1}{2}\,\mathrm{erf}\,(x/\sqrt{2}),$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp\,(-t^2/2)dt$$

is the cumulative normal distribution function.

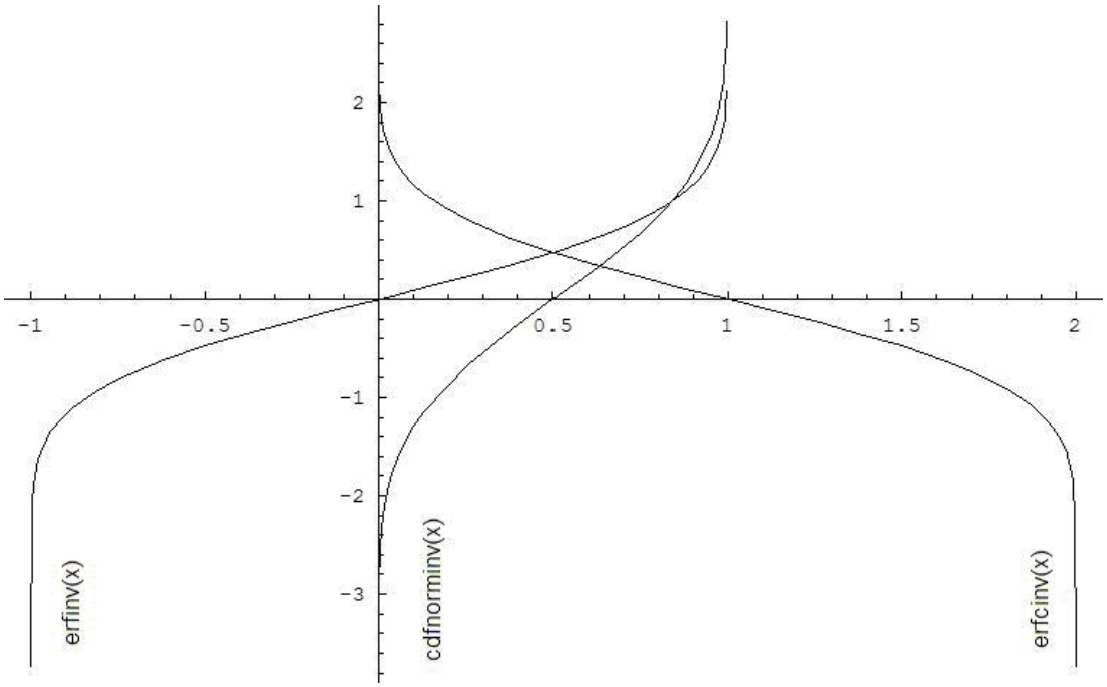
$$3.\quad \Phi^{-1}(x) = \sqrt{2}\,\mathrm{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\mathrm{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\mathrm{erf}(x)$ respectively.

Figure "ErfInv Family Functions Relationship" illustrates the relationships among `ErfInv` family functions (`ErfInv`, `ErfcInv`, `CdfNormInv`).

__border__top

ErfInv Family Functions Relationship



Useful relations for these functions:

$$\text{erfcinv}(x) = \text{erfinv}(1 - x)$$

$$\text{cdfnorminv}(x) = \sqrt{2}\text{erfinv}(2x - 1) = \sqrt{2}\text{erfcinv}(2 - 2x)$$

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vderfcinv, vmderfcinv REAL, INTENT(IN) for vserfcinv, vmserfcinv DOUBLE PRECISION, INTENT(IN) for vderfcinv, vmderfcinv	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vderfcinv, vmderfcinv REAL, INTENT(OUT) for vserfcinv, vmserfcinv DOUBLE PRECISION, INTENT(OUT) for vderfcinv, vmderfcinv	Array that specifies the output vector *y*.

Description

The ErfcInv function computes the inverse complimentary error function values for elements of the input vector *a* and writes them to the output vector *y*.

The inverse complementary error function is defined as given by:

$$\mathrm{erfcinv}(x) = \mathrm{erfinv}(1 - x)$$

$$\mathrm{erfinv}(x) = \mathrm{erf}^{-1}(x)$$

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

where `erf(x)` denotes the error function and `erfinv(x)` denotes the inverse error function.

See also Figure "ErfInv Family Functions Relationship" in `ErfInv` function description for `ErfcInv` function relationship with the other functions of `ErfInv` family.

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdcdfnorminv, vmdcdfnorminv REAL, INTENT(IN) for vscdfnorminv, vmscdfnorminv DOUBLE PRECISION, INTENT(IN) for vdcdfnorminv, vmdcdfnorminv	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdcdfnorminv, vmdcdfnorminv REAL, INTENT(OUT) for vscdfnorminv, vmscdfnorminv DOUBLE PRECISION, INTENT(OUT) for vdcdfnorminv, vmdcdfnorminv	Array that specifies the output vector *y*.

Description

The CdfNormInv function computes the inverse cumulative normal distribution function values for elements of the input vector *a* and writes them to the output vector *y*.

The inverse cumulative normal distribution function is defined as given by:

$$\mathrm{CdfNormInv}(x) = \mathrm{CdfNorm}^{-1}(x),$$

where `CdfNorm(x)` denotes the cumulative normal distribution function.

Useful relations:

$$\mathrm{cdfnorminv}(x) = \sqrt{2}\,\mathrm{erfinv}(2x - 1) = \sqrt{2}\,\mathrm{erfcinv}(2 - 2x)$$

where `erfinv(x)` denotes the inverse error function and `erfcinv(x)` denotes the inverse complementary error functions.

See also Figure "ErfInv Family Functions Relationship" in `ErfInv` function description for `CdfNormInv` function relationship with the other functions of `ErfInv` family.

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdlgamma, vmdlgamma REAL, INTENT(IN) for vslgamma, vmslgamma DOUBLE PRECISION, INTENT(IN) for vdlgamma, vmdlgamma	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdlgamma, vmdlgamma REAL, INTENT(OUT) for vslgamma, vmslgamma DOUBLE PRECISION, INTENT(OUT) for vdlgamma, vmdlgamma	Array that specifies the output vector *y*.

Description

The v?LGamma function computes the natural logarithm of the absolute value of gamma function for elements of the input vector *a* and writes them to the output vector *y*. Precision overflow thresholds for the v?LGamma function are beyond the scope of this document. If the result does not meet the target precision, the function raises the OVERFLOW exception and sets the VM Error Status to VML_STATUS_OVERFLOW.

```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	REAL (KIND=4), INTENT(IN) for vsexpint1, vmsexpint1	Array that specifies the input vector *a*.

Name	Type	Description
	`REAL (KIND=8), INTENT(IN)` for `vdexpint1, vmdexpint1`	
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	`INTEGER(KIND=8), INTENT(IN)`	Overrides global VM mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	`REAL (KIND=4), INTENT(OUT)` for `vsexpint1, vmsexpint1`	Array that specifies the output vector *y*.
	`REAL (KIND=8), INTENT(OUT)` for `vdexpint1, vmdexpint1`	

Description

The `v?ExpInt1` function computes the exponential integral E_1 of vector elements.

For positive real values *x*, this can be written as:

$$E_1(x) = \int_x^\infty \frac{e^{-t}}{t}\,\mathrm{d}t = \int_1^\infty \frac{e^{-xt}}{t}\,\mathrm{d}t.$$

For negative real values *x*, the result is defined as `NAN`.

v?NearbyInt

Computes a rounded integer value in the current rounding mode for each vector element.

Syntax

```
call vsnearbyint( n, a, y )
call vsnearbyinti(n, a, inca, y, incy)
call vmsnearbyint( n, a, y, mode )
call vmsnearbyinti(n, a, inca, y, incy, mode)
call vdnearbyint( n, a, y )
call vdnearbyinti(n, a, inca, y, incy)
call vmdnearbyint( n, a, y, mode )
call vmdnearbyinti(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdnearbyint, vmdnearbyint REAL, INTENT(IN) for vsnearbyint, vmsnearbyint DOUBLE PRECISION, INTENT(IN) for vdnearbyint, vmdnearbyint	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdnearbyint, vmdnearbyint REAL, INTENT(OUT) for vsnearbyint, vmsnearbyint DOUBLE PRECISION, INTENT(OUT) for vdnearbyint, vmdnearbyint	Array that specifies the output vector *y*.

Description

The v?NearbyInt function computes a rounded integer value in a current rounding mode for each vector element.

Special Values for Real Function v?NearbyInt(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Rint

Computes a rounded integer value in the current rounding mode.

Syntax

```
call vsrint( n, a, y )
call vsrinti(n, a, inca, y, incy)
call vmsrint( n, a, y, mode )
call vmsrinti(n, a, inca, y, incy, mode)
call vdrint( n, a, y )
call vdrinti(n, a, inca, y, incy)
call vmdrint( n, a, y, mode )
call vmdrinti(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdrint, vmdrint REAL, INTENT(IN) for vsrint, vmsrint DOUBLE PRECISION, INTENT(IN) for vdrint, vmdrint	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdrint, vmdrint REAL, INTENT(OUT) for vsrint, vmsrint DOUBLE PRECISION, INTENT(OUT) for vdrint, vmdrint	Array that specifies the output vector *y*.

Description

The v?Rint function computes a rounded floating-point integer value using the current rounding mode for each vector element.

The rounding mode affects the results computed for inputs that fall between consecutive integers. For example:

- f(0.5) = 0, for rounding modes set to round to nearest round toward zero or to minus infinity.
- f(0.5) = 1, for rounding modes set to plus infinity.
- f(-1.5) = -2, for rounding modes set to round to nearest or to minus infinity.
- f(-1.5) = -1, for rounding modes set to round toward zero or to plus infinity.

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Modf

Computes a truncated integer value and the remaining fraction part for each vector element.

Syntax

```
call vsmodf( n, a, y, z )
call vsmodfi(n, a, inca, y, incy, z, incz)
call vmsmodf( n, a, y, z, mode )
call vmsmodfi(n, a, inca, y, incy, z, incz, mode)
call vdmodf( n, a, y, z )
call vdmodfi(n, a, inca, y, incy, z, incz)
call vmdmodf( n, a, y, z, mode )
call vmdmodfi(n, a, inca, y, incy, z, incz, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdmodf, vmdmodf REAL, INTENT(IN) for vsmodf, vmsmodf DOUBLE PRECISION, INTENT(IN) for vdmodf, vmdmodf	Array, specifies the input vector *a*.
inca, *incy*, *incz*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *y*, and *z*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y, *z*	DOUBLE PRECISION for vdmodf, vmdmodf REAL, INTENT(OUT) for vsmodf, vmsmodf DOUBLE PRECISION, INTENT(OUT) for vdmodf, vmdmodf	Array, specifies the output vector *y* and *z*.

Description

The function computes a truncated integer value and the remaining fraction part for each vector element.

$$a_i \geq 0, \begin{cases} y_i = \lfloor a_i \rfloor \\ z_i = a_i - \lfloor a_i \rfloor \end{cases}$$

$$a_i < 0, \begin{cases} y_i = \lceil a_i \rceil \\ z_i = a_i - \lceil a_i \rceil \end{cases}$$

Special Values for Real Function v?Modf(x)

+0	+0	+0	
-0	-0	-0	
+∞	+∞	+0	
-∞	-∞	-0	
SNAN	QNAN	QNAN	INVALID
QNAN	QNAN	QNAN	

v?Frac

Computes a signed fractional part for each vector element.

Syntax

```
call vsfrac( n, a, y )
call vsfraci(n, a, inca, y, incy)
call vmsfrac( n, a, y, mode )
call vmsfraci(n, a, inca, y, incy, mode)
call vdfrac( n, a, y )
call vdfraci(n, a, inca, y, incy)
call vmdfrac( n, a, y, mode )
call vmdfraci(n, a, inca, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdfrac, vmdfrac REAL, INTENT(IN) for vsfrac, vmsfrac DOUBLE PRECISION, INTENT(IN) for vdfrac, vmdfrac	Array that specifies the input vector *a*.
inca, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a* and *y*.
mode	INTEGER(KIND=8), INTENT(IN)	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdfrac, vmdfrac REAL, INTENT(OUT) for vsfrac, vmsfrac DOUBLE PRECISION, INTENT(OUT) for vdfrac, vmdfrac	Array that specifies the output vector *y*.

Description

The function computes a signed fractional part for each vector element.

$$y_i = \begin{cases} a_i - \lfloor a_i \rfloor, a_i \geq 0 \\ a_i - \lceil a_i \rceil, a_i < 0 \end{cases}$$

VM Pack/Unpack Functions

This section describes VM functions that convert vectors with unit increment to and from vectors with positive increment indexing, vector indexing, and mask indexing (see Appendix "Vector Arguments in VM" for details on vector indexing methods).

The table below lists available VM Pack/Unpack functions, together with data types and indexing methods associated with them.

VM Pack/Unpack Functions

Function Short Name	Data Types	Indexing Methods	Description
v?pack	s, d, c, z	I,V,M	Gathers elements of arrays, indexed by different methods.
v?unpack	s, d, c, z	I,V,M	Scatters vector elements to arrays with different indexing.

See Also

Appendix "Vector Arguments in VM"

v?Pack

Copies elements of an array with specified indexing to a vector with unit increment.

Syntax

```
call vspacki( n, a, inca, y )
call vspackv( n, a, ia, y )
call vspackm( n, a, ma, y )
call vdpacki( n, a, inca, y )
call vdpackv( n, a, ia, y )
call vdpackm( n, a, ma, y )
call vcpacki( n, a, inca, y )
call vcpackv( n, a, ia, y )
call vcpackm( n, a, ma, y )
call vzpacki( n, a, inca, y )
call vzpackv( n, a, ia, y )
call vzpackm( n, a, ma, y )
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdpacki, vdpackv, vdpackm COMPLEX for vcpacki, vcpackv, vcpackm DOUBLE COMPLEX for vzpacki, vzpackv, vzpackm REAL, INTENT(IN) for vspacki, vspackv, vspackm DOUBLE PRECISION, INTENT(IN) for vdpacki, vdpackv, vdpackm COMPLEX, INTENT(IN) for vcpacki, vcpackv, vcpackm DOUBLE COMPLEX, INTENT(IN) for vzpacki, vzpackv, vzpackm	Array, DIMENSION at least (1 + (*n*-1)***inca*) for v?packi, Array, DIMENSION at least max(*n*,max(*ia*[j])), j=0, …, *n*-1 for v?packv, Array, DIMENSION at least *n* for v?packm. Specifies the input vector *a*.
inca	INTEGER, INTENT(IN) for vspacki, vdpacki, vcpacki, vzpacki	Specifies the increment for the elements of *a*.
ia	FORTRAN 77: INTEGER for vspackv, vdpackv, vcpackv, vzpackv INTEGER, INTENT(IN) for vspackv, vdpackv, vcpackv, vzpackv	Array, DIMENSION at least *n*. Specifies the index vector for the elements of *a*.
ma	FORTRAN 77: INTEGER for vspackm, vdpackm, vcpackm, vzpackm Fortran 90: INTEGER, INTENT(IN) for vspackm, vdpackm, vcpackm, vzpackm	Array, DIMENSION at least *n*, Specifies the mask vector for the elements of *a*.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdpacki, vdpackv, vdpackm COMPLEX for vcpacki, vcpackv, vcpackm	Array, DIMENSION at least *n*. Specifies the output vector *y*.

Name	Type	Description
	DOUBLE COMPLEX for vzpacki, vzpackv, vzpackm	
	REAL, INTENT(OUT) for vspacki, vspackv, vspackm	
	DOUBLE PRECISION, INTENT(OUT) for vdpacki, vdpackv, vdpackm	
	COMPLEX, INTENT(OUT) for vcpacki, vcpackv, vcpackm	
	DOUBLE COMPLEX, INTENT(OUT) for vzpacki, vzpackv, vzpackm	

v?Unpack

Copies elements of a vector with unit increment to an array with specified indexing.

Syntax

```
call vsunpacki( n, a, y, incy )
call vsunpackv( n, a, y, iy )
call vsunpackm( n, a, y, my )
call vdunpacki( n, a, y, incy )
call vdunpackv( n, a, y, iy )
call vdunpackm( n, a, y, my )
call vcunpacki( n, a, y, incy )
call vcunpackv( n, a, y, iy )
call vcunpackm( n, a, y, my )
call vzunpacki( n, a, y, incy )
call vzunpackv( n, a, y, iy )
call vzunpackm( n, a, y, my )
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	DOUBLE PRECISION for vdunpacki, vdunpackv, vdunpackm COMPLEX for vcunpacki, vcunpackv, vcunpackm	Array, DIMENSION at least *n*. Specifies the input vector *a*.

Name	Type	Description
	DOUBLE COMPLEX for vzunpacki, vzunpackv, vznpackm REAL, INTENT(IN) for vsunpacki, vsunpackv, vsunpackm DOUBLE PRECISION, INTENT(IN) for vdunpacki, vdunpackv, vdunpackm COMPLEX, INTENT(IN) for vcunpacki, vcunpackv, vcunpackm DOUBLE COMPLEX, INTENT(IN) for vzunpacki, vzunpackv, vzunpackm	
incy	INTEGER, INTENT(IN) for vsunpacki, vdunpacki, vcunpacki, vzunpacki	Specifies the increment for the elements of *y*.
iy	INTEGER, INTENT(IN) for vsunpackv, vdunpackv, vcunpackv, vzunpackv	Array, DIMENSION at least *n*. Specifies the index vector for the elements of *y*.
my	INTEGER, INTENT(IN) for vsunpackm, vdunpackm, vcunpackm, vzunpackm	Array, DIMENSION at least *n*, Specifies the mask vector for the elements of *y*.

Output Parameters

Name	Type	Description
y	DOUBLE PRECISION for vdunpacki, vdunpackv, vdunpackm COMPLEX, INTENT(IN) for vcunpacki, vcunpackv, vcunpackm DOUBLE COMPLEX, INTENT(IN) for vzunpacki, vzunpackv, vzunpackm REAL, INTENT(OUT) for vsunpacki, vsunpackv, vsunpackm DOUBLE PRECISION, INTENT(OUT) for vdunpacki, vdunpackv, vdunpackm COMPLEX, INTENT(OUT) for vcunpacki, vcunpackv, vcunpackm DOUBLE COMPLEX, INTENT(OUT) for vzunpacki, vzunpackv, vzunpackm	Array, DIMENSION for v?unpacki, at least (1 + (*n*-1)***incy*) for v?unpackv, at least max(*n*,max(*iy*[j])),j=0,..., *n*-1 for v?unpackm, at least *n* for v?UnpackI, at least (1 + (*n*-1)***incy*) for v?UnpackV, at least max(*n*,max(*ia*[j])),j=0,..., *n*-1, for v?UnpackM, at least *n*.

VM Service Functions

The VM Service functions enable you to set/get the accuracy mode and error code. These functions are available both in the Fortran and C interfaces. The table below lists available VM Service functions and their short description.

VM Service Functions

Function Short Name	Description
vmlsetmode	Sets the VM mode
vmlgetmode	Gets the VM mode
vmlseterrstatus	Sets the VM Error Status
vmlgeterrstatus	Gets the VM Error Status
vmlclearerrstatus	Clears the VM Error Status
vmlseterrorcallback	Sets the additional error handler callback function
vmlgeterrorcallback	Gets the additional error handler callback function
vmlclearerrorcallback	Deletes the additional error handler callback function

Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

Notice revision #20201201

vmlSetMode

Sets a new mode for VM functions according to the mode parameter and stores the previous VM mode to oldmode.

Syntax

```
oldmode = vmlsetmode( mode )
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
mode	INTEGER(KIND=8), INTENT(IN)	Specifies the VM mode to be set.

Output Parameters

Name	Type	Description
oldmode	INTEGER*8 INTEGER(KIND=8)	Specifies the former VM mode.

Description

The vmlSetMode function sets a new mode for VM functions according to the *mode* parameter and stores the previous VM mode to *oldmode*. The mode change has a global effect on all the VM functions within a thread.

NOTE
You can override the global mode setting and change the mode for a given VM function call by using a respective vm[s,d]<Func> variant of the function.

The *mode* parameter is designed to control accuracy, handling of denormalized numbers, and error handling. Table "Values of the *mode* Parameter" lists values of the *mode* parameter. You can obtain all other possible values of the *mode* parameter from the *mode* parameter values by a using bitwise `OR ( | )` operation to combine one value for accuracy, one value for handling of denormalized numbers, and one value for error control options. The default value of the *mode* parameter is `VML_HA | VML_FTZDAZ_CURRENT | VML_ERRMODE_DEFAULT`.

The `VML_FTZDAZ_ON` mode is specifically designed to improve the performance of computations that involve denormalized numbers at the cost of reasonable accuracy loss. This mode changes the numeric behavior of the functions: denormalized input values are treated as zeros (`DAZ` = denormals-are-zero) and denormalized results are flushed to zero (`FTZ` = flush-to-zero). Accuracy loss may occur if input and/or output values are close to denormal range.

Values of the *mode* Parameter

Value of *mode*	Description
Accuracy Control	
`VML_HA`	high accuracy versions of VM functions
`VML_LA`	low accuracy versions of VM functions
`VML_EP`	enhanced performance accuracy versions of VM functions
Denormalized Numbers Handling Control	
`VML_FTZDAZ_ON`	Faster processing of denormalized inputs is enabled.
`VML_FTZDAZ_OFF`	Faster processing of denormalized inputs is disabled.
`VML_FTZDAZ_CURRENT`	Keep the current CPU settings for denormalized inputs.
Error Mode Control	
`VML_ERRMODE_IGNORE`	On computation error, VM Error status is updated, but otherwise no action is set. Cannot be combined with other `VML_ERRMODE` settings.
`VML_ERRMODE_NOERR`	On computation error, VM Error status is not updated and no action is set. Cannot be combined with other `VML_ERRMODE` settings.
`VML_ERRMODE_STDERR`	On error, the error text information is written to *stderr*.
`VML_ERRMODE_EXCEPT`	On error, an exception is raised.
`VML_ERRMODE_CALLBACK`	On error, an additional error handler function is called.
`VML_ERRMODE_DEFAULT`	On error, an exception is raised and an additional error handler function is called.

Examples

The following example shows how to set low accuracy, fast processing for denormalized numbers and `stderr` error mode:

```
oldmode = vmlsetmode( VML_LA )
call vmlsetmode( IOR(VML_LA, VML_FTZDAZ_ON, VML_ERRMODE_STDERR) )
```

vmlgetmode

Gets the VM mode.

Syntax

```
mod = vmlgetmode()
```

Include Files

- mkl_vml.f90

Output Parameters

Name	Type	Description
mod	INTEGER	Specifies the packed *mode* parameter.

Description

The function `vmlgetmode` returns the VM *mode* parameter that controls accuracy, handling of denormalized numbers, and error handling options. The *mod* variable value is a combination of the values listed in the table "Values of the *mode* Parameter". You can obtain these values using the respective mask from the table "Values of Mask for the *mode* Parameter".

Values of Mask for the *mode* Parameter

Value of mask	Description
VML_ACCURACY_MASK	Specifies mask for accuracy *mode* selection.
VML_FTZDAZ_MASK	Specifies mask for FTZDAZ *mode* selection.
VML_ERRMODE_MASK	Specifies mask for error *mode* selection.

See example below:

Examples

```
mod = vmlgetmode()
accm = IAND(mod, VML_ACCURACY_MASK)
denm = IAND(mod, VML_FTZDAZ_MASK)
errm = IAND(mod, VML_ERRMODE_MASK)
```

vmlSetErrStatus

Sets the new VM Error Status according to err and stores the previous VM Error Status to olderrSets the global VM Status according to new values and returns the previous VM Status.

Syntax

```
olderr = vmlseterrstatus( status )
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
status	INTEGER, INTENT(IN)	Specifies the VM error status to be set.

Output Parameters

Name	Type	Description
olderr	INTEGER	Specifies the former VM error status.

Description

Table "Values of the VM Status" lists possible values of the *err* parameter.

Values of the VM Status

Status	Description
Successful Execution	
VML_STATUS_OK	The execution was completed successfully.
Warnings	
VML_STATUS_ACCURACYWARNING	The execution was completed successfully in a different accuracy mode.
Errors	
VML_STATUS_BADSIZE	The function does not support the preset accuracy mode. The Low Accuracy mode is used instead.
VML_STATUS_BADMEM	NULL pointer is passed.
VML_STATUS_ERRDOM	At least one of array values is out of a range of definition.
VML_STATUS_SING	At least one of the input array values causes a divide-by-zero exception or produces an invalid (QNaN) result.
VML_STATUS_OVERFLOW	An overflow has happened during the calculation process.
VML_STATUS_UNDERFLOW	An underflow has happened during the calculation process.

Examples

```
olderr = vmlSetErrStatus( VML_STATUS_OK );
olderr = vmlSetErrStatus( VML_STATUS_ERRDOM );
olderr = vmlSetErrStatus( VML_STATUS_UNDERFLOW );
```

vmlgeterrstatus

Gets the VM Error Status.

Syntax

```
err = vmlgeterrstatus( )
```

Include Files

- mkl_vml.f90

Output Parameters

Name	Type	Description
err	INTEGER	Specifies the VM error status.

vmlclearerrstatus

Sets the VM Error Status to VML_STATUS_OK *and stores the previous VM Error Status to olderr.*

Syntax

olderr = vmlclearerrstatus( )

Include Files

- mkl_vml.f90

Output Parameters

Name	Type	Description
olderr	INTEGER	Specifies the former VM error status.

vmlSetErrorCallBack

Sets the additional error handler callback function and gets the old callback function.

Syntax

oldcallback = vmlseterrorcallback(*callback*)

Include Files

- mkl_vml.f90

Input Parameters

Name		Description

callback	Address of the callback function.	The callback function has the following format:
		`INTEGER FUNCTION ERRFUNC(par)`
		`TYPE (ERROR_STRUCTURE) par`
		`! ...`
		`! user error processing`
		`! ...`
		`ERRFUNC = 0`
		`! if ERRFUNC= 0 - standard VM error handler`
		`! is called after the callback`
		`! if ERRFUNC != 0 - standard VM error handler`
		`! is not called`
		`END`
		The passed error structure is defined as follows:
		`TYPE ERROR_STRUCTURE SEQUENCE`
		`INTEGER*4 ICODE`
		`INTEGER*4 IINDEX`
		`REAL*8 DBA1`
		`REAL*8 DBA2`
		`REAL*8 DBR1`
		`REAL*8 DBR2`
		`CHARACTER(64) CFUNCNAME`
		`INTEGER*4 IFUNCNAMELEN`
		`REAL*8 DBA1IM`
		`REAL*8 DBA2IM`
		`REAL*8 DBR1IM`
		`REAL*8 DBR2IM`
		`END TYPE ERROR_STRUCTURE`

Output Parameters

Name	Type	Description
oldcallback	INTEGER	Address of the former callback function.

NOTE
This function does not have a FORTRAN 77 interface due to the use of internal structures.

Description

The callback function is called on each VM mathematical function error if `VML_ERRMODE_CALLBACK` error mode is set (see "Values of the *mode* Parameter").

Use the `vmlSetErrorCallBack()` function if you need to define your own callback function instead of default empty callback function.

The input structure for a callback function contains the following information about the error encountered:

- the input value that caused an error
- location (array index) of this value
- the computed result value
- error code
- name of the function in which the error occurred.

You can insert your own error processing into the callback function. This may include correcting the passed result values in order to pass them back and resume computation. The standard error handler is called after the callback function only if it returns *0*.

vmlGetErrorCallBack

Gets the additional error handler callback function.

Syntax

callback = vmlgeterrorcallback( )

Include Files

- mkl_vml.f90

Output Parameters

Name	Description
callback	Address of the callback function

vmlClearErrorCallBack

Deletes the additional error handler callback function and retrieves the former callback function.

Syntax

oldcallback = vmlclearerrorcallback( )

Include Files

- mkl_vml.f90

Output Parameters

Name	Type	Description
oldcallback	INTEGER	Address of the former callback function

Miscellaneous VM Functions

v?CopySign

Returns vector of elements of one argument with signs changed to match other argument elements.

Syntax

```
call vscopysign (n, a, y)
call vscopysigni(n, a, inca, b, incb, y, incy)
call vmscopysign (n, a, y, mode)
call vmscopysigni(n, a, inca, b, incb, y, incy, mode)
call vdcopysign (n, a, y)
call vdcopysigni(n, a, inca, b, incb, y, incy)
call vmdcopysign (n, a, y, mode)
call vmdcopysigni(n, a, inca, b, incb, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER	Specifies the number of elements to be calculated.
a	REAL for vscopysign REAL for vmscopysign DOUBLE PRECISION for vdcopysign DOUBLE PRECISION for vmdcopysign	Pointer to the array containing the input vector *a*.
inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
mode	INTEGER (KIND=8)	Overrides the global VM *mode* setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	REAL for vscopysign REAL for vmscopysign DOUBLE PRECISION for vdcopysign DOUBLE PRECISION for vmdcopysign	Pointer to an array containing the output vector *y*.

Description

The v?CopySign function returns the first vector argument elements with the sign changed to match the sign of the second vector argument's corresponding elements.

v?NextAfter

Returns vector of elements containing the next representable floating-point values following the values from the elements of one vector in the direction of the corresponding elements of another vector.

Syntax

```
call vsnextafter (n, a, b, y)
call vsnextafteri(n, a, inca, b, incb, y, incy)
call vmsnextafter (n, a, b, y, mode)
call vmsnextafteri(n, a, inca, b, incb, y, incy, mode)
call vdnextafter (n, a, b, y)
call vdnextafteri(n, a, inca, b, incb, y, incy)
call vmdnextafter (n, a, b, y, mode)
call vmdnextafteri(n, a, inca, b, incb, y, incy, mode)
```

Include Files

- mkl_vml.f90

Input Parameters

Name	Type	Description
n	INTEGER	Specifies the number of elements to be calculated.
a, *b*	REAL for vsnextafter REAL for vmsnextafter DOUBLE PRECISION for vdnextafter DOUBLE PRECISION for vmdnextafter	Pointers to the arrays containing the input vectors *a* and *b*.
inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
mode	INTEGER (KIND=8)	Overrides the global VM *mode* setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	REAL for vsnextafter	Pointer to an array containing the output vector *y*.

Name	Type	Description
	`REAL` for `vmsnextafter`	
	`DOUBLE PRECISION` for `vdnextafter`	
	`DOUBLE PRECISION` for `vmdnextafterjjssd`	

Description

The `v?NextAfter` function returns a vector containing the next representable floating-point values following the first vector argument elements in the direction of the second vector argument's corresponding elements.

Special cases:

Overflow	The function raises overflow and inexact floating-point exceptions and sets `VML_STATUS_OVERFLOW` if an input vector argument element is finite and the corresponding result vector element value is infinite.
Underflow	The function raises underflow and inexact floating-point exceptions and sets `VML_STATUS_UNDERFLOW` if a result vector element value is subnormal or zero, and different from the corresponding input vector argument element.

Even though underflow or overflow can occur, the returned value is independent of the current rounding direction mode.

v?Fdim

Returns vector containing the differences of the corresponding elements of the vector arguments if the first is larger and +0 otherwise.

Syntax

```
call vsfdim (n, a, b, y)
call vsfdimi(n, a, inca, b, incb, y, incy)
call vmsfdim (n, a, b, y, mode)

Input Parameters

Name	Type	Description
n	`INTEGER`	Specifies the number of elements to be calculated.

Name	Type	Description

a, *b*	`REAL` for `vsfdim`
	`REAL` for `vmsfdim`
	`DOUBLE PRECISION` for `vdfdim`
	`DOUBLE PRECISION` for `vmdfdim`
		Pointers to the arrays containing the input vectors *a* and *b*.

inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
mode	`INTEGER (KIND=8)`	Overrides the global VM *mode* setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description

y	`REAL` for `vsfdim`
	`REAL` for `vmsfdim`
	`DOUBLE PRECISION` for `vdfdim`
	`DOUBLE PRECISION` for `vmdfdimjjssd`
		Pointer to an array containing the output vector *y*.

Description

The `v?Fdim` function returns a vector containing the differences of the corresponding elements of the first and second vector arguments if the first element is larger, and +0 otherwise.

Special values for Real Function v?Fdim(x, y)

Argument 1	Argument 2	Result	VM Error Status	Exception
any	QNAN	QNAN		
any	SNAN	QNAN		INVALID
QNAN	any	QNAN		
SNAN	any	QNAN		INVALID

v?Fmax

Returns the larger of each pair of elements of the two vector arguments.

Syntax

```
call vsfmax (n, a, b, y)
call vsfmaxi(n, a, inca, b, incb, y, incy)
call vmsfmax (n, a, b, y, mode)
call vmsfmaxi(n, a, inca, b, incb, y, incy, mode)
call vdfmax (n, a, b, y)
call vdfmaxi(n, a, inca, b, incb, y, incy)
call vmdfmax (n, a, b, y, mode)
call vmdfmaxi(n, a, inca, b, incb, y, incy, mode)
```

Input Parameters

Name	Type	Description
n	INTEGER	Specifies the number of elements to be calculated.
a, *b*	REAL for vsfmax REAL for vmsfmax DOUBLE PRECISION for vdfmax DOUBLE PRECISION for vmdfmax	Pointers to the arrays containing the input vectors *a* and *b*.
inca, *incb*, *incy*	INTEGER, INTENT(IN)	Specifies increments for the elements of *a*, *b*, and *y*.
mode	INTEGER (KIND=8)	Overrides the global VM *mode* setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	REAL for vsfmax REAL for vmsfmax DOUBLE PRECISION for vdfmax DOUBLE PRECISION for vmdfmaxjjssd	Pointer to an array containing the output vector *y*.

Description

The v?Fmax function returns a vector with element values equal to the larger value from each pair of corresponding elements of the two vectors *a* and *b*: if $a_i < b_i$ v?Fmax returns b_i, otherwise v?Fmax returns a_i.

Special values for Real Function v?Fmax(x, y)

Argument 1	Argument 2	Result	VM Error Status	Exception
a_i not NAN	NAN	a_i		
NAN	b_i not NAN	b_i		
NAN	NAN	NAN		

See Also

Fmin Returns the smaller of each pair of elements of the two vector arguments.

MaxMag Returns the element with the larger magnitude between each pair of elements of the two vector arguments.

v?Fmin

Returns the smaller of each pair of elements of the two vector arguments.

Syntax

```
call vsfmin (n, a, b, y)
call vsfmini(n, a, inca, b, incb, y, incy)
call vmsfmin (n, a, b, y, mode)
call vmsfmini(n, a, inca, b, incb, y, incy, mode)
call vdfmin (n, a, b, y)
call vdfmini(n, a, inca, b, incb, y, incy)

Fmin Returns the smaller of each pair of elements of the two vector arguments.

Statistical Functions

Statistical functions in Intel® oneAPI Math Kernel Library (oneMKL) are known as the Vector Statistics (VS). They are designed for the purpose of

- generating vectors of pseudorandom, quasi-random, and non-deterministic random numbers
- performing mathematical operations of convolution and correlation
- computing basic statistical estimates for single and double precision multi-dimensional datasets

The corresponding functionality is described in the respective Random Number Generators, Convolution and Correlation, and Summary Statistics topics.

See VS performance data in the online VS Performance Data document available at https://www.intel.com/content/www/us/en/developer/tools/oneapi/onemkl-documentation.html.

The basic notion in VS is a task. The task object is a data structure or descriptor that holds the parameters related to a specific statistical operation: random number generation, convolution and correlation, or summary statistics estimation. Such parameters can be an identifier of a random number generator, its internal state and parameters, data arrays, their shape and dimensions, an identifier of the operation and so forth. You can modify the VS task parameters using the VS service functions.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Random Number Generators

Intel® oneAPI Math Kernel Library (oneMKL) VS provides a set of routines implementing commonly used pseudorandom, quasi-random, or non-deterministic random number generators with continuous and discrete distribution. To improve performance, all these routines were developed using the calls to the highly optimized*Basic Random Number Generators* (BRNGs) and vector mathematical functions (VM, see "Vector Mathematical Functions").

VS provides interfaces both for Fortran and C languages. For users of the Fortran 90 or Fortran 95 language the `mkl_vsl.f90` header file is provided. The `mkl_vsl.fi`header file available in the previous versions of Intel® oneAPI Math Kernel Library (oneMKL) is retained for backward compatibility.All header files are found in the following directory:

```
${MKL}/include
```

The `mkl_vsl.f90` header is intended for use with the Fortran `include` clause and is compatible with both standard forms of F90/F95 sources - the free and 72-columns fixed forms. If you need to use the VS interface with 80- or 132-columns fixed form sources, you may add a new file to your project. That file is formatted as a 72-columns fixed-form source and consists of a single `include` clause as follows:

```
include 'mkl_vsl.f90'
```

This `include` clause causes the compiler to generate the module files `mkl_vsl.mod` and `mkl_vsl_type.mod`, which are used to process the Fortran use clauses referencing to the VS interface:

```
use mkl_vsl_type
```

```
use mkl_vsl
```

Because of this specific feature, you do not need to include the `mkl_vsl.f90` header into each source of your project. You only need to include the header into some of the sources. In any case, make sure that the sources that depend on the VS interface are compiled after those that include the header so that the module files `mkl_vsl.mod` and `mkl_vsl_type.mod` are generated prior to using them.

NOTE
For the Fortran interface, VS provides both a subroutine-style interface and a function-style interface. The default interface in this case is a function-style interface. The function-style interface, unlike the subroutine-style interface, allows the user to get error status of each routine. The subroutine-style interface is provided for backward compatibility only. To use the subroutine-style interface, manually include `mkl_vsl_subroutine.fi` file instead of `mkl_vsl.f90` by changing the line `include 'mkl_vsl.f90'` in `include\mkl.fi` with the line `include 'mkl_vsl_subroutine.fi'`.

All VS routines can be classified into three major categories:

- Transformation routines for different types of statistical distributions, for example, uniform, normal (Gaussian), binomial, etc. These routines indirectly call basic random number generators, which are pseudorandom, quasi-random, or non-deterministic random number generators. Detailed description of the generators can be found in Distribution Generators.
- Service routines to handle random number streams: create, initialize, delete, copy, save to a binary file, load from a binary file, get the index of a basic generator. The description of these routines can be found in Service Routines.
- Registration routines for basic pseudorandom generators and routines that obtain properties of the registered generators (see Advanced Service Routines).

The last two categories are referred to as service routines.

Random Number Generators Conventions

This document makes no specific differentiation between random, pseudorandom, and quasi-random numbers, nor between random, pseudorandom, and quasi-random number generators unless the context requires otherwise. For details, refer to the '*Random Numbers*' section in VS Notesdocument provided at the Intel® oneAPI Math Kernel Library (oneMKL) web page.

All generators of nonuniform distributions, both discrete and continuous, are built on the basis of the uniform distribution generators, called Basic Random Number Generators (BRNGs). The pseudorandom numbers with nonuniform distribution are obtained through an appropriate transformation of the uniformly distributed pseudorandom numbers. Such transformations are referred to as *generation methods*. For a given distribution, several generation methods can be used. See VS Notes for the description of methods available for each generator.

An RNG task determines environment in which random number generation is performed, in particular parameters of the BRNG and its internal state. Output of VS generators is a stream of random numbers that are used in Monte Carlo simulations. A *random stream descriptor* and a *random stream* are used as synonyms of an *RNG task* in the document unless the context requires otherwise.

The *random stream descriptor* specifies which BRNG should be used in a given transformation method. See the *Random Streams and RNGs in Parallel Computation* section of VS Notes.

The term *computational node* means a logical or physical unit that can process data in parallel.

Random Number Generators Mathematical Notation

The following notation is used throughout the text:

N	The set of natural numbers $N = \{1, 2, 3 \ldots\}$.
Z	The set of integers $Z = \{\ldots -3, -2, -1, 0, 1, 2, 3 \ldots\}$.
R	The set of real numbers.

$\lfloor a \rfloor$

The floor of *a* (the largest integer less than or equal to *a*).

⊕ or **xor**

Bitwise exclusive OR.

C_α^κ or $\binom{\alpha}{\kappa}$

Binomial coefficient or combination ($\alpha \in R$, $\alpha \geq 0$; $k \in N \cup \{0\}$).

$$C_\alpha^0 = 1$$

For $\alpha \geq k$ binomial coefficient is defined as

$$C_\alpha^\kappa = \frac{\alpha(\alpha - 1) \ldots (\alpha - \kappa + 1)}{\kappa!}$$

If $\alpha < k$, then

$$C_\alpha^\kappa = 0$$

$\Phi(x)$

Cumulative Gaussian distribution function

$$\Phi(x) = \int_{-\infty}^{x} \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y^2}{2}\right) dy$$

defined over $-\infty < x < +\infty$.

$\Phi(-\infty) = 0$, $\Phi(+\infty) = 1$.

$\Gamma(\alpha)$

The complete gamma function

$$\Gamma(\alpha) = \int_0^\infty t^{\alpha-1} e^{-t} dt$$

where $\alpha > 0$.

B(*p*, *q*)

The complete beta function

$$B(p,q) = \int_0^1 t^{p-1}(1-t)^{q-1}dt$$

where $p>0$ and $q>0$.

LCG(*a*,*c*, *m*)	Linear Congruential Generator $x_{n+1} = (ax_n + c) \bmod m$, where *a* is called the *multiplier*, *c* is called the *increment*, and *m* is called the *modulus* of the generator.
MCG(*a*,*m*)	Multiplicative Congruential Generator $x_{n+1} = (ax_n) \bmod m$ is a special case of Linear Congruential Generator, where the increment *c* is taken to be 0.
GFSR(*p*, *q*)	Generalized Feedback Shift Register Generator $x_n = x_{n-p} \oplus x_{n-q}$.

Random Number Generators Naming Conventions

The names of the routines in VS random number generators are lowercase (`virnguniform`). The names are not case-sensitive.

The names of generator routines have the following structure:

`v<type of result>rng<distribution>`

where

- `v` is the prefix of a VS vector function.
- <*type of result*> is either `s`, `d`, or `i` and specifies one of the following types:

`s`	`REAL`
`d`	`DOUBLE PRECISION`
`i`	`INTEGER`

  Prefixes `s` and `d` apply to continuous distributions only, prefix `i` applies only to discrete case.

- `rng` indicates that the routine is a random generator.
- <*distribution*> specifies the type of statistical distribution.

Names of service routines follow the template below:

```
vsl<name>
```

where

- `vsl` is the prefix of a VS service function.
- <*name*> contains a short function name.

For a more detailed description of service routines, refer to Service Routines and Advanced Service Routines.

The prototype of each generator routine corresponding to a given probability distribution fits the following structure:

```
status = <function name>( method, stream, n, r, [<distribution parameters>] )
```

where

- *method* defines the method of generation. A detailed description of this parameter can be found in table "Values of <*method*> in *method* parameter". See below, where the structure of the *method* parameter name is explained.
- *stream* defines the descriptor of the random stream and must have a non-zero value. Random streams, descriptors, and their usage are discussed further in Random Streams and Service Routines.
- *n* defines the number of random values to be generated. If *n* is less than or equal to zero, no values are generated. Furthermore, if *n* is negative, an error condition is set.
- *r* defines the destination array for the generated numbers. The dimension of the array must be large enough to store at least *n* random numbers.
- *status* defines the error status of a VS routine. See Error Reporting for a detailed description of error status values.

Additional parameters included into <*distribution parameters*> field are individual for each generator routine and are described in detail in Distribution Generators.

To invoke a distribution generator, use a call to the respective VS routine. For example, to obtain a vector *r*, composed of *n* independent and identically distributed random numbers with normal (Gaussian) distribution, that have the mean value *a* and standard deviation *sigma*, write the following:

```
status = vsrnggaussian( method, stream, n, r, a, sigma )
```

The name of a *method* parameter has the following structure:

```
VSL_RNG_METHOD_method<distribution>_<method>
```

```
VSL_RNG_METHOD_<distribution>_<method>_ACCURATE
```

where

- <*distribution*> is the probability distribution.
- <*method*> is the method name.

Type of the name structure for the *method* parameter corresponds to fast and accurate modes of random number generation (see "Distribution Generators" and VS Notes for details).

Method names VSL_RNG_METHOD_<*distribution*>_<*method*>

and

VSL_RNG_METHOD_<*distribution*>_<*method*>_ACCURATE

should be used with

v<*precision*>Rng<*distribution*>

function only, where

- <*precision*> is

s	for single precision continuous distribution
d	for double precision continuous distribution
i	for discrete distribution

- <*distribution*> is the probability distribution.

is the probability distribution.Table "Values of <*method*> in *method* parameter" provides specific predefined values of the *method* name. The third column contains names of the functions that use the given method.

Values of <*method*> in *method* parameter

Method	Short Description	Functions
STD	Standard method. Currently there is only one method for these functions.	Uniform (continuous), Uniform (discrete),

Method	Short Description	Functions
		UniformBits, UniformBits32, UniformBits64
BOXMULLER	BOXMULLER generates normally distributed random number x thru the pair of uniformly distributed numbers u_1 and u_2 according to the formula: $x = \sqrt{-2 \ln u_1} \sin 2\pi u_2$	Gaussian, GaussianMV
BOXMULLER2	BOXMULLER2 generates normally distributed random numbers x_1 and x_2 thru the pair of uniformly distributed numbers u_1 and u_2 according to the formulas: $x_1 = \sqrt{-2 \ln u_1} \sin 2\pi u_2$ $x_2 = \sqrt{-2 \ln u_1} \cos 2\pi u_2$	Gaussian, GaussianMV, Lognormal
ICDF	Inverse cumulative distribution function method.	Exponential, Laplace, Weibull, Cauchy, Rayleigh, Gumbel, Bernoulli, Geometric, Gaussian, GaussianMV, Lognormal
GNORM	For $\alpha > 1$, a gamma distributed random number is generated as a cube of properly scaled normal random number; for $0.6 \le \alpha < 1$, a gamma distributed random number is generated using rejection from Weibull distribution; for $\alpha < 0.6$, a gamma distributed random number is obtained using transformation of exponential power distribution; for $\alpha = 1$, gamma distribution is reduced to exponential distribution.	Gamma
CJA	For $min(p, q) > 1$, Cheng method is used; for $min(p, q) < 1$, Johnk method is used, if $q + K \cdot p^2 + C \le 0$ (K = 0.852..., C=-0.956...) otherwise, Atkinson switching algorithm is used; for $max(p, q) < 1$, method of Johnk is used; for $min(p, q) < 1$, $max(p, q) > 1$, Atkinson switching algorithm is used (CJA stands for the first letters of Cheng, Johnk, Atkinson); for $p = 1$ or $q = 1$, inverse cumulative distribution function method is used;for $p = 1$ and $q = 1$, beta distribution is reduced to uniform distribution.	Beta
BTPE	Acceptance/rejection method for $ntrial \cdot \min(p, 1 - p) \ge 30$ with decomposition into 4 regions:	Binomial

Method	Short Description	Functions
	– 2 parallelograms – triangle – left exponential tail – right exponential tail	
H2PE	Acceptance/rejection method for large mode of distribution with decomposition into 3 regions: – rectangular – left exponential tail – right exponential tail	Hypergeometric
PTPE	Acceptance/rejection method for $\lambda \geq 27$ with decomposition into 4 regions: – 2 parallelograms – triangle – left exponential tail – right exponential tail; otherwise, table lookup method is used.	Poisson
POISNORM	for $\lambda \geq 1$, method based on Poisson inverse CDF approximation by Gaussian inverse CDF; for $\lambda < 1$, table lookup method is used.	Poisson, PoissonV
NBAR	Acceptance/rejection method for , $\frac{(a-1)\cdot(1-p)}{p} \geq 100$ with decomposition into 5 regions: – rectangular – 2 trapezoid – left exponential tail – right exponential tail	NegBinomial
CHI2GAMMA	Random number generator of chi-square distribution with v degrees of freedom. To generate any successive random number x of the chi-square distribution: • If v is 1 or 3, a chi-square distributed random number is generated as a sum of squares of v independent normal random numbers with mean value a = 0 and standard deviation σ =1. • If v is even and $2 \leq v \leq 16$, a chi-square distributed random number is generated using the formula: $x = -2ln\left(\prod_{i=1}^{v/2} u_i\right)$ where u_i are successive random numbers uniformly distributed over the interval (0, 1) • If $v \geq 17$ or v is odd and $5 \leq v \leq 15$, a chi-square distribution is reduced to a Gamma distribution with these parameters:	ChiSquare

Method	Short Description	Functions
	• Shape $a = v / 2$ • Offset a = 0 • Scale factor $\beta = 2$ The random numbers of the Gamma distribution are generated using the VSL_RNG_METHOD_GAMMA_GNORM method.	

NOTE
In this document, routines are often referred to by their base name (`Gaussian`) when this does not lead to ambiguity. In the routine reference, the full name (`vsrnggaussian`, `vsRngGaussian`) is always used in prototypes and code examples.

Basic Generators

VS provides pseudorandom, quasi-random, and non-deterministic random number generators. This includes the following BRNGs, which differ in speed and other properties:

- the 31-bit multiplicative congruential pseudorandom number generator $MCG(1132489760, 2^{31} - 1)$ [L'Ecuyer99]
- the 32-bit generalized feedback shift register pseudorandom number generator $GFSR(250,103)$ [Kirkpatrick81]
- the combined multiple recursive pseudorandom number generator *MRG32k3a* [L'Ecuyer99a]
- the 59-bit multiplicative congruential pseudorandom number generator $MCG(13^{13}, 2^{59})$ from NAG Numerical Libraries [NAG]
- Wichmann-Hill pseudorandom number generator (a set of 273 basic generators) from NAG Numerical Libraries [NAG]
- Mersenne Twister pseudorandom number generator *MT19937* [Matsumoto98] with period length 2^{19937}-1 of the produced sequence
- Set of 6024 Mersenne Twister pseudorandom number generators *MT2203* [Matsumoto98], [Matsumoto00]. Each of them generates a sequence of period length equal to 2^{2203}-1. Parameters of the generators provide mutual independence of the corresponding sequences.
- SIMD-oriented Fast Mersenne Twister pseudorandom number generator *SFMT19937* [Saito08] with a period length equal to 2^{19937}-1 of the produced sequence.
- Sobol quasi-random number generator [Sobol76], [Bratley88], which works in arbitrary dimension. For dimensions greater than 40 the user should supply initialization parameters (initial direction numbers and primitive polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in VS Notes.
- Niederreiter quasi-random number generator [Bratley92], which works in arbitrary dimension. For dimensions greater than 318 the user should supply initialization parameters (irreducible polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in VS Notes.
- Non-deterministic random number generator (RDRAND-based generators only) [AVX], [IntelSWMan].

NOTE
You can use a non-deterministic random number generator only if the underlying hardware supports it. For instructions on how to detect if an Intel CPU supports a non-deterministic random number generator see, for example, *Chapter 8: Post-32nm Processor Instructions* in [AVX] or *Chapter 4: RdRand Instruction Usage* in [BMT].

NOTE
The time required by some non-deterministic sources to generate a random number is not constant, so you might have to make multiple requests before the next random number is available. VS limits the number of retries for requests to the non-deterministic source to 10. You can redefine the maximum number of retries during the initialization of the non-deterministic random number generator with the vslNewStreamEx function.

For more details on the non-deterministic source implementation for Intel CPUs please refer to Section 7.3.17, Volume 1, *Random Number Generator Instruction* in [IntelSWMan] and Section 4.2.2, *RdRand Retry Loop* in [BMT].

- Philox4x32-10 counter-based pseudorandom number generator with a period of 2^{128} *PHILOX4X32X10*[Salmon11].
- ARS-5 counter-based pseudorandom number generator with a period of 2^{128}, which uses instructions from the AES-NI set *ARS5*[Salmon11].

See some testing results for the generators in VS Notes and comparative performance data at https://www.intel.com/content/www/us/en/developer/tools/oneapi/onemkl-documentation.html.

VS provides means of registration of such user-designed generators through the steps described in Advanced Service Routines.

For some basic generators, VS provides two methods of creating independent random streams in multiprocessor computations, which are the leapfrog method and the block-splitting method. These sequence splitting methods are also useful in sequential Monte Carlo.

In addition, MT2203 pseudorandom number generator is a set of 6024 generators designed to create up to 6024 independent random sequences, which might be used in parallel Monte Carlo simulations. Another generator that has the same feature is Wichmann-Hill. It allows creating up to 273 independent random streams. The properties of the generators designed for parallel computations are discussed in detail in [Coddington94].

You may want to design and use your own basic generators. VS provides means of registration of such user-designed generators through the steps described in Advanced Service Routines.

There is also an option to utilize externally generated random numbers in VS distribution generator routines. For this purpose VS provides three additional basic random number generators:

- for external random data packed in 32-bit integer array
- for external random data stored in double precision floating-point array; data is supposed to be uniformly distributed over (a,b) interval
- for external random data stored in single precision floating-point array; data is supposed to be uniformly distributed over (a,b) interval.

Such basic generators are called the abstract basic random number generators.

See VS Notes for a more detailed description of the generator properties.

BRNG Parameter Definition

Predefined values for the *brng* input parameter are as follows:

Values of *brng* parameter

Value	Short Description
VSL_BRNG_MCG31	A 31-bit multiplicative congruential generator.

Value	Short Description
VSL_BRNG_R250	A generalized feedback shift register generator.
VSL_BRNG_MRG32K3A	A combined multiple recursive generator with two components of order 3.
VSL_BRNG_MCG59	A 59-bit multiplicative congruential generator.
VSL_BRNG_WH	A set of 273 Wichmann-Hill combined multiplicative congruential generators.
VSL_BRNG_MT19937	A Mersenne Twister pseudorandom number generator.
VSL_BRNG_MT2203	A set of 6024 Mersenne Twister pseudorandom number generators.
VSL_BRNG_SFMT19937	A SIMD-oriented Fast Mersenne Twister pseudorandom number generator.
VSL_BRNG_SOBOL	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \le s \le 40$; user-defined dimensions are also available.
VSL_BRNG_NIEDERR	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \le s \le 318$; user-defined dimensions are also available.
VSL_BRNG_IABSTRACT	An abstract random number generator for integer arrays.
VSL_BRNG_DABSTRACT	An abstract random number generator for double precision floating-point arrays.
VSL_BRNG_SABSTRACT	An abstract random number generator for single precision floating-point arrays.
VSL_BRNG_NONDETERM	A non-deterministic random number generator.
VSL_BRNG_PHILOX4X32X10	A Philox4x32-10 counter-based pseudorandom number generator.
VSL_BRNG_ARS5	An ARS-5 counter-based pseudorandom number generator that uses instructions from the AES-NI set.

See VS Notes for detailed description.

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Random Streams

Random stream (or *stream*) is an abstract source of pseudo- and quasi-random sequences of uniform distribution. You can operate with stream state descriptors only. A stream state descriptor, which holds state descriptive information for a particular BRNG, is a necessary parameter in each routine of a distribution generator. Only the distribution generator routines operate with random streams directly. See VS Notes for details.

NOTE
Random streams associated with abstract basic random number generator are called the abstract random streams. See VS Notes for detailed description of abstract streams and their use.

You can create unlimited number of random streams by VS Service Routines like `NewStream` and utilize them in any distribution generator to get the sequence of numbers of given probability distribution. When they are no longer needed, the streams should be deleted calling service routine `DeleteStream`.

VS provides service functions `SaveStreamF` and `LoadStreamF` to save random stream descriptive data to a binary file and to read this data from a binary file respectively. See VS Notes for detailed description.

BRNG Data Types

FORTRAN 77:

```
INTEGER*4 vslstreamstate(2)
```

Fortran 90:

```
TYPEVSL_STREAM_STATEINTEGER*4 descriptor1INTEGER*4 descriptor2ENDTYPE VSL_STREAM_STATE
```

Error Reporting

VS RNG routines return status codes of the performed operation to report errors to the calling program. The application should perform error-related actions and/or recover from the error. The status codes are of integer type and have the following format:

`VSL_ERROR_<`*ERROR_NAME*> - indicates VS errors common for all VS domains.

`VSL_RNG_ERROR_<`*ERROR_NAME*> - indicates VS RNG errors.

VS RNG errors are of negative values while warnings are of positive values. The status code of zero value indicates successful completion of the operation: `VSL_ERROR_OK` (or synonymic `VSL_STATUS_OK`).

Status Codes

Status Code	Description
Common VSL	
`VSL_ERROR_OK`, `VSL_STATUS_OK`	No error, execution is successful.
`VSL_ERROR_BADARGS`	Input argument value is not valid.
`VSL_ERROR_CPU_NOT_SUPPORTED`	CPU version is not supported.
`VSL_ERROR_FEATURE_NOT_IMPLEMENTED`	Feature invoked is not implemented.
`VSL_ERROR_MEM_FAILURE`	System cannot allocate memory.
`VSL_ERROR_NULL_PTR`	Input pointer argument is NULL.
`VSL_ERROR_UNKNOWN`	Unknown error.
VS RNG Specific	
`VSL_RNG_ERROR_BAD_FILE_FORMAT`	File format is unknown.
`VSL_RNG_ERROR_BAD_MEM_FORMAT`	Descriptive random stream format is unknown.
`VSL_RNG_ERROR_BAD_NBITS`	The value in `NBits` field is bad.

Status Code	Description
VSL_RNG_ERROR_BAD_NSEEDS	The value in NSeeds field is bad.
VSL_RNG_ERROR_BAD_STREAM	The random stream is invalid.
VSL_RNG_ERROR_BAD_STREAM_STATE_SIZE	The value in StreamStateSize field is bad.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or >nmax.
VSL_RNG_ERROR_BAD_WORD_SIZE	The value in WordSize field is bad.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_RNG_ERROR_BRNGS_INCOMPATIBLE	Two BRNGs are not compatible for the operation.
VSL_RNG_ERROR_FILE_CLOSE	Error in closing the file.
VSL_RNG_ERROR_FILE_OPEN	Error in opening the file.
VSL_RNG_ERROR_FILE_READ	Error in reading the file.
VSL_RNG_ERROR_FILE_WRITE	Error in writing the file.
VSL_RNG_ERROR_INVALID_ABSTRACT_STREAM	The abstract random stream is invalid.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is not valid.
VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns zero as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator is exceeded.
VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support Skip-Ahead method.
VSL_RNG_ERROR_SKIPAHEADEX_UNSUPPORTED	BRNG does not support advanced Skip-Ahead method.
VSL_RNG_ERROR_UNSUPPORTED_FILE_VER	File format version is not supported.
VSL_RNG_ERROR_NONDETERM_NOT_SUPPORTED	Non-deterministic random number generator is not supported on the CPU running the application.
VSL_RNG_ERROR_NONDETERM_ NRETRIES_EXCEEDED	Number of retries to generate a random number using non-deterministic random number generator exceeds threshold (see Section 7.2.1.12 *Non-deterministic* in [VS Notes] for more details)
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

VS RNG Usage ModelIntel® oneMKL RNG Usage Model

A typical algorithm for VSoneMKL random number generators is as follows:

1. Create and initialize stream/streams. Functions `vslNewStream`, `vslNewStreamEx`, `vslCopyStream`, `vslCopyStreamState`, `vslLeapfrogStream`, `vslSkipAheadStream`, `vslSkipAheadStreamEx`.
2. Call one or more RNGs.
3. Process the output.
4. Delete the stream or streams with the function `vslDeleteStream`.

NOTE
You may reiterate steps 2-3. Random number streams may be generated for different threads.

The following example demonstrates generation of a random stream that is output of basic generator MT19937. The seed is equal to 777. The stream is used to generate 10,000 normally distributed random numbers in blocks of 1,000 random numbers with parameters *a* = 5 and *sigma* = 2. Delete the streams after completing the generation. The purpose of the example is to calculate the sample mean for normal distribution with the given parameters.

Example of VS RNG Usage

```
      include 'mkl_vsl.f90'

      program MKL_VSL_GAUSSIAN

      USE MKL_VSL_TYPE
      USE MKL_VSL

      real(kind=8) r(1000)  ! buffer for random numbers
      real(kind=8) s        ! average
      real(kind=8) a, sigma ! parameters of normal distribution

      TYPE (VSL_STREAM_STATE) :: stream

      integer(kind=4) errcode
      integer(kind=4) i,j
      integer brng,method,seed,n

      n = 1000
      s = 0.0
      a = 5.0
      sigma  = 2.0
      brng=VSL_BRNG_MT19937
      method=VSL_RNG_METHOD_GAUSSIAN_ICDF
      seed=777

!     ***** Initializing *****
      errcode=vslnewstream( stream, brng,  seed )

!     ***** Generating *****
      do i = 1,10
```

```
          errcode=vdrnggaussian( method, stream, n, r, a, sigma )
          do j = 1, 1000
              s = s + r(j)
          end do
      end do

      s = s / 10000.0

!     ***** Deinitialize *****
      errcode=vsldeletestream( stream )

!     ***** Printing results *****
      print *,"Sample mean of normal distribution = ", s

      end
```

Additionally, examples that demonstrate usage of VS random number generators are available in:

`${MKL}/examples/vslf/source`

Service Routines

Stream handling comprises routines for creating, deleting, or copying the streams and getting the index of a basic generator. A random stream can also be saved to and then read from a binary file. Table "Service Routines" lists all available service routines

Service Routines

Routine	Short Description
vslNewStream	Creates and initializes a random stream.
vslNewStreamEx	Creates and initializes a random stream for the generators with multiple initial conditions.
vsliNewAbstractStream	Creates and initializes an abstract random stream for integer arrays.
vsldNewAbstractStream	Creates and initializes an abstract random stream for double precision floating-point arrays.
vslsNewAbstractStream	Creates and initializes an abstract random stream for single precision floating-point arrays.
vslDeleteStream	Deletes previously created stream.
vslCopyStream	Copies a stream to another stream.
vslCopyStreamState	Creates a copy of a random stream state.
vslSaveStreamF	Writes a stream to a binary file.
vslLoadStreamF	Reads a stream from a binary file.
vslSaveStreamM	Writes a random stream descriptive data, including state, to a memory buffer.
vslLoadStreamM	Creates a new stream and reads stream descriptive data, including state, from the memory buffer.
vslGetStreamSize	Computes size of memory necessary to hold the random stream.

Routine	Short Description
vslLeapfrogStream	Initializes the stream by the leapfrog method to generate a subsequence of the original sequence.
vslSkipAheadStream	Initializes the stream by the skip-ahead method.
vslSkipAheadStreamEx	Initializes the stream by the advanced skip-ahead method.
vslGetStreamStateBrng	Obtains the index of the basic generator responsible for the generation of a given random stream.
vslGetNumRegBrngs	Obtains the number of currently registered basic generators.

Most of the generator-based work comprises three basic steps:

1. Creating and initializing a stream (vslNewStream, vslNewStreamEx, vslCopyStream, vslCopyStreamState, vslLeapfrogStream, vslSkipAheadStream, vslSkipAheadStreamEx).
2. Generating random numbers with given distribution, see Distribution Generators.
3. Deleting the stream (vslDeleteStream).

Note that you can concurrently create multiple streams and obtain random data from one or several generators by using the stream state. You must use the vslDeleteStream function to delete all the streams afterwards.

vslNewStream

Creates and initializes a random stream.

Syntax

```
status = vslnewstream( stream, brng, seed )
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
brng	INTEGER, INTENT(IN)	Index of the basic generator to initialize the stream. See Table Values of *brng* parameter for specific value.
seed	INTEGER, INTENT(IN)	Initial condition of the stream. In the case of a quasi-random number generator seed parameter is used to set the dimension. If the dimension is greater than the dimension that brng can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), INTENT(OUT)	Stream state descriptor

Description

For a basic generator with number *brng*, this function creates a new stream and initializes it with a 32-bit seed. The seed is an initial value used to select a particular sequence generated by the basic generator *brng*. The function is also applicable for generators with multiple initial conditions. Use this function to create and

initialize a new stream with a 32-bit seed only. If you need to provide multiple initial conditions such as several 32-bit or wider seeds, use the function vslNewStreamEx. See VS Notes for a more detailed description of stream initialization for different basic generators.

NOTE
This function is not applicable for abstract basic random number generators. Please use `vsliNewAbstractStream`, `vslsNewAbstractStream` or `vsldNewAbstractStream` to utilize integer, single-precision or double-precision external random data respectively.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.
Notice revision #20201201

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_RNG_ERROR_INVALID_BRNG_INDEX`	BRNG index is invalid.
`VSL_ERROR_MEM_FAILURE`	System cannot allocate memory for *stream*.
`VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED`	Non-deterministic random number generator is not supported.
`VSL_RNG_ERROR_ARS5_NOT_SUPPORTED`	ARS-5 random number generator is not supported on the CPU running the application.

vslNewStreamEx

Creates and initializes a random stream for generators with multiple initial conditions.

Syntax

```
status = vslnewstreamex( stream, brng, n, params )
```

Include Files

- `mkl.fi`, `mkl_vsl.f90`

Input Parameters

Name	Type	Description
brng	`INTEGER`, `INTENT(IN)`	Index of the basic generator to initialize the stream. See Table "Values of *brng* parameter" for specific value.
n	`INTEGER`, `INTENT(IN)`	Number of initial conditions contained in *params*
params	`INTEGER(KIND=4)`, `INTENT(IN)`	Array of initial conditions necessary for the basic generator *brng* to initialize the stream. In the case of a quasi-random number generator only the first element in *params*

Name	Type	Description
		parameter is used to set the dimension. If the dimension is greater than the dimension that *brng* can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), INTENT(OUT)	Stream state descriptor

Description

The vslNewStreamEx function provides an advanced tool to set the initial conditions for a basic generator if its input arguments imply several initialization parameters. Initial values are used to select a particular sequence generated by the basic generator *brng*. Whenever possible, use vslNewStream, which is analogous to vslNewStreamEx except that it takes only one 32-bit initial condition. In particular, vslNewStreamEx may be used to initialize the state table in Generalized Feedback Shift Register Generators (GFSRs). A more detailed description of this issue can be found in VS Notes.

This function is also used to pass user-defined initialization parameters of quasi-random number generators into the library. See VS Notes for the format for their passing and registration in VS.

NOTE
This function is not applicable for abstract basic random number generators. Please use vsliNewAbstractStream, vslsNewAbstractStream or vsldNewAbstractStream to utilize integer, single-precision or double-precision external random data respectively.

Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

Notice revision #20201201

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for *stream*.
VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED	Non-deterministic random number generator is not supported.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vsliNewAbstractStream

Creates and initializes an abstract random stream for integer arrays.

Syntax

status = vslinewabstractstream(*stream*, *n*, *ibuf*, *icallback*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Size of the array *ibuf*
ibuf	INTEGER(KIND=4), INTENT(IN)	Array of *n* 32-bit integers
icallback	See *Note* below	Address of the callback function used for *ibuf* update

NOTE
Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION IUPDATEFUNC( stream, n, ibuf, nmin, nmax, idx )
INTEGER*4 stream(2)
INTEGER n
INTEGER*4 ibuf(n)
INTEGER nmin
INTEGER nmax
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION IUPDATEFUNC[C]( stream, n, ibuf, nmin, nmax, idx )
TYPE(VSL_STREAM_STATE),POINTER :: stream[reference]
INTEGER(KIND=4),INTENT(IN)     :: n[reference]
INTEGER(KIND=4),INTENT(OUT)    :: ibuf[reference](0:n-1)
INTEGER(KIND=4),INTENT(IN)     :: nmin[reference]
INTEGER(KIND=4),INTENT(IN)     :: nmax[reference]
INTEGER(KIND=4),INTENT(IN)     :: idx[reference]
```

The callback function returns the number of elements in the array actually updated by the function.Table `icallback` Callback Function Parameters gives the description of the callback function parameters.

icallback Callback Function Parameters

Parameters	Short Description
stream	Abstract random stream descriptor
n	Size of *ibuf*
ibuf	Array of random numbers associated with the stream *stream*

Parameters	Short Description
nmin	Minimal quantity of numbers to update
nmax	Maximal quantity of numbers that can be updated
idx	Position in cyclic buffer *ibuf* to start update 0≤*idx*<*n*.

Output Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), TINTENT(OUT)	Descriptor of the stream state structure

Description

The vsliNewAbstractStream function creates a new abstract stream and associates it with an integer array *ibuf* and your callback function *icallback* that is intended for updating of *ibuf* content.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BADARGS	Parameter *n* is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for *stream*.
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

vsldNewAbstractStream

Creates and initializes an abstract random stream for double precision floating-point arrays.

Syntax

status = vsldnewabstractstream(*stream*, *n*, *dbuf*, *a*, *b*, *dcallback*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Size of the array *dbuf*
dbuf	REAL(KIND=8), INTENT(IN)	Array of *n* double precision floating-point random numbers with uniform distribution over interval (a,b)
a	REAL(KIND=8), INTENT(IN)	Left boundary a
b	REAL(KIND=8), INTENT(IN)	Right boundary b
dcallback	See *Note* below	Address of the callback function used for update of the array *dbuf*

Output Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), INTENT(OUT)	Descriptor of the stream state structure

NOTE
Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION DUPDATEFUNC( stream, n, dbuf, nmin, nmax, idx )
INTEGER*4 stream(2)
INTEGER n
DOUBLE PRECISION dbuf(n)
INTEGER nmin
INTEGER nmax
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION DUPDATEFUNC[C]( stream, n, dbuf, nmin, nmax, idx )
TYPE(VSL_STREAM_STATE),POINTER   :: stream[reference]
INTEGER(KIND=4),INTENT(IN)       :: n[reference]
REAL(KIND=8),INTENT(OUT)         :: dbuf[reference](0:n-1)
INTEGER(KIND=4),INTENT(IN)       :: nmin[reference]
INTEGER(KIND=4),INTENT(IN)       :: nmax[reference]
INTEGER(KIND=4),INTENT(IN)       :: idx[reference]
```

The callback function returns the number of elements in the array actually updated by the function.Table `dcallback` Callback Function Parameters gives the description of the callback function parameters.

dcallback Callback Function Parameters

Parameters	Short Description
stream	Abstract random stream descriptor
n	Size of *dbuf*
dbuf	Array of random numbers associated with the stream *stream*
nmin	Minimal quantity of numbers to update
nmax	Maximal quantity of numbers that can be updated
idx	Position in cyclic buffer *dbuf* to start update $0 \le idx < n$.

Description

The `vsldNewAbstractStream` function creates a new abstract stream for double precision floating-point arrays with random numbers of the uniform distribution over interval (`a`,`b`). The function associates the stream with a double precision array *dbuf* and your callback function *dcallback* that is intended for updating of *dbuf* content.

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`	Indicates no error, execution is successful.

VSL_ERROR_BADARGS	Parameter *n* is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for *stream*.
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

vslsNewAbstractStream

Creates and initializes an abstract random stream for single precision floating-point arrays.

Syntax

status = vslsnewabstractstream(*stream*, *n*, *sbuf*, *a*, *b*, *scallback*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
n	INTEGER, INTENT(IN)	Size of the array *sbuf*
sbuf	REAL(KIND=4), INTENT(IN)	Array of *n* single precision floating-point random numbers with uniform distribution over interval (a,b)
a	REAL(KIND=4), INTENT(IN)	Left boundary a
b	REAL(KIND=4), INTENT(IN)	Right boundary b
scallback	See *Note* below	Address of the callback function used for update of the array *sbuf*

Output Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), INTENT(OUT)	Descriptor of the stream state structure

NOTE
Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION SUPDATEFUNC( stream, n, ibuf, nmin, nmax, idx )
INTEGER*4 stream(2)
INTEGER n
REAL sbuf(n)
INTEGER nmin
INTEGER nmax
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION SUPDATEFUNC[C]( stream, n, sbuf, nmin, nmax, idx )
TYPE(VSL_STREAM_STATE),POINTER :: stream[reference]
INTEGER(KIND=4),INTENT(IN)     :: n[reference]
REAL(KIND=4),   INTENT(OUT)    :: sbuf[reference](0:n-1)
INTEGER(KIND=4),INTENT(IN)     :: nmin[reference]
INTEGER(KIND=4),INTENT(IN)     :: nmax[reference]
INTEGER(KIND=4),INTENT(IN)     :: idx[reference]
```

The callback function returns the number of elements in the array actually updated by the function.Table `scallback` Callback Function Parameters gives the description of the callback function parameters.

scallback Callback Function Parameters

Parameters	Short Description
stream	Abstract random stream descriptor
n	Size of *sbuf*
sbuf	Array of random numbers associated with the stream *stream*
nmin	Minimal quantity of numbers to update
nmax	Maximal quantity of numbers that can be updated
idx	Position in cyclic buffer *sbuf* to start update $0 \le idx < n$.

Description

The `vslsNewAbstractStream` function creates a new abstract stream for single precision floating-point arrays with random numbers of the uniform distribution over interval (`a`,`b`). The function associates the stream with a single precision array *sbuf* and your callback function *scallback* that is intended for updating of *sbuf* content.

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_BADARGS`	Parameter *n* is not positive.
`VSL_ERROR_MEM_FAILURE`	System cannot allocate memory for *stream*.
`VSL_ERROR_NULL_PTR`	Either buffer or callback function parameter is a `NULL` pointer.

vslDeleteStream

Deletes a random stream.

Syntax

```
status = vsldeletestream( stream )
```

Include Files

- mkl.fi, mkl_vsl.f90

Input/Output Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), INTENT(OUT)	Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the descriptor becomes invalid.

Description

The function deletes the random stream created by one of the initialization functions.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* parameter is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.

vslCopyStream

Creates a copy of a random stream.

Syntax

```
status = vslcopystream( newstream, srcstream )
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
srcstream	TYPE(VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream to be copied

Output Parameters

Name	Type	Description
newstream	TYPE(VSL_STREAM_STATE), INTENT(OUT)	Copied random stream descriptor

Description

The function creates an exact copy of *srcstream* and stores its descriptor to *newstream*.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*srcstream* parameter is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*srcstream* is not a valid random stream.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for *newstream*.

vslCopyStreamState

Creates a copy of a random stream state.

Syntax

status = vslcopystreamstate(*deststream*, *srcstream*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
srcstream	TYPE(VSL_STREAM_STATE), INTENT(IN)	Descriptor of the destination stream where the state of *scrstream* stream is copied

Output Parameters

Name	Type	Description
deststream	TYPE(VSL_STREAM_STATE), INTENT(OUT)	Descriptor of the stream with the state to be copied

Description

The vslCopyStreamState function copies a stream state from *srcstream* to the existing *deststream* stream. Both the streams should be generated by the same basic generator. An error message is generated when the index of the BRNG that produced *deststream* stream differs from the index of the BRNG that generated *srcstream* stream.

Unlike vslCopyStream function, which creates a new stream and copies both the stream state and other data from *srcstream*, the function vslCopyStreamState copies only *srcstream* stream state data to the generated *deststream* stream.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either *srcstream* or *deststream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	Either *srcstream* or *deststream* is not a valid random stream.
VSL_RNG_ERROR_BRNGS_INCOMPATIBLE	BRNG associated with *srcstream* is not compatible with BRNG associated with *deststream*.

vslSaveStreamF

Writes random stream descriptive data, including stream state, to binary file.

Syntax

```
errstatus = vslsavestreamf( stream, fname )
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), INTENT(IN)	Random stream to be written to the file
fname	CHARACTER(*), INTENT(IN)	File name specified as a C-style null-terminated string

Output Parameters

Name	Type	Description
errstatus	INTEGER	Error status of the operation

Description

The vslSaveStreamF function writes the random stream descriptive data, including the stream state, to the binary file. Random stream descriptive data is saved to the binary file with the name *fname*. The random stream *stream* must be a valid stream created by vslNewStream-like or vslCopyStream-like service routines. If the stream cannot be saved to the file, *errstatus* has a non-zero value. The random stream can be read from the binary file using the vslLoadStreamF function.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either *fname* or *stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_RNG_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_RNG_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.

vslLoadStreamF

Creates new stream and reads stream descriptive data, including stream state, from binary file.

Syntax

```
errstatus = vslloadstreamf( stream, fname )
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
fname	CHARACTER(*), INTENT(IN)	File name specified as a C-style null-terminated string

Output Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), INTENT(OUT)	Descriptor of a new random stream
errstatus	INTEGER	Error status of the operation

Description

The vslLoadStreamF function creates a new stream and reads stream descriptive data, including the stream state, from the binary file. A new random stream is created using the stream descriptive data from the binary file with the name *fname*. If the stream cannot be read (for example, an I/O error occurs or the file format is invalid), *errstatus* has a non-zero value. To save random stream to the file, use vslSaveStreamF function.

Caution
Calling vslLoadStreamF with a previously initialized *stream* pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling vslLoadStreamF, you should call the vslDeleteStream function first to deallocate the resources.

Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

Notice revision #20201201

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*fname* is a NULL pointer.
VSL_RNG_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_RNG_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_RNG_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.
VSL_RNG_ERROR_BAD_FILE_FORMAT	Unknown file format.
VSL_RNG_ERROR_UNSUPPORTED_FILE_VER	File format version is unsupported.

VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED	Non-deterministic random number generator is not supported.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vslSaveStreamM

Writes random stream descriptive data, including stream state, to a memory buffer.

Syntax

```
errstatus = vslsavestreamm( stream, memptr )
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), INTENT(IN)	Random stream to be written to the memory
memptr	INTEGER(KIND=1), DIMENSION(*), INTENT(IN)	Memory buffer to save random stream descriptive data to

Output Parameters

Name	Type	Description
errstatus	INTEGER	Error status of the operation

Description

The vslSaveStreamM function writes the random stream descriptive data, including the stream state, to the memory at *memptr*. Random stream *stream* must be a valid stream created by vslNewStream-like or vslCopyStream-like service routines. The *memptr* parameter must be a valid pointer to the memory of size sufficient to hold the random stream *stream*. Use the service routine vslGetStreamSize to determine this amount of memory.

If the stream cannot be saved to the memory, *errstatus* has a non-zero value. The random stream can be read from the memory pointed by *memptr* using the vslLoadStreamM function.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either *memptr* or *stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is a NULL pointer.

vslLoadStreamM

Creates a new stream and reads stream descriptive data, including stream state, from the memory buffer.

Syntax

```
errstatus = vslloadstreamm( stream, memptr )
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
memptr	INTEGER(KIND=1), DIMENSION(*), INTENT(IN)	Memory buffer to load random stream descriptive data from

Output Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), INTENT(OUT)	Descriptor of a new random stream
errstatus	INTEGER	Error status of the operation

Description

The vslLoadStreamM function creates a new stream and reads stream descriptive data, including the stream state, from the memory buffer. A new random stream is created using the stream descriptive data from the memory pointer by *memptr*. If the stream cannot be read (for example, *memptr* is invalid), *errstatus* has a non-zero value. To save random stream to the memory, use vslSaveStreamM function. Use the service routine vslGetStreamSize to determine the amount of memory sufficient to hold the random stream.

Caution
Calling LoadStreamM with a previously initialized *stream* pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling vslLoadStreamM, you should call the vslDeleteStream function first to deallocate the resources.

Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

Notice revision #20201201

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*memptr* is a NULL pointer.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.
VSL_RNG_ERROR_BAD_MEM_FORMAT	Descriptive random stream format is unknown.

VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED	Non-deterministic random number generator is not supported.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vslGetStreamSize

Computes size of memory necessary to hold the random stream.

Syntax

```
memsize = vslgetstreamsize( stream )
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), INTENT(IN)	Random stream

Output Parameters

Name	Type	Description
memsize	INTEGER	Amount of memory in bytes necessary to hold descriptive data of random stream *stream*

Description

The vslGetStreamSize function returns the size of memory in bytes which is necessary to hold the given random stream. Use the output of the function to allocate the buffer to which you will save the random stream by means of the vslSaveStreamM function.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_BAD_STREAM	*stream* is a NULL pointer.

vslLeapfrogStream

Initializes a stream using the leapfrog method.

Syntax

```
status = vslleapfrogstream( stream, k, nstreams )
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream to which leapfrog method is applied
k	INTEGER, INTENT(IN)	Index of the computational node, or stream number
nstreams	INTEGER, INTENT(IN)	Largest number of computational nodes, or stride

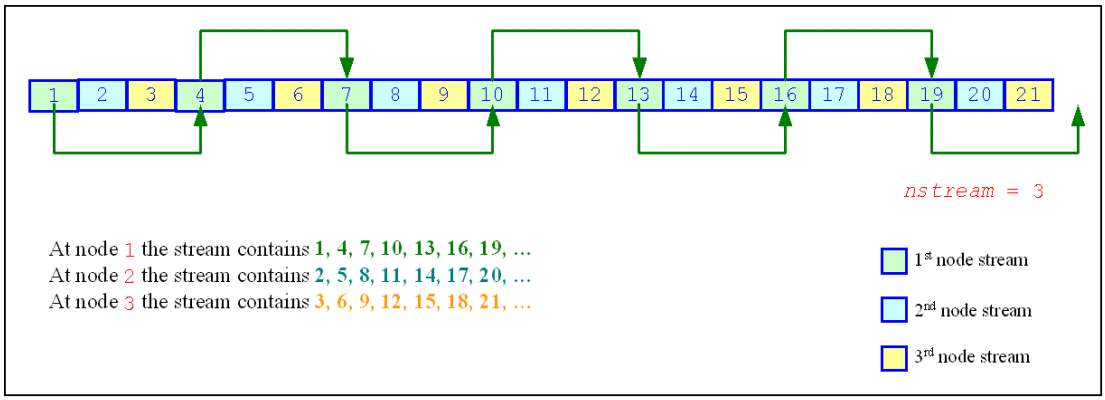
Description

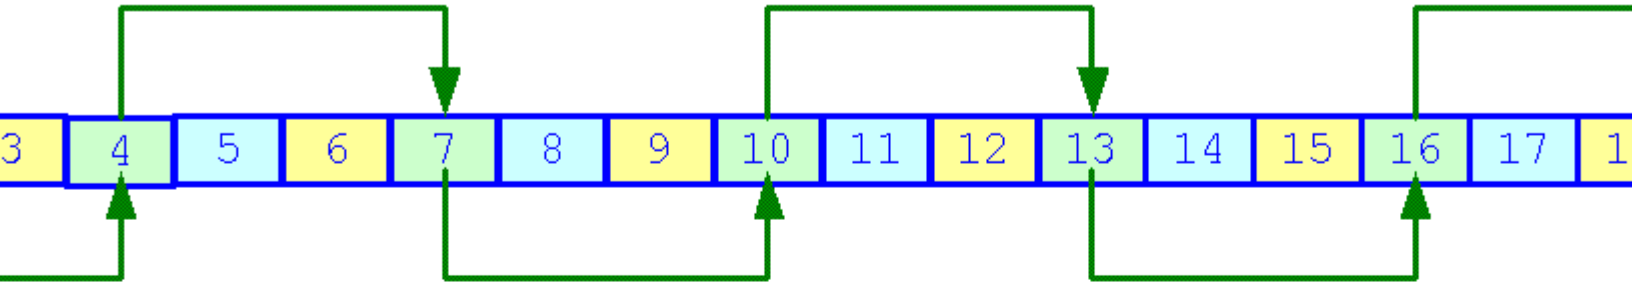
The vslLeapfrogStream function generates random numbers in a random stream with non-unit stride. This feature is particularly useful in distributing random numbers from the original stream across the *nstreams* buffers without generating the original random sequence with subsequent manual distribution.

One of the important applications of the leapfrog method is splitting the original sequence into non-overlapping subsequences across *nstreams* computational nodes. The function initializes the original random stream (see Figure "Leapfrog Method") to generate random numbers for the computational node k, $0 \le k < nstreams$, where *nstreams* is the largest number of computational nodes used.

__border__top

Leapfrog Method





he stream contains 1, 4, 7, 10, 13, 16, 19, ...
he stream contains 2, 5, 8, 11, 14, 17, 20, ...
he stream contains 3, 6, 9, 12, 15, 18, 21, ...

The leapfrog method is supported only for those basic generators that allow splitting elements by the leapfrog method, which is more efficient than simply generating them by a generator with subsequent manual distribution across computational nodes. See VS Notes for details.

For quasi-random basic generators, the leapfrog method allows generating individual components of quasi-random vectors instead of whole quasi-random vectors. In this case *nstreams* parameter should be equal to the dimension of the quasi-random vector while *k* parameter should be the index of a component to be generated (0 ≤*k* < *nstreams*). Other parameters values are not allowed.

The following code illustrates the initialization of three independent streams using the leapfrog method:

Code for Leapfrog Method

```
...
TYPE(VSL_STREAM_STATE)   ::stream1
TYPE(VSL_STREAM_STATE)   ::stream2
TYPE(VSL_STREAM_STATE)   ::stream3

! Creating 3 identical streams
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)
status = vslcopystream(stream2, stream1)
status = vslcopystream(stream3, stream1)

! Leapfrogging the streams
status = vslleapfrogstream(stream1, 0, 3)
status = vslleapfrogstream(stream2, 1, 3)
status = vslleapfrogstream(stream3, 2, 3)

! Generating random numbers
...
! Deleting the streams
status = vsldeletestream(stream1)
status = vsldeletestream(stream2)
status = vsldeletestream(stream3)
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.

vslSkipAheadStream

Initializes a stream using the block-splitting method.

Syntax

status = vslskipaheadstream(*stream*, *nskip*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

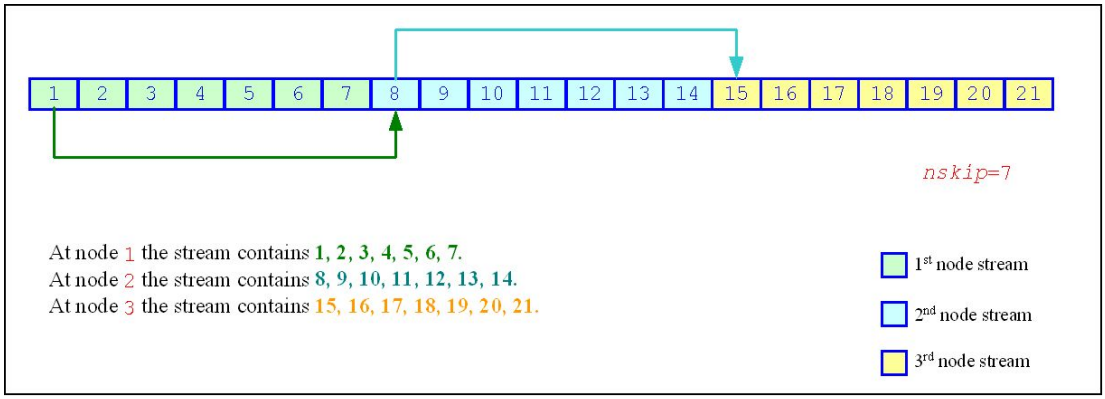
Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream to which block-splitting method is applied
nskip	INTEGER(KIND=8), INTENT(IN)	Number of skipped elements

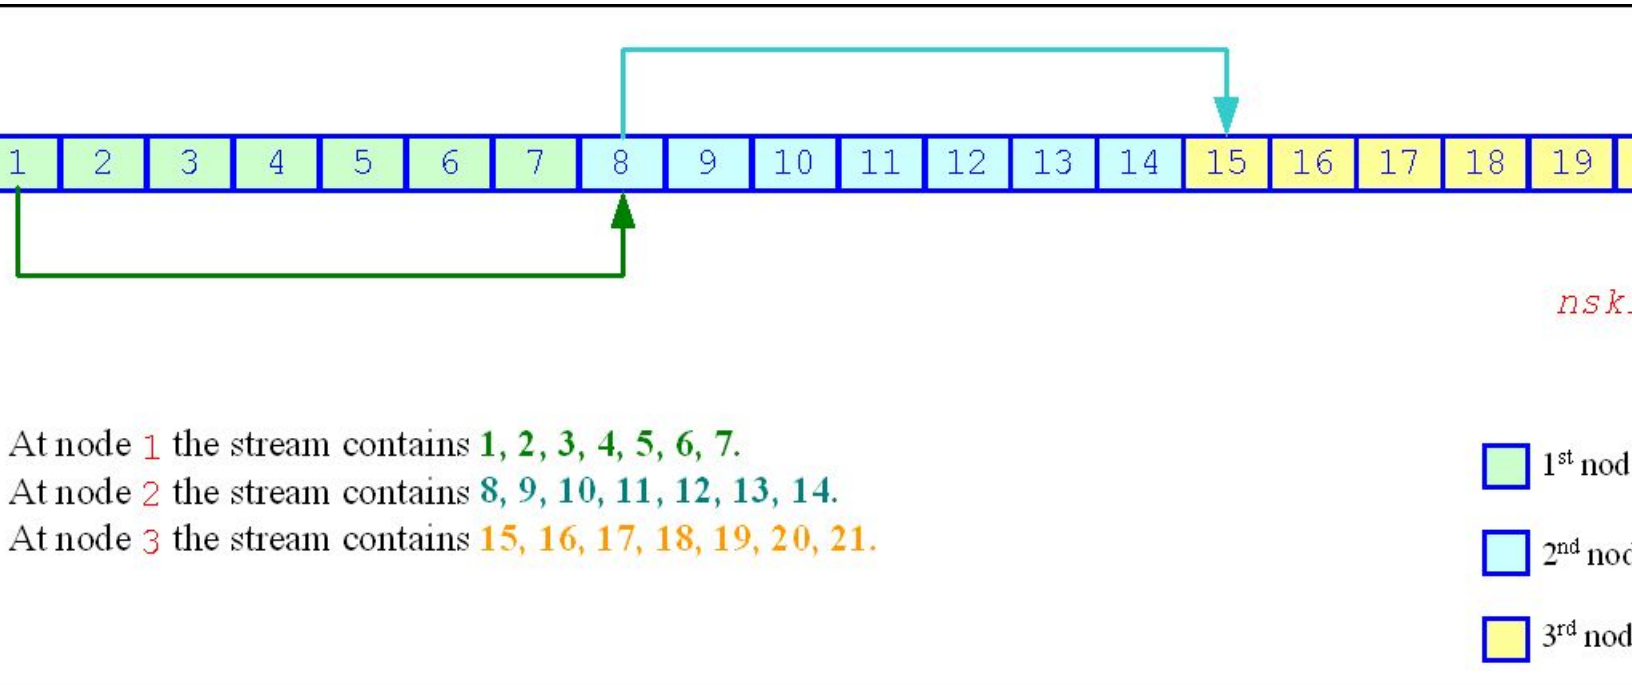
Description

The `vslSkipAheadStream` function skips a given number of elements in a random stream. This feature is particularly useful in distributing random numbers from original random stream across different computational nodes. If the largest number of random numbers used by a computational node is *nskip*, then the original random sequence may be split by `vslSkipAheadStream` into non-overlapping blocks of *nskip* size so that each block corresponds to the respective computational node. The number of computational nodes is unlimited. This method is known as the block-splitting method or as the skip-ahead method. (see Figure "Block-Splitting Method").

__border__top

Block-Splitting Method





The skip-ahead method is supported only for those basic generators that allow skipping elements by the skip-ahead method, which is more efficient than simply generating them by generator with subsequent manual skipping. See VS Notes for details.

Please note that for quasi-random basic generators the skip-ahead method works with components of quasi-random vectors rather than with whole quasi-random vectors. Therefore, to skip NS quasi-random vectors, set the *nskip* parameter equal to the NS*DIMEN, where DIMEN is the dimension of the quasi-random vector. If this operation results in exceeding the period of the quasi-random number generator, which is 2^{32}-1, the library returns the VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED error code.

The following code illustrates how to initialize three independent streams using the vslSkipAheadStream function:

Code for Block-Splitting Method

```
...
type(VSL_STREAM_STATE)  ::stream1
type(VSL_STREAM_STATE)  ::stream2
type(VSL_STREAM_STATE)  ::stream3

! Creating the 1st stream
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)

! Skipping ahead by 7 elements the 2nd stream
status = vslcopystream(stream2, stream1);
status = vslskipaheadstream(stream2, 7);

! Skipping ahead by 7 elements the 3rd stream
status = vslcopystream(stream3, stream2);
status = vslskipaheadstream(stream3, 7);

! Generating random numbers
...
! Deleting the streams
status = vsldeletestream(stream1)
status = vsldeletestream(stream2)
status = vsldeletestream(stream3)
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support the Skip-Ahead method.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the quasi-random number generator is exceeded.

vslSkipAheadStreamEx

Initializes a stream using the block-splitting method with partitioned number of skipped elements.

Syntax

status = vslskipAheadstreamEx(*stream*, *n*, *nskip*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), INTENT(IN)	Pointer to the stream state structure to which block-splitting method is applied
n	INTEGER, INTENT(IN)	Number of summands in *nskip*
nskip	INTEGER(KIND=8), INTENT(IN)	Partitioned number of skipped elements

Description

The vslSkipAheadStreamEx function skips a given number of elements in a random stream. This feature is particularly useful in distributing random numbers from original random stream across different computational nodes. If the largest number of random numbers used by a computational node is *nskip*, then the original random sequence may be split by vslSkipAheadStreamEx into non-overlapping blocks of *nskip* size so that each block corresponds to the respective computational node. The number of computational nodes is unlimited. This method is known as the block-splitting method or as the skip-ahead method.

Use this function when the number of elements to skip in a random stream is greater than 2^{63}. Prior calls to the function represent the number of skipped elements with array of size *n* as shown below:

nskip[0]+ *nskip*[1]*2^{64}+*nskip*[2]* 2^{128}+ … +*nskip*[n-1]*$2^{(64*(n-1))}$;

When the number of skipped elements is less than 2^{63} you can use either vslSkipAheadtreamEx or vslSkipAheadStream. The following code illustrates how to initialize three independent streams using the vslSkipAheadStreamEx function:

```
...
type(VSL_STREAM_STATE) ::stream1 type(VSL_STREAM_STATE) ::stream2
type(VSL_STREAM_STATE) ::stream3

! Creating the 1st stream
status = vslnewstream(stream1, VSL_BRNG_MRG32K3A, 174)

! To skip 2^64 elements in the random stream skipaheadstreamEx(nskip) function should !    be
called with nskip represented as nskip = 2^64 = 0 + 1 * 2^64
integer(kind=8) nskip(2)
nskip(1) = 0
nskip(2) = 1

! Skipping ahead by 2^64 elements the 2nd stream
status = vslcopystream(stream2, stream1)
status = vslskipaheadstreamex (stream2, 2, nskip)

! Skipping ahead by 2^64 elements the 3rd stream
status = vslcopystream(stream3, stream2)
status = vslskipaheadstreamex (stream3, 2, nskip)

! Generating random numbers
...

! Deleting the streams
status = vsldeletestream(stream1)
status = vsldeletestream(stream2)
status = vsldeletestream(stream3)
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_SKIPAHEADEX_UNSUPPORTED	BRNG does not support the advanced Skip-Ahead method.

vslGetStreamStateBrng

Returns index of a basic generator used for generation of a given random stream.

Syntax

```
brng = vslgetstreamstatebrng( stream )
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
stream	TYPE(VSL_STREAM_STATE), TINTENT(IN)	Descriptor of the stream state

Output Parameters

Name	Type	Description
brng	INTEGER	Index of the basic generator assigned for the generation of *stream* ; negative in case of an error

Description

The vslGetStreamStateBrng function retrieves the index of a basic generator used for generation of a given random stream.

Return Values

VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.

vslGetNumRegBrngs

Obtains the number of currently registered basic generators.

Syntax

```
nregbrngs = vslgetnumregbrngs( )
```

Include Files

- mkl.fi, mkl_vsl.f90

Output Parameters

Name	Type	Description
nregbrngs	INTEGER	Number of basic generators registered at the moment of the function call

Description

The `vslGetNumRegBrngs` function obtains the number of currently registered basic generators. Whenever user registers a user-designed basic generator, the number of registered basic generators is incremented. The maximum number of basic generators that can be registered is determined by the `VSL_MAX_REG_BRNGS` parameter.

Distribution Generators

oneMKLVS routines are used to generate random numbers with different types of distribution. Each function group is introduced below by the type of underlying distribution and contains a short description of its functionality, as well as specifications of the call sequence and the explanation of input and output parameters. Table "Continuous Distribution Generators" and Table "Discrete Distribution Generators" list the random number generator routines with data types and output distributions, and sets correspondence between data types of the generator routines and the basic random number generators.

Continuous Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
vRngUniform	s, d	s, d	Uniform continuous distribution on the interval [*a*,*b*)
vRngGaussian	s, d	s, d	Normal (Gaussian) distribution
vRngGaussianMV	s, d	s, d	Normal (Gaussian) multivariate distribution
vRngExponential	s, d	s, d	Exponential distribution
vRngLaplace	s, d	s, d	Laplace distribution (double exponential distribution)
vRngWeibull	s, d	s, d	Weibull distribution
vRngCauchy	s, d	s, d	Cauchy distribution
vRngRayleigh	s, d	s, d	Rayleigh distribution
vRngLognormal	s, d	s, d	Lognormal distribution
vRngGumbel	s, d	s, d	Gumbel (extreme value) distribution
vRngGamma	s, d	s, d	Gamma distribution
vRngBeta	s, d	s, d	Beta distribution
vRngChiSquare	s, d	s, d	Chi-Square distribution

Discrete Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
vRngUniform	i	d	Uniform discrete distribution on the interval [*a*,*b*)
vRngUniformBits	i	i	Underlying BRNG integer recurrence
vRngUniformBits32	i	i	Uniformly distributed bits in 32-bit chunks
vRngUniformBits64	i	i	Uniformly distributed bits in 64-bit chunks
vRngBernoulli	i	s	Bernoulli distribution
vRngGeometric	i	s	Geometric distribution
vRngBinomial	i	d	Binomial distribution
vRngHypergeometric	i	d	Hypergeometric distribution
vRngPoisson	i	s (for VSL_RNG_METHOD_POISSON_POISNORM) s (for distribution parameter $\lambda \geq 27$) and d (for $\lambda < 27$) (for VSL_RNG_METHOD_POISSON_PTPE)	Poisson distribution
vRngPoisson	i	s	Poisson distribution with varying mean
vRngNegBinomial	i	d	Negative binomial distribution, or Pascal distribution
vRngMultinomial	i	d	Multinomial distribution

Modes of random number generation

The library provides two modes of random number generation, accurate and fast. Accurate generation mode is intended for the applications that are highly demanding to accuracy of calculations. When used in this mode, the generators produce random numbers lying completely within definitional domain for all values of the distribution parameters. For example, random numbers obtained from the generator of continuous distribution that is uniform on interval [*a*,*b*] belong to this interval irrespective of what *a* and *b* values may be. Fast mode provides high performance of generation and also guarantees that generated random numbers belong to the definitional domain except for some specific values of distribution parameters. The generation mode is set by specifying relevant value of the method parameter in generator routines. List of distributions that support accurate mode of generation is given in the table below.

Distribution Generators Supporting Accurate Mode

Type of Distribution	Data Types
vRngUniform	s, d

Type of Distribution	Data Types
vRngExponential	s, d
vRngWeibull	s, d
vRngRayleigh	s, d
vRngLognormal	s, d
vRngGamma	s, d
vRngBeta	s, d

See additional details about accurate and fast mode of random number generation in VS Notes.

New method names

The current version of oneMKL has a modified structure of VS RNG method names. (SeeRNG Naming Conventions for details.) The old names are kept for backward compatibility. The tables below set correspondence between the new and legacy method names for VS random number generators.

Method Names for Continuous Distribution Generators

RNG	Legacy Method Name	New Method Name
vRngUniform	VSL_METHOD_SUNIFORM_STD, VSL_METHOD_DUNIFORM_STD, VSL_METHOD_SUNIFORM_STD_ACCURATE, VSL_METHOD_DUNIFORM_STD_ACCURATE	VSL_RNG_METHOD_UNIFORM_STD, VSL_RNG_METHOD_UNIFORM_STD_ACCURATE
vRngGaussian	VSL_METHOD_SGAUSSIAN_BOXMULLER, VSL_METHOD_SGAUSSIAN_BOXMULLER2, VSL_METHOD_SGAUSSIAN_ICDF, VSL_METHOD_DGAUSSIAN_BOXMULLER, VSL_METHOD_DGAUSSIAN_BOXMULLER2, VSL_METHOD_DGAUSSIAN_ICDF	VSL_RNG_METHOD_GAUSSIAN_BOXMULLER, VSL_RNG_METHOD_GAUSSIAN_BOXMULLER2, VSL_RNG_METHOD_GAUSSIAN_ICDF
vRngGaussianMV	VSL_METHOD_SGAUSSIANMV_BOXMULLER, VSL_METHOD_SGAUSSIANMV_BOXMULLER2, VSL_METHOD_SGAUSSIANMV_ICDF, VSL_METHOD_DGAUSSIANMV_BOXMULLER, VSL_METHOD_DGAUSSIANMV_BOXMULLER2, VSL_METHOD_DGAUSSIANMV_ICDF	VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER , VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER 2, VSL_RNG_METHOD_GAUSSIANMV_ICDF
vRngExponential	VSL_METHOD_SEXPONENTIAL_ICDF, VSL_METHOD_DEXPONENTIAL_ICDF, VSL_METHOD_SEXPONENTIAL_ICDF_ACCUR ATE, VSL_METHOD_DEXPONENTIAL_ICDF_ACCUR ATE	VSL_RNG_METHOD_EXPONENTIAL_ICDF, VSL_RNG_METHOD_EXPONENTIAL_ICDF_ACC URATE
vRngLaplace	VSL_METHOD_SLAPLACE_ICDF, VSL_METHOD_DLAPLACEL_ICDF	VSL_RNG_METHOD_LAPLACE_ICDF
vRngWeibull	VSL_METHOD_SWEIBULL_ICDF, VSL_METHOD_DWEIBULL_ICDF, VSL_METHOD_SWEIBULL_ICDF_ACCURATE, VSL_METHOD_DWEIBULL_ICDF_ACCURATE	VSL_RNG_METHOD_WEIBULL_ICDF, VSL_RNG_METHOD_WEIBULL_ICDF_ACCURAT E

RNG	Legacy Method Name	New Method Name
vRngCauchy	VSL_METHOD_SCAUCHY_ICDF, VSL_METHOD_DCAUCHY_ICDF	VSL_RNG_METHOD_CAUCHY_ICDF
vRngRayleigh	VSL_METHOD_SRAYLEIGH_ICDF, VSL_METHOD_DRAYLEIGH_ICDF, VSL_METHOD_SRAYLEIGH_ICDF_ACCURATE, VSL_METHOD_DRAYLEIGH_ICDF_ACCURATE	VSL_RNG_METHOD_RAYLEIGH_ICDF, VSL_RNG_METHOD_RAYLEIGH_ICDF_ACCURATE
vRngLognormal	VSL_METHOD_SLOGNORMAL_BOXMULLER2, VSL_METHOD_DLOGNORMAL_BOXMULLER2, VSL_METHOD_SLOGNORMAL_BOXMULLER2_ACCURATE, VSL_METHOD_DLOGNORMAL_BOXMULLER2_ACCURATE	VSL_RNG_METHOD_LOGNORMAL_BOXMULLER2, VSL_RNG_METHOD_LOGNORMAL_BOXMULLER2_ACCURATE
	VSL_METHOD_SLOGNORMAL_ICDF, VSL_METHOD_DLOGNORMAL_ICDF, VSL_METHOD_SLOGNORMAL_ICDF_ACCURATE, VSL_METHOD_DLOGNORMAL_ICDF_ACCURATE	VSL_RNG_METHOD_LOGNORMAL_ICDF, VSL_RNG_METHOD_LOGNORMAL_ICDF_ACCURATE
vRngGumbel	VSL_METHOD_SGUMBEL_ICDF, VSL_METHOD_DGUMBEL_ICDF	VSL_RNG_METHOD_GUMBEL_ICDF
vRngGamma	VSL_METHOD_SGAMMA_GNORM, VSL_METHOD_DGAMMA_GNORM, VSL_METHOD_SGAMMA_GNORM_ACCURATE, VSL_METHOD_DGAMMA_GNORM_ACCURATE	VSL_RNG_METHOD_GAMMA_GNORM, VSL_RNG_METHOD_GAMMA_GNORM_ACCURATE
vRngBeta	VSL_METHOD_SBETA_CJA, VSL_METHOD_DBETA_CJA, VSL_METHOD_SBETA_CJA_ACCURATE, VSL_METHOD_DBETA_CJA_ACCURATE	VSL_RNG_METHOD_BETA_CJA, VSL_RNG_METHOD_BETA_CJA_ACCURATE

Method Names for Discrete Distribution Generators

RNG	Legacy Method Name	New Method Name
vRngUniform	VSL_METHOD_IUNIFORM_STD	VSL_RNG_METHOD_UNIFORM_STD
vRngUniformBits	VSL_METHOD_IUNIFORMBITS_STD	VSL_RNG_METHOD_UNIFORMBITS_STD
vRngBernoulli	VSL_METHOD_IBERNOULLI_ICDF	VSL_RNG_METHOD_BERNOULLI_ICDF
vRngGeometric	VSL_METHOD_IGEOMETRIC_ICDF	VSL_RNG_METHOD_GEOMETRIC_ICDF
vRngBinomial	VSL_METHOD_IBINOMIAL_BTPE	VSL_RNG_METHOD_BINOMIAL_BTPE
vRngHypergeometric	VSL_METHOD_IHYPERGEOMETRIC_H2PE	VSL_RNG_METHOD_HYPERGEOMETRIC_H2PE
vRngPoisson	VSL_METHOD_IPOISSON_PTPE, VSL_METHOD_IPOISSON_POISNORM	VSL_RNG_METHOD_POISSON_PTPE, VSL_RNG_METHOD_POISSON_POISNORM
vRngPoissonV	VSL_METHOD_IPOISSONV_POISNORM	VSL_RNG_METHOD_POISSONV_POISNORM
vRngNegBinomial	VSL_METHOD_INEGBINOMIAL_NBAR	VSL_RNG_METHOD_NEGBINOMIAL_NBAR

Continuous Distributions

This section describes routines for generating random numbers with continuous distribution.

`vRngUniform` *Continuous Distribution Generators*

Generates random numbers with uniform distribution.

Syntax

```
status = vsrnguniform( method, stream, n, r, a, b )
status = vdrnguniform( method, stream, n, r, a, b )
```

Include Files

- `mkl.fi`, `mkl_vsl.f90`

Description

The `vRngUniform` function generates random numbers uniformly distributed over the interval `[a, b)`, where `a, b` are the left and right bounds of the interval, respectively, and `a, b∈R ; a < b`.

The probability density function is given by:

$$f_{a,b}(x) = \begin{cases} \dfrac{1}{b-a}, & x \in [a,b) \\ 0, & x \notin [a,b) \end{cases}, \quad -\infty < x < +\infty$$

The cumulative distribution function is as follows:

$$f_{a,b}(x) = \begin{cases} 0, & x < a \\ \dfrac{x-a}{b-a}, & a \le x < b \\ 1, & x \ge b \end{cases}, \quad -\infty < x < +\infty .$$

Input Parameters

Name	Type	Description

method	INTEGER, INTENT(IN)	Generation method; the specific values are as follows:
		`VSL_RNG_METHOD_UNIFORM_STD`
		`VSL_RNG_METHOD_UNIFORM_STD_ACCURATE`
		Standard method.

Name	Type	Description
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of random values to be generated.
a	DOUBLE PRECISION for vdrnguniform REAL (KIND=4), INTENT(IN) for vsrnguniform REAL (KIND=8), INTENT(IN) for vdrnguniform	Left bound a.
b	DOUBLE PRECISION for vdrnguniform REAL (KIND=4), INTENT(IN) for vsrnguniform REAL (KIND=8), INTENT(IN) for vdrnguniform	Right bound b.

Output Parameters

Name	Type	Description
r	DOUBLE PRECISION for vdrnguniform REAL (KIND=4), INTENT(OUT) for vsrnguniform REAL (KIND=8), INTENT(OUT) for vdrnguniform	Vector of n random numbers uniformly distributed over the interval [*a*,*b*)

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax .
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngGaussian
Generates normally distributed random numbers.

Syntax

status = vsrnggaussian(*method*, *stream*, *n*, *r*, *a*, *sigma*)

status = vdrnggaussian(*method*, *stream*, *n*, *r*, *a*, *sigma*)

Include Files

- mkl.fi, mkl_vsl.f90

Description

The vRngGaussian function generates random numbers with normal (Gaussian) distribution with mean value a and standard deviation σ, where

$a, \sigma \in R ; \sigma > 0.$

The probability density function is given by:

$$f_{a,\sigma}(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-a)^2}{2\sigma^2}\right), \quad -\infty < x < +\infty .$$

The cumulative distribution function is as follows:

$$F_{a,\sigma}(x) = \int_{-\infty}^{x} \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(y-a)^2}{2\sigma^2}\right) dy, \quad -\infty < x < +\infty .$$

The cumulative distribution function $F_{a,\sigma}(x)$ can be expressed in terms of standard normal distribution $\Phi(x)$ as

$F_{a,\sigma}(x) = \Phi((x - a)/\sigma)$

Input Parameters

Name	Type	Description

method	INTEGER, INTENT(IN)	Generation method. The specific values are as follows:
		`VSL_RNG_METHOD_GAUSSIAN_BOXMULLER`
		`VSL_RNG_METHOD_GAUSSIAN_BOXMULLER2`
		`VSL_RNG_METHOD_GAUSSIAN_ICDF`
		See brief description of the methods `BOXMULLER`, `BOXMULLER2`, and `ICDF` in Table "Values of <*method*> in *method* parameter"

stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure
n	INTEGER, INTENT(IN)	Number of random values to be generated.
a	DOUBLE PRECISION for vdrnggaussian REAL (KIND=4), INTENT(IN) for vsrnggaussian REAL (KIND=8), INTENT(IN) for vdrnggaussian	Mean value a.
sigma	DOUBLE PRECISION for vdrnggaussian REAL (KIND=4), INTENT(IN) for vsrnggaussian REAL (KIND=8), INTENT(IN) for vdrnggaussian	Standard deviation σ.

Output Parameters

Name	Type	Description
r	DOUBLE PRECISION for vdrnggaussian REAL (KIND=4), INTENT(OUT) for vsrnggaussian	Vector of `n` normally distributed random numbers.

Name	Type	Description
	REAL (KIND=8), INTENT(OUT) for vdrnggaussian	

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngGaussianMV
Generates random numbers from multivariate normal distribution.

Syntax

status = vsrnggaussianmv(*method*, *stream*, *n*, *r*, *dimen*, *mstorage*, *a*, *t*)

status = vdrnggaussianmv(*method*, *stream*, *n*, *r*, *dimen*, *mstorage*, *a*, *t*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method. The specific values are as follows: VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER2 VSL_RNG_METHOD_GAUSSIANMV_ICDF See brief description of the methods BOXMULLER, BOXMULLER2, and ICDF in Table "Values of <*method*> in *method* parameter"

Name	Type	Description
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of *d*-dimensional vectors to be generated
dimen	INTEGER, INTENT(IN)	Dimension d ($d \geq 1$) of output random vectors
mstorage	INTEGER, INTENT(IN)	Matrix storage scheme for upper triangular matrix T^T. The routine supports three matrix storage schemes: • VSL_MATRIX_STORAGE_FULL— all d x d elements of the matrix T^T are passed, however, only the upper triangle part is actually used in the routine. • VSL_MATRIX_STORAGE_PACKED— upper triangle elements of T^T are packed by rows into a one-dimensional array. • VSL_MATRIX_STORAGE_DIAGONAL— only diagonal elements of T^T are passed.
a	DOUBLE PRECISION for vdrnggaussianmv REAL(KIND=4), INTENT(IN) for vsrnggaussianmv REAL(KIND=8), INTENT(IN) for vdrnggaussianmv	Mean vector *a* of dimension *d*
t	DOUBLE PRECISION for vdrnggaussianmv REAL(KIND=4), INTENT(IN) for vsrnggaussianmv REAL(KIND=8), INTENT(IN) for vdrnggaussianmv	Elements of the upper triangular matrix passed according to the matrix T^T storage scheme *mstorage*.

Output Parameters

Name	Type	Description
r	DOUBLE PRECISION for vdrnggaussianmv REAL(KIND=4), INTENT(OUT) for vsrnggaussianmv REAL(KIND=8), INTENT(OUT) for vdrnggaussianmv	Array of *n* random vectors of dimension *dimen*

Description

The vRngGaussianMV function generates random numbers with *d*-variate normal (Gaussian) distribution with mean value a and variance-covariance matrix *C*, where $a \in R^d$; C is a $d \times d$ symmetric positive-definite matrix.

The probability density function is given by:

$$f_{a,C}(x) = \frac{1}{\sqrt{\det(2\pi C)}} \exp\left(-1/2(x-a)^T C^{-1}(x-a)\right),$$

where $x \in R^d$.

Matrix *C* can be represented as $C = TT^T$, where *T* is a lower triangular matrix - Cholesky factor of *C*.

Instead of variance-covariance matrix *C* the generation routines require Cholesky factor of *C* in input. To compute Cholesky factor of matrix *C*, the user may call Intel® oneAPI Math Kernel Library (oneMKL) LAPACK routines for matrix factorization: `?potrf` or `?pptrf` for `v?RngGaussianMV`/`v?rnggaussianmv` routines (`?` means either `s` or `d` for single and double precision respectively). See Application Notes for more details.

Product and Performance Information

Application Notes

Since matrices are stored in Fortran by columns, while in C they are stored by rows, the usage of Intel® oneAPI Math Kernel Library (oneMKL) factorization routines (assuming Fortran matrices storage) in combination with multivariate normal RNG (assuming C matrix storage) is slightly different in C and Fortran. The following tables help in using these routines in C and Fortran. For further information please refer to the appropriate VS example file.

Using Cholesky Factorization Routines in Fortran

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
`VSL_MATRIX_STORAGE_FULL`	*C* in Fortran two-dimensional array	`spotrf` for `vsrnggaussianmv` `dpotrf` for `vdrnggaussianmv`	'U'	Upper triangle of T^T. Lower triangle is not used.
`VSL_MATRIX_STORAGE_PACKED`	Lower triangle of *C* packed by columns into one-dimensional array	`spptrf` for `vsrnggaussianmv` `dpptrf` for `vdrnggaussianmv`	'L'	Upper triangle of T^T packed by rows into a one-dimensional array.

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	*stream* is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*stream* is not a valid random stream.

VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngExponential
Generates exponentially distributed random numbers.

Syntax

status = vsrngexponential(*method*, *stream*, *n*, *r*, *a*, *beta*)

status = vdrngexponential(*method*, *stream*, *n*, *r*, *a*, *beta*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method. The specific values are as follows: VSL_RNG_METHOD_EXPONENTIAL_ICDF VSL_RNG_METHOD_EXPONENTIAL_ICDF_ACCURATE Inverse cumulative distribution function method
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of random values to be generated
a	DOUBLE PRECISION for vdrngexponential REAL(KIND=4), INTENT(IN) for vsrngexponential REAL(KIND=8), INTENT(IN) for vdrngexponential	Displacement *a*
beta	DOUBLE PRECISION for vdrngexponential	Scalefactor β.

Name	Type	Description
	`REAL(KIND=4), INTENT(IN)` for `vsrngexponential` `REAL(KIND=8), INTENT(IN)` for `vdrngexponential`	

Output Parameters

Name	Type	Description

r	`DOUBLE PRECISION` for `vdrngexponential`
	`REAL(KIND=4), INTENT(OUT)` for `vsrngexponential`
	`REAL(KIND=8), INTENT(OUT)` for `vdrngexponential`
		Vector of *n* exponentially distributed random numbers

Description

The `vRngExponential` function generates random numbers with exponential distribution that has displacement `a` and scalefactor β, where $a,\ \beta \in R\ ;\ \beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{\beta} \exp\left((-(x-a)) / \beta \right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp\left((-(x-a)) / \beta \right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Notice revision #20201201

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	*`stream`* is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*stream* is not a valid random stream.
`VSL_RNG_ERROR_BAD_UPDATE`	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, `< 0` or `> nmax`.

VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngLaplace
Generates random numbers with Laplace distribution.

Syntax

status = vsrnglaplace(*method*, *stream*, *n*, *r*, *a*, *beta*)

status = vdrnglaplace(*method*, *stream*, *n*, *r*, *a*, *beta*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method. The specific values are as follows: VSL_RNG_METHOD_LAPLACE_ICDF Inverse cumulative distribution function method
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of random values to be generated
a	DOUBLE PRECISION for vdrnglaplace REAL(KIND=4), INTENT(IN) for vsrnglaplace REAL(KIND=8), INTENT(IN) for vdrnglaplace	Mean value *a*
beta	DOUBLE PRECISION for vdrnglaplace REAL(KIND=4), INTENT(IN) for vsrnglaplace REAL(KIND=8), INTENT(IN) for vdrnglaplace	Scalefactor β.

Output Parameters

Name	Type	Description
r	DOUBLE PRECISION for vdrnglaplace REAL(KIND=4), INTENT(OUT) for vsrnglaplace REAL(KIND=8), INTENT(OUT) for vdrnglaplace	Vector of *n* Laplace distributed random numbers

Description

The vRngLaplace function generates random numbers with Laplace distribution with mean value (or average) *a* and scalefactor β, where $a,\ \beta \in R\ ;\ \beta > 0$. The scalefactor value determines the standard deviation as

$$\sigma = \beta\sqrt{2}$$

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\sqrt{2}\beta} \exp\left(-\frac{|x-a|}{\beta}\right), -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{2}\exp\left(-\frac{|x-a|}{\beta}\right), & x \geq a \\ 1 - \frac{1}{2}\exp\left(-\frac{|x-a|}{\beta}\right), & x < a \end{cases}, -\infty < x < +\infty.$$

Product and Performance Information

alpha	DOUBLE PRECISION for vdrngweibull REAL(KIND=4), INTENT(IN) for vsrngweibull REAL(KIND=8), INTENT(IN) for vdrngweibull	Shape α.
a	DOUBLE PRECISION for vdrngweibull REAL(KIND=4), INTENT(IN) for vsrngweibull REAL(KIND=8), INTENT(IN) for vdrngweibull	Displacement *a*

Name	Type	Description

beta	`DOUBLE PRECISION` for `vdrngweibull`
	`REAL(KIND=4), INTENT(IN)` for `vsrngweibull`
	`REAL(KIND=8), INTENT(IN)` for `vdrngweibull`
		Scalefactor β.

Output Parameters

Name	Type	Description

r	`DOUBLE PRECISION` for `vdrngweibull`
	`REAL(KIND=4), INTENT(OUT)` for `vsrngweibull`
	`REAL(KIND=8), INTENT(OUT)` for `vdrngweibull`
		Vector of *n* Weibull distributed random numbers

Description

The `vRngWeibull` function generates Weibull distributed random numbers with displacement *a*, scalefactor β, and shape α, where α, β, *a*∈*R* ; α > 0, β > 0.

The probability density function is given by:

$$f_{a,\alpha,\beta}(x) = \begin{cases} \frac{\alpha}{\beta^{\alpha}}(x-a)^{\alpha-1}\exp\left(-\left(\frac{x-a}{\beta}\right)^{\alpha}\right), & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\alpha,\beta}(x) = \begin{cases} 1-\exp\left(-\left(\frac{x-a}{\beta}\right)^{\alpha}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

r	`DOUBLE PRECISION` for `vdrngrayleigh`
	`REAL(KIND=4), INTENT(OUT)` for `vsrngrayleigh`
	`REAL(KIND=8), INTENT(OUT)` for `vdrngrayleigh`
		Vector of *n* Rayleigh distributed random numbers

Description

The `vRngRayleigh` function generates Rayleigh distributed random numbers with displacement *a* and scalefactor β, where $a, \beta \in R ; \beta > 0$.

The Rayleigh distribution is a special case of the `Weibull` distribution, where the shape parameter $\alpha = 2$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{2(x-a)}{\beta^2} \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

		Standard deviation σ of the subject normal distribution

b	`DOUBLE PRECISION` for `vdrnglognormal`
	`REAL(KIND=4), INTENT(IN)` for `vsrnglognormal`
	`REAL(KIND=8), INTENT(IN)` for `vdrnglognormal`
		Displacement *b*

beta	`DOUBLE PRECISION` for `vdrnglognormal`
	`REAL(KIND=4), INTENT(IN)` for `vsrnglognormal`
	`REAL(KIND=8), INTENT(IN)` for `vdrnglognormal`
		Scalefactor β.

Output Parameters

Name	Type	Description

r	`DOUBLE PRECISION` for `vdrnglognormal`
	`REAL(KIND=4), INTENT(OUT)` for `vsrnglognormal`
	`REAL(KIND=8), INTENT(OUT)` for `vdrnglognormal`
		Vector of *n* lognormally distributed random numbers

Description

The `vRngLognormal` function generates lognormally distributed random numbers with average of distribution *a* and standard deviation σ of subject normal distribution, displacement *b*, and scalefactor β, where a, σ, b, $\beta \in R$; $\sigma > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{a,\sigma,b,\beta}(x) = \begin{cases} \dfrac{1}{\sigma(x-b)\sqrt{2\pi}} \exp\left(-\dfrac{\left[\ln((x-b)/\beta) - a\right]^2}{2\sigma^2}\right), & x > b \\ 0, & x \le b \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\sigma,b,\beta}(x) = \begin{cases} \Phi(\ (\ln(\ (x - b) / \beta) - a)/\sigma)\ , & x > b \\ 0, & x \le b \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngGumbel
Generates Gumbel distributed random values.

Syntax

status = vsrnggumbel(*method*, *stream*, *n*, *r*, *a*, *beta*)

status = vdrnggumbel(*method*, *stream*, *n*, *r*, *a*, *beta*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method. The specific values are as follows: VSL_RNG_METHOD_GUMBEL_ICDF Inverse cumulative distribution function method

Name	Type	Description
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure
n	INTEGER, INTENT(IN)	Number of random values to be generated
a	DOUBLE PRECISION for vdrnggumbel REAL(KIND=4), INTENT(IN) for vsrnggumbel REAL(KIND=8), INTENT(IN) for vdrnggumbel	Displacement a.
beta	DOUBLE PRECISION for vdrnggumbel REAL(KIND=4), INTENT(IN) for vsrnggumbel REAL(KIND=8), INTENT(IN) for vdrnggumbel	Scalefactor β.

Output Parameters

Name	Type	Description
r	DOUBLE PRECISION for vdrnggumbel REAL(KIND=4), INTENT(OUT) for vsrnggumbel REAL(KIND=8), INTENT(OUT) for vdrnggumbel	Vector of *n* random numbers with Gumbel distribution

Description

The vRngGumbel function generates Gumbel distributed random numbers with displacement a and scalefactor β, where a, β∈*R* ; β > 0.

The probability density function is given by:

$$f_{a,\beta}(x) = \left\{\frac{1}{\beta}\exp\left(\frac{x-a}{\beta}\right)\exp(-\exp((x-a)/\beta)), -\infty < x < +\infty\right.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = 1 - \exp(-\exp((x-a)/\beta)), -\infty < x < +\infty$$

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngGamma
Generates gamma distributed random values.

Syntax

status = vsrnggamma(*method*, *stream*, *n*, *r*, *alpha*, *a*, *beta*)

status = vdrnggamma(*method*, *stream*, *n*, *r*, *alpha*, *a*, *beta*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method. The specific values are as follows: VSL_RNG_METHOD_GAMMA_GNORM VSL_RNG_METHOD_GAMMA_GNORM_ACCURATE Acceptance/rejection method using random numbers with Gaussian distribution. See brief description of the method GNORM in Table "Values of <*method*> in *method* parameter"
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure
n	INTEGER, INTENT(IN)	Number of random values to be generated

Name	Type	Description

alpha	`DOUBLE PRECISION` for `vdrnggamma`
	`REAL(KIND=4), INTENT(IN)` for `vsrnggamma`
	`REAL(KIND=8), INTENT(IN)` for `vdrnggamma`
		Shape α.

a	`DOUBLE PRECISION` for `vdrnggamma`
	`REAL(KIND=4), INTENT(IN)` for `vsrnggamma`
	`REAL(KIND=8), INTENT(IN)` for `vdrnggamma`
		Displacement *a*.

beta	`DOUBLE PRECISION` for `vdrnggamma`
	`REAL(KIND=4), INTENT(IN)` for `vsrnggamma`
	`REAL(KIND=8), INTENT(IN)` for `vdrnggamma`
		Scalefactor β.

Output Parameters

Name	Type	Description

r	`DOUBLE PRECISION` for `vdrnggamma`
	`REAL(KIND=4), INTENT(OUT)` for `vsrnggamma`
	`REAL(KIND=8), INTENT(OUT)` for `vdrnggamma`
		Vector of *n* random numbers with gamma distribution

Description

The `vRngGamma` function generates random numbers with gamma distribution that has shape parameter α, displacement *a*, and scale parameter β, where α, β, and $a \in R$; $\alpha > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{\alpha,a,\beta}(x) = \begin{cases} \frac{1}{\Gamma(\alpha)\beta^{\alpha}}(x-a)^{\alpha-1}e^{-(x-a)/\beta}, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

where Γ(α) is the complete gamma function.

The cumulative distribution function is as follows:

$$F_{\alpha,a,\beta}(x) = \begin{cases} \int_a^x \frac{1}{\Gamma(\alpha)\beta^\alpha}(y-a)^{\alpha-1}e^{-(y-a)/\beta}dy, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngBeta
Generates beta distributed random values.

Syntax

status = vsrngbeta(*method*, *stream*, *n*, *r*, *p*, *q*, *a*, *beta*)

status = vdrngbeta(*method*, *stream*, *n*, *r*, *p*, *q*, *a*, *beta*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method. The specific values are as follows: VSL_RNG_METHOD_BETA_CJA VSL_RNG_METHOD_BETA_CJA_ACCURATE See brief description of the method CJA in Table "Values of <method> in *method* parameter"
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure
n	INTEGER, INTENT(IN)	Number of random values to be generated
p	DOUBLE PRECISION for vdrngbeta REAL(KIND=4), INTENT(IN) for vsrngbeta REAL(KIND=8), INTENT(IN) for vdrngbeta	Shape *p*
q	DOUBLE PRECISION for vdrngbeta REAL(KIND=4), INTENT(IN) for vsrngbeta REAL(KIND=8), INTENT(IN) for vdrngbeta	Shape *q*
a	DOUBLE PRECISION for vdrngbeta REAL(KIND=4), INTENT(IN) for vsrngbeta REAL(KIND=8), INTENT(IN) for vdrngbeta	Displacement*a*.
beta	DOUBLE PRECISION for vdrngbeta REAL(KIND=4), INTENT(IN) for vsrngbeta REAL(KIND=8), INTENT(IN) for vdrngbeta	Scalefactor β.

Output Parameters

Name	Type	Description
r	DOUBLE PRECISION for vdrngbeta	Vector of *n* random numbers with beta distribution

Name	Type	Description
	`REAL(KIND=4), INTENT(OUT)` for `vsrngbeta` `REAL(KIND=8), INTENT(OUT)` for `vdrngbeta`	

Description

The `vRngBeta` function generates random numbers with beta distribution that has shape parameters `p` and *q*, displacement *a*, and scale parameter β, where *p*, *q*, *a*, and β∈R ; $p > 0$, $q > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{p,q,a,\beta}(x) = \begin{cases} \frac{1}{B(p,q)\beta^{p+q-1}}(x-a)^{p-1}(\beta+a-x)^{q-1}, & a \le x < a+\beta \\ 0, & x < a, x \ge a+\beta \end{cases}, -\infty < x <$$

where $B(p, q)$ is the complete beta function.

The cumulative distribution function is as follows:

$$F_{p,q,a,\beta}(x) = \begin{cases} 0, & x < a \\ \int_a^x \frac{1}{B(p,q)\beta^{p+q-1}}(y-a)^{p-1}(\beta+a-y)^{q-1}dy, & a \le x < a+\beta \\ 1, & x \ge a+\beta \end{cases}, -\infty < x$$

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	*`stream`* is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*stream* is not a valid random stream.
`VSL_RNG_ERROR_BAD_UPDATE`	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, `< 0` or `> nmax`.
`VSL_RNG_ERROR_NO_NUMBERS`	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
`VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED`	Period of the generator has been exceeded.

VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngChiSquare
Generates chi-square distributed random values.

Syntax

status = vsrngchisquare(*method*, *stream*, *n*, *r*, *v*)

status = vdrngchisquare(*method*, *stream*, *n*, *r*, *v*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method. The specific value is: VSL_RNG_METHOD_CHISQUARE_CHI2GAMMA For a description of VSL_RNG_METHOD_CHISQUARE_CHI2GAMMA, see Random Number Generators Naming Conventions.
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure
n	INTEGER, INTENT(IN)	Number of random values to be generated
v	INTEGER, INTENT(IN)	Degrees of freedom

Output Parameters

Name	Type	Description
r	REAL(KIND=4), INTENT(OUT) for vsrngchisquare REAL(KIND=8), INTENT(OUT) for vdrngchisquare	Vector of *n* random numbers with chi-square distribution

Description

The vRngChiSquare function generates random numbers with chi-square distribution and *v* degrees of freedom, $v \in N$, $v > 0$.

The probability density function is:

$$f_v(x) = \begin{cases} \frac{x^{\frac{v-2}{2}} e^{-\frac{x}{2}}}{2^{v/2}\Gamma\left(\frac{v}{2}\right)}, & x \geq 0 \\ 0, & x < 0 \end{cases}$$

The cumulative distribution function is:

$$F_v(x) = \begin{cases} \int_0^x \frac{y^{\frac{v-2}{2}} e^{-\frac{y}{2}}}{2^{v/2}\Gamma\left(\frac{v}{2}\right)} dy, & x \geq 0 \\ 0, & x < 0 \end{cases}$$

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	*`stream`* is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*stream* is not a valid random stream.
`VSL_RNG_ERROR_BAD_UPDATE`	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, `< 0` or `> nmax`.
`VSL_RNG_ERROR_NO_NUMBERS`	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
`VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED`	Period of the generator has been exceeded.
`VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED`	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
`VSL_RNG_ERROR_ARS5_NOT_SUPPORTED`	ARS-5 random number generator is not supported on the CPU running the application.

Discrete Distributions

This section describes routines for generating random numbers with discrete distribution.

`vRngUniform` *Discrete Distribution Generators*

Generates random numbers uniformly distributed over the interval `[a, b)`.

Syntax

```
status = virnguniform( method, stream, n, r, a, b )
```

Include Files

- `mkl.fi, mkl_vsl.f90`

Input Parameters

Name	Type	Description
`method`	`INTEGER, INTENT(IN)`	Generation method; the specific value is as follows: `VSL_RNG_METHOD_UNIFORM_STD`

Name	Type	Description
		Standard method. Currently there is only one method for this distribution generator.
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of random values to be generated
a	INTEGER(KIND=4), INTENT(IN)	Left interval bound a
b	INTEGER(KIND=4), INTENT(IN)	Right interval bound b

Output Parameters

Name	Type	Description
r	INTEGER(KIND=4), INTENT(OUT)	Vector of *n* random numbers uniformly distributed over the interval [*a*,*b*)

Description

The vRngUniform function generates random numbers uniformly distributed over the interval [*a*, *b*), where *a*, *b* are the left and right bounds of the interval respectively, and *a*, *b*∈*Z*; *a* < *b*.

The probability distribution is given by:

$$P(X = k) = \frac{1}{b - a}, k \in \{a, a + 1, \ldots, b - 1\}.$$

The cumulative distribution function is as follows:

$$F_{a,b}(x) = \begin{cases} 0, & x < a \\ \dfrac{\lfloor x - a + 1 \rfloor}{b - a}, & a \le x < b, x \in R. \\ 1, & x \ge b \end{cases}$$

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.

VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngUniformBits
Generates bits of underlying BRNG integer recurrence.

Syntax

status = virnguniformbits(*method*, *stream*, *n*, *r*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method; the specific value is VSL_RNG_METHOD_UNIFORMBITS_STD
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of random values to be generated

Output Parameters

Name	Type	Description
r	INTEGER(KIND=4), INTENT(OUT)	Vector of *n* random integer numbers. If the *stream* was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of *r* respectively. The number of bytes occupied by each integer is contained in the field *wordsize* of the structure VSL_BRNG_PROPERTIES. The total number of bits that are actually used to store the value are contained in the field *nbits* of the same structure. See Advanced Service Routines for a more detailed discussion of VSLBRngProperties.

Description

The `vRngUniformBits` function generates integer random values with uniform bit distribution. The generators of uniformly distributed numbers can be represented as recurrence relations over integer values in modular arithmetic. Apparently, each integer can be treated as a vector of several bits. In a truly random generator, these bits are random, while in pseudorandom generators this randomness can be violated. For example, a well known drawback of linear congruential generators is that lower bits are less random than higher bits (for example, see [Knuth81]). For this reason, care should be taken when using this function. Typically, in a 32-bit *LCG* only 24 higher bits of an integer value can be considered random. See VS Notes for details.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	*`stream`* is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*`stream`* is not a valid random stream.
`VSL_RNG_ERROR_BAD_UPDATE`	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, `< 0` or `> nmax`.
`VSL_RNG_ERROR_NO_NUMBERS`	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
`VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED`	Period of the generator has been exceeded.
`VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED`	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
`VSL_RNG_ERROR_ARS5_NOT_SUPPORTED`	ARS-5 random number generator is not supported on the CPU running the application.

vRngUniformBits32
Generates uniformly distributed bits in 32-bit chunks.

Syntax

```
status = virnguniformbits32( method, stream, n, r )
```

Include Files

- `mkl.fi, mkl_vsl.f90`

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method; the specific value is VSL_RNG_METHOD_UNIFORMBITS32_STD
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of random values to be generated

Output Parameters

Name	Type	Description
r	INTEGER (KIND=4), INTENT(OUT)	Vector of *n* 32-bit random integer numbers with uniform bit distribution.

Description

The vRngUniformBits32 function generates uniformly distributed bits in 32-bit chunks. Unlike vRngUniformBits, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, vRngUniformBits32 is designed to ensure each bit in the 32-bit chunk is uniformly distributed. See VS Notes for details.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngUniformBits64
Generates uniformly distributed bits in 64-bit chunks.

Syntax

```
status = virnguniformbits64( method, stream, n, r )
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method; the specific value is VSL_RNG_METHOD_UNIFORMBITS64_STD
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of random values to be generated

Output Parameters

Name	Type	Description
r	INTEGER (KIND=8), INTENT(OUT)	Vector of *n* 64-bit random integer numbers with uniform bit distribution.

Description

The vRngUniformBits64 function generates uniformly distributed bits in 64-bit chunks. Unlike vRngUniformBits, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, vRngUniformBits64 is designed to ensure each bit in the 64-bit chunk is uniformly distributed. See VS Notes for details.

Notice revision #20201201

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngBernoulli
Generates Bernoulli distributed random values.

Syntax

```
status = virngbernoulli( method, stream, n, r, p )
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method. The specific value is as follows: VSL_RNG_METHOD_BERNOULLI_ICDF Inverse cumulative distribution function method.
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of random values to be generated
p	REAL(KIND=8), INTENT(IN)	Success probability *p* of a trial

Output Parameters

Name	Type	Description
r	INTEGER(KIND=4), INTENT(OUT)	Vector of *n* Bernoulli distributed random values

Description

The vRngBernoulli function generates Bernoulli distributed random numbers with probability *p* of a single trial success, where

$p \in R;\ 0 \le p \le 1.$

A variate is called Bernoulli distributed, if after a trial it is equal to 1 with probability of success *p*, and to 0 with probability 1 - *p*.

The probability distribution is given by:

$P(X = 1) = p$

$P(X = 0) = 1 - p$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - p, & 0 \le x < 1, x \in R. \\ 1, & x \ge 1 \end{cases}$$

Product and Performance Information

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngGeometric
Generates geometrically distributed random values.

Syntax

```
status = virnggeometric( method, stream, n, r, p )
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method. The specific value is as follows: VSL_RNG_METHOD_GEOMETRIC_ICDF Inverse cumulative distribution function method.
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of random values to be generated
p	REAL(KIND=8), INTENT(IN)	Success probability *p* of a trial

Output Parameters

Name	Type	Description
r	INTEGER(KIND=4), INTENT(OUT)	Vector of *n* geometrically distributed random values

Description

The vRngGeometric function generates geometrically distributed random numbers with probability *p* of a single trial success, where *p*∈*R*; 0 < *p* < 1.

A geometrically distributed variate represents the number of independent Bernoulli trials preceding the first success. The probability of a single Bernoulli trial success is *p*.

The probability distribution is given by:

$P(X = k) = p \cdot (1 - p)^k$, $k \in \{0,1,2, \ldots\}$.

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - (1 - p)^{\lfloor x+1 \rfloor}, & 0 \geq x \end{cases} \qquad x \in R.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngBinomial
Generates binomially distributed random numbers.

Syntax

`status = virngbinomial( method, stream, n, r, ntrial, p )`

Include Files

- `mkl.fi, mkl_vsl.f90`

Input Parameters

Name	Type	Description
method	`INTEGER, INTENT(IN)`	Generation method. The specific value is as follows: `VSL_RNG_METHOD_BINOMIAL_BTPE` See brief description of the `BTPE` method in Table "Values of <*method*> in *method* parameter".
stream	`TYPE (VSL_STREAM_STATE), INTENT(IN)`	Descriptor of the stream state structure.
n	`INTEGER, INTENT(IN)`	Number of random values to be generated
ntrial	`INTEGER(KIND=4), INTENT(IN)`	Number of independent trials `m`
p	`REAL(KIND=8), INTENT(IN)`	Success probability *p* of a single trial

Output Parameters

Name	Type	Description
r	`INTEGER(KIND=4), INTENT(OUT)`	Vector of *n* binomially distributed random values

Description

The `vRngBinomial` function generates binomially distributed random numbers with number of independent Bernoulli trials *m*, and with probability *p* of a single trial success, where $p \in R;\ 0 \le p \le 1,\ m \in N$.

A binomially distributed variate represents the number of successes in *m* independent Bernoulli trials with probability of a single trial success *p*.

The probability distribution is given by:

$$P(X = k) = C_m^k p^k (1 - p)^{m-k}, k \in \{0, 1, \ldots, m\}.$$

The cumulative distribution function is as follows:

$$F_{m,p}(x) = \begin{cases} 0, & x < 0 \\ \sum_{k=0}^{\lfloor x \rfloor} C_m^k p^k (1-p)^{m-k}, & 0 \le x < m, x \in R \\ 1, & x \ge m \end{cases}$$

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngHypergeometric
Generates hypergeometrically distributed random values.

Syntax

status = virnghypergeometric(*method*, *stream*, *n*, *r*, *l*, *s*, *m*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method. The specific value is as follows: `VSL_RNG_METHOD_HYPERGEOMETRIC_H2PE` See brief description of the `H2PE` method in Table "Values of <*method*> in *method* parameter"
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of random values to be generated
l	INTEGER(KIND=4), INTENT(IN)	Lot size `l`
s	INTEGER(KIND=4), INTENT(IN)	Size of sampling without replacement `s`
m	INTEGER(KIND=4), INTENT(IN)	Number of marked elements `m`

Output Parameters

Name	Type	Description
r	INTEGER(KIND=4), INTENT(OUT)	Vector of *n* hypergeometrically distributed random values

Description

The `vRngHypergeometric` function generates hypergeometrically distributed random values with lot size *l*, size of sampling *s*, and number of marked elements in the lot *m*, where $l, m, s \in N \cup \{0\}; l \geq \max(s, m)$.

Consider a lot of *l* elements comprising *m* "marked" and *l*-*m* "unmarked" elements. A trial sampling without replacement of exactly *s* elements from this lot helps to define the hypergeometric distribution, which is the probability that the group of *s* elements contains exactly *k* marked elements.

The probability distribution is given by:)

$$P(X = k) = \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}$$

, $k \in \{\max(0, s + m - l), \ldots, \min(s, m)\}$

The cumulative distribution function is as follows:

$$F_{l,s,m}(x) = \begin{cases} 0, & x < \max(0, s+m-l) \\ \sum_{k=\max(0,s+m-l)}^{\lfloor x \rfloor} \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}, & \max(0, s+m-l) \le x \le \min(s, m) \\ 1, & x > \min(s, m) \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngPoisson
Generates Poisson distributed random values.

Syntax

status = virngpoisson(*method*, *stream*, *n*, *r*, *lambda*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method. The specific values are as follows: VSL_RNG_METHOD_POISSON_PTPE VSL_RNG_METHOD_POISSON_POISNORM

Name	Type	Description
		See brief description of the PTPE and POISNORM methods in Table "Values of <method> in method parameter".
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of random values to be generated
lambda	REAL(KIND=8), INTENT(IN)	Distribution parameter λ.

Output Parameters

Name	Type	Description
r	INTEGER(KIND=4), INTENT(OUT)	Vector of *n* Poisson distributed random values

Description

The vRng"Poisson function generates Poisson distributed random numbers with distribution parameter λ, where λ∈*R*; λ > 0.

The probability distribution is given by:

$$P(X = k) = \frac{\lambda^k e^{-\lambda}}{k!},$$

k∈ {0, 1, 2, ...}.

The cumulative distribution function is as follows:

$$F_\lambda(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda^k e^{-\lambda}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngPoissonV
Generates Poisson distributed random values with varying mean.

Syntax

status = virngpoissonv(*method*, *stream*, *n*, *r*, *lambda*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method. The specific value is as follows: VSL_RNG_METHOD_POISSONV_POISNORM See brief description of the POISNORM method in Table "Values of <*method*> in *method* parameter"
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	Descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of random values to be generated
lambda	REAL(KIND=8), INTENT(IN)	Array of *n* distribution parameters λ_i.

Output Parameters

Name	Type	Description
r	INTEGER(KIND=4), INTENT(OUT)	Vector of *n* Poisson distributed random values

Description

The vRngPoissonV function generates *n* Poisson distributed random numbers $x_i (i = 1, ..., n)$ with distribution parameter λ_i, where $\lambda_i \in R$; $\lambda_i > 0$.

The probability distribution is given by:

$$P(X_i = k) = \frac{\lambda_i^k \exp(-\lambda_i)}{k!}, k \in \{0, 1, 2, \ldots\}.$$

The cumulative distribution function is as follows:

$$F_{\lambda_i}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda_i^k e^{-\lambda_i}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngNegBinomial
Generates random numbers with negative binomial distribution.

Syntax

status = virngnegbinomial(*method*, *stream*, *n*, *r*, *a*, *p*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
method	INTEGER, INTENT(IN)	Generation method. The specific value is: VSL_RNG_METHOD_NEGBINOMIAL_NBAR See brief description of the NBAR method in Table "Values of <*method*> in *method* parameter"
stream	TYPE (VSL_STREAM_STATE), INTENT(IN)	descriptor of the stream state structure.
n	INTEGER, INTENT(IN)	Number of random values to be generated
a	REAL(KIND=8), INTENT(IN)	The first distribution parameter *a*
p	REAL(KIND=8), INTENT(IN)	The second distribution parameter p

Output Parameters

Name	Type	Description
r	INTEGER(KIND=4), INTENT(OUT)	Vector of *n* random values with negative binomial distribution.

Description

The vRngNegBinomial function generates random numbers with negative binomial distribution and distribution parameters *a* and *p*, where *p*, $a \in R$; $0 < p < 1$; $a > 0$.

If the first distribution parameter $a \in N$, this distribution is the same as Pascal distribution. If $a \in N$, the distribution can be interpreted as the expected time of *a*-th success in a sequence of Bernoulli trials, when the probability of success is *p*.

The probability distribution is given by:

$$P(X = k) = C_{a+k-1}^{k} p^{a}(1 - p)^{k}, k \in \{0, 1, 2, \ldots\}.$$

The cumulative distribution function is as follows:

$$F_{a,p}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} C_{a+k-1}^{k} p^{a}(1-p)^{k}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngMultinomial
Generates multinomially distributed random numbers.

Syntax

```
status = virngmultinomial( method, stream, n, r, ntrial, k, p );
```

Include Files

- mkl.fi
- mkl_vsl.f90

Input Parameters

method

INTEGER, INTENT(IN)

Generation method. The specific value is as follows:

VSL_RNG_METHOD_MULTINOMIAL_MULTPOISSON

stream

TYPE (VSL_STREAM_STATE), INTENT(IN)

Pointer to the stream state structure.

n	INTEGER, INTENT(IN) Number of random values to be generated.
ntrial	INTEGER(KIND=4), INTENT(IN) Number of independent trials *m*.
k	INTEGER(KIND=4), INTENT(IN) Number of possible outcomes.
p	REAL(KIND=8), INTENT(IN) Probability vector of k possible outcomes.

Output Parameters

r	INTEGER(KIND=4), INTENT(OUT) Array of *n* random vectors of dimension *k*.

Description

The vRngMultinomial function generates multinomially distributed random numbers with *m* independent trials and *k* possible mutually exclusive outcomes, with corresponding probabilities p_i, where $p_i \in R$; $0 \le p_i \le 1$, $m \in N$, $k \in N$.

The probability distribution is given by:

$$P(X_1 = x_1, \ldots, X_k = x_k) = \frac{m!}{\prod_{i=1}^{k} x_i!} \prod_{i=1}^{k} p_i^{x_i}, \qquad 0 \le x_i \le m, \sum_{i=1}^{k} x_i = m$$

Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

Notice revision #20201201

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error (execution was successful).
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	A callback function for an abstract BRNG returns an invalid number of updated entries in a buffer; that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	A callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	An ARS-5 random number generator is not supported on the CPU running the application.

VSL_DISTR_MULTINOMIAL_BAD_PROBABILITY_ARRAY	Bad multinomial distribution probability array.

Advanced Service Routines

This section describes service routines for obtaining properties of the previously registered basic generators (vslGetBrngProperties). See VS Notes ("Basic Generators" section of VS Structure chapter) for substantiation of the need for several basic generators including user-defined BRNGs.

> **NOTE**
> The vslRegisterBrng function is provided in C for registering a user-defined basic generator, but it is not supported for Fortran. If you need to use a user-defined generator in Fortran, use an abstract basic random generator and abstract stream as described in the VS Notes.

Advanced Service Routine Data Types

The Advanced Service routines refer to a structure defining the properties of the basic generator.

This structure is described in Fortran 90 as follows:

```
TYPE VSL_BRNG_PROPERTIES
    INTEGER streamstatesize
    INTEGER nseeds
    INTEGER includeszero
    INTEGER wordsize
    INTEGER nbits
    INTEGER reserved(8)
END TYPE VSL_BRNG_PROPERTIES
```

The following table provides brief descriptions of the fields engaged in the above structure:

Field Descriptions

Field	Short Description
streamstatesize	The size, in bytes, of the stream state structure for a given basic generator.
nseeds	The number of 32-bit initial conditions (seeds) necessary to initialize the stream state structure for a given basic generator.
includeszero	Flag value indicating whether the generator can produce a random 0.
wordsize	Machine word size, in bytes, used in integer-value computations. Possible values: 4, 8, and 16 for 32, 64, and 128-bit generators, respectively.
nbits	The number of bits required to represent a random value in integer arithmetic. Note that, for instance, 48-bit random values are stored to 64-bit (8 byte) memory locations. In this case, wordsize/WordSize is equal to 8 (number of bytes used to store the random value), while nbits/NBits contains the actual number of bits occupied by the value (in this example, 48).
reserved(8)	Reserved for internal use.

NOTE
Using Advanced Service routines for defining generators is not supported for Fortran, but you can use the Fortran interface to get information about a previously-registered generator using `vslGetBrngProperties`.

vslGetBrngProperties

Returns structure with properties of a given basic generator.

Syntax

```
status = vslgetbrngproperties( brng, properties )
```

Include Files

- `mkl.fi`, `mkl_vsl.f90`

Input Parameters

Name	Type	Description
brng	`INTEGER(KIND=4), INTENT(IN)`	Number (index) of the registered basic generator; used for identification. See specific values in Table "Values of *brng* parameter". Negative values indicate the registration error.

Output Parameters

Name	Type	Description
properties	`TYPE(VSL_BRNG_PROPERTIES), INTENT(OUT)`	Pointer to the structure containing properties of the generator with number *brng*

Description

The `vslGetBrngProperties` function returns a structure with properties of a given basic generator.

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_RNG_ERROR_INVALID_BRNG_INDEX`	BRNG index is invalid.

Convolution and Correlation

Intel® oneAPI Math Kernel Library (oneMKL) VS provides a set of routines intended to perform linear convolution and correlation transformations for single and double precision real and complex data.

For correct definition of implemented operations, see the Mathematical Notation and Definitions.

The current implementation provides:

- Fourier algorithms for one-dimensional single and double precision real and complex data
- Fourier algorithms for multi-dimensional single and double precision real and complex data
- Direct algorithms for one-dimensional single and double precision real and complex data
- Direct algorithms for multi-dimensional single and double precision real and complex data

One-dimensional algorithms cover the following functions from the IBM* ESSL library:

```
SCONF, SCORF
SCOND, SCORD
SDCON, SDCOR
DDCON, DDCOR
SDDCON, SDDCOR.
```

Special wrappers are designed to simulate these ESSL functions. The wrappers are provided as sample sources:

```
${MKL}/examples/vslf/essl/vsl_wrappers
```

Additionally, you can browse the examples demonstrating the calculation of the ESSL functions through the wrappers:

```
${MKL}/examples/vslf/essl
```

The convolution and correlation API provides interfaces for Fortran 90 and C/89 languages. You can use the Fortran 90 interface with programs written in Fortran.

Intel® oneAPI Math Kernel Library (oneMKL) provides the `mkl_vsl.f90` header file. All header files are in the directory

`${MKL}/include`

See more details about the Fortran header in Random Number Generators topic.

The convolution and correlation API is implemented through task objects, or tasks. Task object is a data structure, or descriptor, which holds parameters that determine the specific convolution or correlation operation. Such parameters may be precision, type, and number of dimensions of user data, an identifier of the computation algorithm to be used, shapes of data arrays, and so on.

All the Intel® oneAPI Math Kernel Library (oneMKL) VS convolution and correlation routines process task objects in one way or another: either create a new task descriptor, change the parameter settings, compute mathematical results of the convolution or correlation using the stored parameters, or perform other operations. Accordingly, all routines are split into the following groups:

Task Constructors - routines that create a new task object descriptor and set up most common parameters.

Task Editors - routines that can set or modify some parameter settings in the existing task descriptor.

Task Execution Routines - compute results of the convolution or correlation operation over the actual input data, using the operation parameters held in the task descriptor.

Task Copy - routines used to make several copies of the task descriptor.

Task Destructors - routines that delete task objects and free the memory.

When the task is executed or copied for the first time, a special process runs which is called task commitment. During this process, consistency of task parameters is checked and the required work data are prepared. If the parameters are consistent, the task is tagged as committed successfully. The task remains committed until you edit its parameters. Hence, the task can be executed multiple times after a single commitment process. Since the task commitment process may include costly intermediate calculations such as preparation of Fourier transform of input data, launching the process only once can help speed up overall performance.

Convolution and Correlation Naming Conventions

The names of routines in the convolution and correlation API are written in lowercase (`vslsconvexec`), while the names of Fortran types and constants are written in uppercase. The names are not case-sensitive.

The names of routines have the following structure:

`vsl[`*datatype*`]{conv|corr}<base name>`

where

- `vsl` is a prefix indicating that the routine belongs to Intel® MKL Vector Statistics.
- `[datatype]` is optional. If present, the symbol specifies the type of the input and output data and can be `s` (for single precision real type), `d` (for double precision real type), `c` (for single precision complex type), or `z` (for double precision complex type).
- `Conv` or `Corr` specifies whether the routine refers to convolution or correlation task, respectively.
- `<base name>` field specifies a particular functionality that the routine is designed for, for example, `NewTask`, `DeleteTask`.

Convolution and Correlation Data Types

All convolution or correlation routines use the following types for specifying data objects:

Type	Data Object
FORTRAN 77: `INTEGER*4 task(2)` Fortran 90: `TYPE(VSL_CONV_TASK)`	Pointer to a task descriptor for convolution
FORTRAN 77: `INTEGER*4 task(2)` Fortran 90: `TYPE(VSL_CORR_TASK)`	Pointer to a task descriptor for correlation
FORTRAN 77: `REAL*4` Fortran 90: `REAL(KIND=4)`	Input/output user real data in single precision
FORTRAN 77: `REAL*8` Fortran 90: `REAL(KIND=8)`	Input/output user real data in double precision
FORTRAN 77: `COMLEX*8` Fortran 90: `COMPLEX(KIND=4)`	Input/output user complex data in single precision
FORTRAN 77: `COMPLEX*16` Fortran 90: `COMPLEX(KIND=8)`	Input/output user complex data in double precision
FORTRAN 77: `INTEGER` Fortran 90: `INTEGER`	All other data

Generic integer type (without specifying the byte size) is used for all integer data.

NOTE
The actual size of the generic integer type is platform-dependent. Before you compile your application, set an appropriate byte size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*.

Convolution and Correlation Parameters

Basic parameters held by the task descriptor are assigned values when the task object is created, copied, or modified by task editors. Parameters of the correlation or convolution task are initially set up by task constructors when the task object is created. Parameter changes or additional settings are made by task editors. More parameters which define location of the data being convolved need to be specified when the task execution routine is invoked.

According to how the parameters are passed or assigned values, all of them can be categorized as either explicit (directly passed as routine parameters when a task object is created or executed) or optional (assigned some default or implicit values during task construction).

The following table lists all applicable parameters used in the Intel® oneAPI Math Kernel Library (oneMKL) convolution and correlation API.

Convolution and Correlation Task Parameters

Name	Category	Type	Default Value Label	Description
job	explicit	integer	Implied by the constructor name	Specifies whether the task relates to convolution or correlation
type	explicit	integer	Implied by the constructor name	Specifies the type (real or complex) of the input/output data. Set to real in the current version.
precision	explicit	integer	Implied by the constructor name	Specifies precision (single or double) of the input/output data to be provided in arrays *x*,*y*,*z*.
mode	explicit	integer	None	Specifies whether the convolution/ correlation computation should be done via Fourier transforms, or by a direct method, or by automatically choosing between the two. See `SetMode` for the list of named constants for this parameter.
method	optional	integer	"auto"	Hints at a particular computation method if several methods are available for the given *mode*. Setting this parameter to "auto" means that software will choose the best available method.
internal_precision	optional	integer	Set equal to the value of *precision*	Specifies precision of internal calculations. Can enforce double precision calculations even when input/output data are single precision. See `SetInternalPrecision` for the list of named constants for this parameter.
dims	explicit	integer	None	Specifies the rank (number of dimensions) of the user data provided in arrays *x*,*y*,*z*. Can be in the range from 1 to 7.
x,*y*	explicit	real arrays	None	Specify input data arrays. See Data Allocation for more information.
z	explicit	real array	None	Specifies output data array. See Data Allocation for more information.
xshape, *yshape*, *zshape*	explicit	integer arrays	None	Define shapes of the arrays *x*, *y*, *z*. See Data Allocation for more information.
xstride, *ystride*, *zstride*	explicit	integer arrays	None	Define strides within arrays *x*, *y*, *z*, that is specify the physical location of the input and output data in these arrays. See Data Allocation for more information.

Name	Category	Type	Default Value Label	Description
start	optional	integer array	Undefined	Defines the first element of the mathematical result that will be stored to output array *z*. See SetStart and Data Allocation for more information.
decimation	optional	integer array	Undefined	Defines how to thin out the mathematical result that will be stored to output array *z*. See SetDecimation and Data Allocation for more information.

Convolution and Correlation Task Status and Error Reporting

The task status is an integer value, which is zero if no error has been detected while processing the task, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings.

An error can be caused by invalid parameter values, a system fault like a memory allocation failure, or can be an internal error self-detected by the software.

Each task descriptor contains the current status of the task. When creating a task object, the constructor assigns the VSL_STATUS_OK status to the task. When processing the task afterwards, other routines such as editors or executors can change the task status if an error occurs and write a corresponding error code into the task status field.

Note that at the stage of creating a task or editing its parameters, the set of parameters may be inconsistent. The parameter consistency check is only performed during the task commitment operation, which is implicitly invoked before task execution or task copying. If an error is detected at this stage, task execution or task copying is terminated and the task descriptor saves the corresponding error code. Once an error occurs, any further attempts to process that task descriptor is terminated and the task keeps the same error code.

Normally, every convolution or correlation function (except DeleteTask) returns the status assigned to the task while performing the function operation.

The header files define symbolic names for the status codes. These names are defined as integer constants via the PARAMETER operators.

If there is no error, the VSL_STATUS_OK status is returned, which is defined as zero:

```
F90/F95:        INTEGER(KIND=4) VSL_STATUS_OK
                PARAMETER(VSL_STATUS_OK = 0)
```

In case of an error, a non-zero error code is returned, which indicates the origin of the failure. The following status codes for the convolution/correlation error codes are pre-defined in the header files.

Convolution/Correlation Status Codes

Status Code	Description
VSL_CC_ERROR_NOT_IMPLEMENTED	Requested functionality is not implemented.
VSL_CC_ERROR_ALLOCATION_FAILURE	Memory allocation failure.
VSL_CC_ERROR_BAD_DESCRIPTOR	Task descriptor is corrupted.
VSL_CC_ERROR_SERVICE_FAILURE	A service function has failed.
VSL_CC_ERROR_EDIT_FAILURE	Failure while editing the task.
VSL_CC_ERROR_EDIT_PROHIBITED	You cannot edit this parameter.

Status Code	Description
VSL_CC_ERROR_COMMIT_FAILURE	Task commitment has failed.
VSL_CC_ERROR_COPY_FAILURE	Failure while copying the task.
VSL_CC_ERROR_DELETE_FAILURE	Failure while deleting the task.
VSL_CC_ERROR_BAD_ARGUMENT	Bad argument or task parameter.
VSL_CC_ERROR_JOB	Bad parameter: *job*.
SL_CC_ERROR_KIND	Bad parameter: *kind*.
VSL_CC_ERROR_MODE	Bad parameter: *mode*.
VSL_CC_ERROR_METHOD	Bad parameter: *method*.
VSL_CC_ERROR_TYPE	Bad parameter: *type*.
VSL_CC_ERROR_EXTERNAL_PRECISION	Bad parameter: *external_precision*.
VSL_CC_ERROR_INTERNAL_PRECISION	Bad parameter: *internal_precision*.
VSL_CC_ERROR_PRECISION	Incompatible external/internal precisions.
VSL_CC_ERROR_DIMS	Bad parameter: *dims*.
VSL_CC_ERROR_XSHAPE	Bad parameter: *xshape*.
VSL_CC_ERROR_YSHAPE	Bad parameter: *yshape*.
	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or >nmax.
VSL_CC_ERROR_ZSHAPE	Bad parameter: *zshape*.
VSL_CC_ERROR_XSTRIDE	Bad parameter: *xstride*.
VSL_CC_ERROR_YSTRIDE	Bad parameter: *ystride*.
VSL_CC_ERROR_ZSTRIDE	Bad parameter: *zstride*.
VSL_CC_ERROR_X	Bad parameter: *x*.
VSL_CC_ERROR_Y	Bad parameter: *y*.
VSL_CC_ERROR_Z	Bad parameter: *z*.
VSL_CC_ERROR_START	Bad parameter: *start*.
VSL_CC_ERROR_DECIMATION	Bad parameter: *decimation*.
VSL_CC_ERROR_OTHER	Another error.

Convolution and Correlation Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters. No additional parameter adjustment is typically required and other routines can use the task object.

Intel® MKL implementation of the convolution and correlation API provides two different forms of constructors: a general form and an X-form. X-form constructors work in the same way as the general form constructors but also assign particular data to the first operand vector used in the convolution or correlation operation (stored in array *x*).

Using X-form constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector held in array *x* against different vectors held in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Each constructor routine has an associated one-dimensional version that provides algorithmic and computational benefits.

NOTE
If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

The Table "Task Constructors" lists available task constructors:

Task Constructors

Routine	Description
vslConvNewTask/vslCorrNewTask	Creates a new convolution or correlation task descriptor for a multidimensional case.
vslConvNewTask1D/ vslCorrNewTask1D	Creates a new convolution or correlation task descriptor for a one-dimensional case.
vslConvNewTaskX/vslCorrNewTaskX	Creates a new convolution or correlation task descriptor as an X-form for a multidimensional case.
vslConvNewTaskX1D/ vslCorrNewTaskX1D	Creates a new convolution or correlation task descriptor as an X-form for a one-dimensional case.

vslConvNewTask/vslCorrNewTask

Creates a new convolution or correlation task descriptor for multidimensional case.

Syntax

```
status = vslsconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsldconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslcconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslzconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslscorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsldcorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslccorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslzcorrnewtask(task, mode, dims, xshape, yshape, zshape)
```

Include Files

- `mkl.fi`, `mkl_vsl.f90`

Input Parameters

Name	Type	Description
mode	FORTRAN 77: INTEGER Fortran 90: INTEGER	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table "Values of mode parameter" for a list of possible values.
dims	FORTRAN 77: INTEGER Fortran 90: INTEGER	Rank of user data. Specifies number of dimensions for the input and output arrays *x*, *y*, and *z* used during the execution stage. Must be in the range from 1 to 7. The value is explicitly assigned by the constructor.
xshape	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*)	Defines the shape of the input data for the source array *x*. See Data Allocation for more information.
yshape	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*)	Defines the shape of the input data for the source array *y*. See Data Allocation for more information.
zshape	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*)	Defines the shape of the output data to be stored in array *z*. See Data Allocation for more information.

Output Parameters

Name	Type	Description
task	FORTRAN 77: INTEGER*4 task(2) for vslsconvnewtask, vsldconvnewtask, vslcconvnewtask, vslzconvnewtask INTEGER*4 task(2) for vslscorrnewtask, vsldcorrnewtask, vslccorrnewtask, vslzcorrnewtask Fortran 90: TYPE(VSL_CONV_TASK) for vslsconvnewtask, vsldconvnewtask, vslcconvnewtask, vslzconvnewtask TYPE(VSL_CORR_TASK) for vslscorrnewtask, vsldcorrnewtask, vslccorrnewtask, vslzcorrnewtask	Pointer to the task descriptor if created successfully or NULL pointer otherwise.

Name	Type	Description
status	FORTRAN 77: INTEGER Fortran 90: INTEGER	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

Each vslConvNewTask/vslCorrNewTask constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see Table "Convolution and Correlation Task Parameters").

The parameters *xshape*, *yshape*, and *zshape* define the shapes of the input and output data provided by the arrays *x*, *y*, and *z*, respectively. Each shape parameter is an array of integers with its length equal to the value of *dims*. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter *dims* is 1, then *xshape*, *yshape*, *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. Note that values of shape parameters may differ from physical shapes of arrays *x*, *y*, and *z* if non-trivial strides are assigned.

If the constructor fails to create a task descriptor, it returns a NULL task pointer.

vslConvNewTask1D/vslCorrNewTask1D

Creates a new convolution or correlation task descriptor for one-dimensional case.

Syntax

```
status = vslsconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslcconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslzconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslscorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldcorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vslccorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vslzcorrnewtask1d(task, mode, xshape, yshape, zshape)
```

Include Files

Input Parameters

Name	Type	Description
mode	INTEGER	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table "Values of mode parameter" for a list of possible values.
xshape	INTEGER	Defines the length of the input data sequence for the source array *x*. See Data Allocation for more information.
yshape	INTEGER	Defines the length of the input data sequence for the source array *y*. See Data Allocation for more information.

Name	Type	Description
zshape	INTEGER	Defines the length of the output data sequence to be stored in array *z*. See Data Allocation for more information.

Output Parameters

Name	Type	Description
task	FORTRAN 77: INTEGER*4 task(2) for vslsconvnewtask1d, vsldconvnewtask1d, vslcconvnewtask1d, vslzconvnewtask1d INTEGER*4 task(2) for vslscorrnewtask1d, vsldcorrnewtask1d, vslccorrnewtask1d, vslzcorrnewtask1d TYPE(VSL_CONV_TASK) for vslsconvnewtask1d, vsldconvnewtask1d, vslcconvnewtask1d, vslzconvnewtask1d TYPE(VSL_CORR_TASK) for vslscorrnewtask1d, vsldcorrnewtask1d, vslccorrnewtask1d, vslzcorrnewtask1d VSLCorrTaskPtr* for vslsCorrNewTask1D, vsldCorrNewTask1D, vslcCorrNewTask1D, vslzCorrNewTask1D	Pointer to the task descriptor if created successfully or NULL pointer otherwise.
status	INTEGER	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

Each vslConvNewTask1D/vslCorrNewTask1D constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see Table "Convolution and Correlation Task Parameters"). Unlike vslConvNewTask/vslCorrNewTask, these routines represent a special one-dimensional version of the constructor which assumes that the value of the parameter *dims* is 1. The parameters *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. You explicitly assign the shape parameters when calling the constructor.

vslConvNewTaskX/vslCorrNewTaskX

Creates a new convolution or correlation task descriptor for multidimensional case and assigns source data to the first operand vector.

Syntax

```
status = vslsconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vsldconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslcconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslzconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslscorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vsldcorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslccorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslzcorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
```

Include Files

Input Parameters

Name	Type	Description
mode	INTEGER	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table "Values of mode parameter" for a list of possible values.
dims	INTEGER	Rank of user data. Specifies number of dimensions for the input and output arrays *x*, *y*, and *z* used during the execution stage. Must be in the range from 1 to 7. The value is explicitly assigned by the constructor.
xshape	INTEGER, DIMENSION(*)	Defines the shape of the input data for the source array *x*. See Data Allocation for more information.
yshape	INTEGER, DIMENSION(*)	Defines the shape of the input data for the source array *y*. See Data Allocation for more information.
zshape	INTEGER, DIMENSION(*)	Defines the shape of the output data to be stored in array *z*.See Data Allocation for more information.
x	REAL*8 for real data in double precision flavors, COMPLEX*8 for complex data in single precision flavors, COMPLEX*16 for complex data in double precision flavors REAL(KIND=4), DIMENSION (*) for real data in single precision flavors,	Pointer to the array containing input data for the first operand vector.See Data Allocation for more information.

Name	Type	Description
	`REAL(KIND=8), DIMENSION (*)` for real data in double precision flavors, `COMPLEX(KIND=4), DIMENSION (*)` for complex data in single precision flavors, `COMPLEX(KIND=8), DIMENSION (*)` for complex data in double precision flavors	
xstride	`INTEGER, DIMENSION(*)`	Strides for input data in the array *x*.

Output Parameters

Name	Type	Description

task	`INTEGER*4 task(2)` for `vslscorrnewtaskx`, `vsldcorrnewtaskx`, `vslccorrnewtaskx`, `vslzcorrnewtaskx`
	`TYPE(VSL_CONV_TASK)` for `vslsconvnewtaskx`, `vsldconvnewtaskx`, `vslcconvnewtaskx`, `vslzconvnewtaskx`
	`TYPE(VSL_CORR_TASK)` for `vslscorrnewtaskx`, `vsldcorrnewtaskx`, `vslccorrnewtaskx`, `vslzcorrnewtaskx`
	`VSLCorrTaskPtr*` for `vslsCorrNewTaskX`, `vsldCorrNewTaskX`, `vslcCorrNewTaskX`, `vslzCorrNewTaskX`
		Pointer to the task descriptor if created successfully or `NULL` pointer otherwise.

status	`INTEGER`	Set to `VSL_STATUS_OK` if the task is created successfully or set to non-zero error code otherwise.

Description

Each `vslConvNewTaskX`/`vslCorrNewTaskX` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see Table "Convolution and Correlation Task Parameters").

Unlike vslConvNewTask/vslCorrNewTask, these routines represent the so called X-form version of the constructor, which means that in addition to creating the task descriptor they assign particular data to the first operand vector in array *x* used in convolution or correlation operation. The task descriptor created by the vslConvNewTaskX/vslCorrNewTaskX constructor keeps the pointer to the array *x* all the time, that is, until the task object is deleted by one of the destructor routines (see vslConvDeleteTask/vslCorrDeleteTask).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters *xshape*, *yshape*, and *zshape* define the shapes of the input and output data provided by the arrays *x*, *y*, and *z*, respectively. Each shape parameter is an array of integers with its length equal to the value of *dims*. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter *dims* is 1, then *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. Note that values of shape parameters may differ from physical shapes of arrays *x*, *y*, and *z* if non-trivial strides are assigned.

The stride parameter *xstride* specifies the physical location of the input data in the array *x*. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *xstride* is s, then only every s^{th} element of the array *x* will be used to form the input sequence. The stride value must be positive or negative but not zero.

vslConvNewTaskX1D/vslCorrNewTaskX1D

Creates a new convolution or correlation task descriptor for one-dimensional case and assigns source data to the first operand vector.

Syntax

status = vslsconvnewtaskx1d(*task*, *mode*, *xshape*, *yshape*, *zshape*, *x*, *xstride*)

status = vsldconvnewtaskx1d(*task*, *mode*, *xshape*, *yshape*, *zshape*, *x*, *xstride*)

status = vslcconvnewtaskx1d(*task*, *mode*, *xshape*, *yshape*, *zshape*, *x*, *xstride*)

status = vslzconvnewtaskx1d(*task*, *mode*, *xshape*, *yshape*, *zshape*, *x*, *xstride*)

status = vslscorrnewtaskx1d(*task*, *mode*, *xshape*, *yshape*, *zshape*, *x*, *xstride*)

status = vsldcorrnewtaskx1d(*task*, *mode*, *xshape*, *yshape*, *zshape*, *x*, *xstride*)

status = vslccorrnewtaskx1d(*task*, *mode*, *xshape*, *yshape*, *zshape*, *x*, *xstride*)

status = vslzcorrnewtaskx1d(*task*, *mode*, *xshape*, *yshape*, *zshape*, *x*, *xstride*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
mode	INTEGER	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table "Values of mode parameter" for a list of possible values.
xshape	INTEGER	Defines the length of the input data sequence for the source array *x*. See Data Allocation for more information.

Name	Type	Description
yshape	INTEGER	Defines the length of the input data sequence for the source array *y*. See Data Allocation for more information.
zshape	INTEGER	Defines the length of the output data sequence to be stored in array *z*. See Data Allocation for more information.
x	REAL*8 for real data in double precision flavors, COMPLEX*8 for complex data in single precision flavors, COMPLEX*16 for complex data in double precision flavors REAL(KIND=4), DIMENSION (*) for real data in single precision flavors, REAL(KIND=8), DIMENSION (*) for real data in double precision flavors, COMPLEX(KIND=4), DIMENSION (*) for complex data in single precision flavors, COMPLEX(KIND=8), DIMENSION (*) for complex data in double precision flavors	Pointer to the array containing input data for the first operand vector. See Data Allocation for more information.
xstride	INTEGER	Stride for input data sequence in the array*x*.

Output Parameters

Name	Type	Description
task	INTEGER*4 task(2) for vslscorrnewtaskx1d, vsldcorrnewtaskx1d, vslccorrnewtaskx1d, vslzcorrnewtaskx1d TYPE(VSL_CONV_TASK) for vslsconvnewtaskx1d, vsldconvnewtaskx1d, vslcconvnewtaskx1d, vslzconvnewtaskx1d TYPE(VSL_CORR_TASK) for vslscorrnewtaskx1d, vsldcorrnewtaskx1d, vslccorrnewtaskx1d, vslzcorrnewtaskx1d	Pointer to the task descriptor if created successfully or NULL pointer otherwise.

Name	Type	Description
	`VSLCorrTaskPtr*` for `vslsCorrNewTaskX1D`, `vsldCorrNewTaskX1D`, `vslcCorrNewTaskX1D`, `vslzCorrNewTaskX1D`	
status	`INTEGER`	Set to `VSL_STATUS_OK` if the task is created successfully or set to non-zero error code otherwise.

Description

Each `vslConvNewTaskX1D`/`vslCorrNewTaskX1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see Table "Convolution and Correlation Task Parameters").

These routines represent a special one-dimensional version of the so called X-form of the constructor. This assumes that the value of the parameter *dims* is 1 and that in addition to creating the task descriptor, constructor routines assign particular data to the first operand vector in array *x* used in convolution or correlation operation. The task descriptor created by the `vslConvNewTaskX1D`/`vslCorrNewTaskX1D` constructor keeps the pointer to the array *x* all the time, that is, until the task object is deleted by one of the destructor routines (see `vslConvDeleteTask`/`vslCorrDeleteTask`).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. You explicitly assign the shape parameters when calling the constructor.

The stride parameters *xstride* specifies the physical location of the input data in the array *x* and is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *xstride* is `s`, then only every s^{th} element of the array *x* will be used to form the input sequence. The stride value must be positive or negative but not zero.

Convolution and Correlation Task Editors

Task editors in convolution and correlation API of Intel® oneAPI Math Kernel Library (oneMKL) are routines intended for setting up or changing the following task parameters (seeTable "Convolution and Correlation Task Parameters"):

- *mode*
- *internal_precision*
- *start*
- *decimation*

For setting up or changing each of the above parameters, a separate routine exists.

NOTE
Fields of the task descriptor structure are accessible only through the set of task editor routines provided with the software.

The work data computed during the last commitment process may become invalid with respect to new parameter settings. That is why after applying any of the editor routines to change the task descriptor settings, the task loses its commitment status and goes through the full commitment process again during the next execution or copy operation. For more information on task commitment, see the Introduction to Convolution and Correlation.

Table "Task Editors" lists available task editors.

Task Editors

Routine	Description
vslConvSetMode/vslCorrSetMode	Changes the value of the parameter *mode* for the operation of convolution or correlation.
vslConvSetInternalPrecision/ vslCorrSetInternalPrecision	Changes the value of the parameter *internal_precision* for the operation of convolution or correlation.
vslConvSetStart/vslCorrSetStart	Sets the value of the parameter *start* for the operation of convolution or correlation.
vslConvSetDecimation/ vslCorrSetDecimation	Sets the value of the parameter *decimation* for the operation of convolution or correlation.

NOTE
You can use the NULL task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

vslConvSetMode/vslCorrSetMode

Changes the value of the parameter mode in the convolution or correlation task descriptor.

Syntax

status = vslconvsetmode(*task*, *newmode*)

status = vslcorrsetmode(*task*, *newmode*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
task	FORTRAN 77: INTEGER*4 task(2) for vslconvsetmode INTEGER*4 task(2) for vslcorrsetmode Fortran 90: TYPE(VSL_CONV_TASK) for vslconvsetmode TYPE(VSL_CORR_TASK) for vslcorrsetmode	Pointer to the task descriptor.

Name	Type	Description
newmode	FORTRAN 77: INTEGER Fortran 90: INTEGER	New value of the parameter mode.

Output Parameters

Name	Type	Description
status	FORTRAN 77: INTEGER Fortran 90: INTEGER	Current status of the task.

Description

This function is declared in mkl_vsl.f90 for the Fortran interface.

The function routine changes the value of the parameter mode for the operation of convolution or correlation. This parameter defines whether the computation should be done via Fourier transforms of the input/output data or using a direct algorithm. Initial value for mode is assigned by a task constructor.

Predefined values for the mode parameter are as follows:

Values of *mode* parameter

Value	Purpose
VSL_CONV_MODE_FFT	Compute convolution by using fast Fourier transform.
VSL_CORR_MODE_FFT	Compute correlation by using fast Fourier transform.
VSL_CONV_MODE_DIRECT	Compute convolution directly.
VSL_CORR_MODE_DIRECT	Compute correlation directly.
VSL_CONV_MODE_AUTO	Automatically choose direct or Fourier mode for convolution.
VSL_CORR_MODE_AUTO	Automatically choose direct or Fourier mode for correlation.

vslConvSetInternalPrecision/vslCorrSetInternalPrecision

Changes the value of the parameter internal_precision in the convolution or correlation task descriptor.

Syntax

```
status = vslconvsetinternalprecision(task, precision)
status = vslcorrsetinternalprecision(task, precision)
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description

task	`INTEGER*4 task(2)` for `vslcorrsetinternalprecision`
	`TYPE(VSL_CONV_TASK)` for `vslconvsetinternalprecision`
	`TYPE(VSL_CORR_TASK)` for `vslcorrsetinternalprecision`
		Pointer to the task descriptor.

precision	`INTEGER`	New value of the parameter *internal_precision*.

Output Parameters

Name	Type	Description
status	`INTEGER`	Current status of the task.

Description

The `vslConvSetInternalPrecision`/`vslCorrSetInternalPrecision` routine changes the value of the parameter *internal_precision* for the operation of convolution or correlation. This parameter defines whether the internal computations of the convolution or correlation result should be done in single or double precision. Initial value for *internal_precision* is assigned by a task constructor and set to either "single" or "double" according to the particular flavor of the constructor used.

Changing the *internal_precision* can be useful if the default setting of this parameter was "single" but you want to calculate the result with double precision even if input and output data are represented in single precision.

Predefined values for the *internal_precision* input parameter are as follows:

Values of *internal_precision* Parameter

Value	Purpose
`VSL_CONV_PRECISION_SINGLE`	Compute convolution with single precision.
`VSL_CORR_PRECISION_SINGLE`	Compute correlation with single precision.
`VSL_CONV_PRECISION_DOUBLE`	Compute convolution with double precision.
`VSL_CORR_PRECISION_DOUBLE`	Compute correlation with double precision.

vslConvSetStart/vslCorrSetStart

Changes the value of the parameter start in the convolution or correlation task descriptor.

Syntax

```
status = vslconvsetstart(task, start)
status = vslcorrsetstart(task, start)
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
task	INTEGER*4 task(2) for vslcorrsetstart TYPE(VSL_CONV_TASK) for vslconvsetstart TYPE(VSL_CORR_TASK) for vslcorrsetstart	Pointer to the task descriptor.
start	INTEGER, DIMENSION (*)	New value of the parameter *start*.

Output Parameters

Name	Type	Description
status	INTEGER	Current status of the task.

Description

The vslConvSetStart/vslCorrSetStart routine sets the value of the parameter *start* for the operation of convolution or correlation. In a one-dimensional case, this parameter points to the first element in the mathematical result that should be stored in the output array. In a multidimensional case, *start* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see Data Allocation.

During the initial task descriptor construction, the default value for *start* is undefined and this parameter is not used. Therefore the only way to set and use the *start* parameter is via assigning it some value by one of the vslConvSetStart/vslCorrSetStart routines.

vslConvSetDecimation/vslCorrSetDecimation

Changes the value of the parameter decimation in the convolution or correlation task descriptor.

Syntax

status = vslconvsetdecimation(*task*, *decimation*)

status = vslcorrsetdecimation(*task*, *decimation*)

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
task	INTEGER*4 task(2) for vslcorrsetdecimation	Pointer to the task descriptor.

Name	Type	Description
	`TYPE(VSL_CONV_TASK)` for `vslconvsetdecimation` `TYPE(VSL_CORR_TASK)` for `vslcorrsetdecimation`	
decimation	`INTEGER, DIMENSION (*)`	New value of the parameter *decimation*.

Output Parameters

Name	Type	Description
status	`INTEGER`	Current status of the task.

Description

The routine sets the value of the parameter *decimation* for the operation of convolution or correlation. This parameter determines how to thin out the mathematical result of convolution or correlation before writing it into the output data array. For example, in a one-dimensional case, if *decimation* = *d* > 1, only every *d*-th element of the mathematical result is written to the output array *z*. In a multidimensional case, *decimation* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see Data Allocation.

During the initial task descriptor construction, the default value for *decimation* is undefined and this parameter is not used. Therefore the only way to set and use the *decimation* parameter is via assigning it some value by one of the `vslSetDecimation` routines.

Task Execution Routines

Task execution routines compute convolution or correlation results based on parameters held by the task descriptor and on the user data supplied for input vectors.

After you create and adjust a task, you can execute it multiple times by applying to different input/output data of the same type, precision, and shape.

Intel® oneAPI Math Kernel Library (oneMKL) provides the following forms of convolution/correlation execution routines:

- **General form** executors that use the task descriptor created by the general form constructor and expect to get two source data arrays *x* and *y* on input
- **X-form** executors that use the task descriptor created by the X-form constructor and expect to get only one source data array *y* on input because the first array *x* has been already specified on the construction stage

When the task is executed for the first time, the execution routine includes a task commitment operation, which involves two basic steps: parameters consistency check and preparation of auxiliary data (for example, this might be the calculation of Fourier transform for input data).

Each execution routine has an associated one-dimensional version that provides algorithmic and computational benefits.

NOTE
You can use the `NULL` task pointer in calls to execution routines. In this case, the routine is terminated and no system crash occurs.

If the task is executed successfully, the execution routine returns the zero status code. If an error is detected, the execution routine returns an error code which signals that a specific error has occurred. In particular, an error status code is returned in the following cases:

- if the task pointer is `NULL`
- if the task descriptor is corrupted
- if calculation has failed for some other reason.

> **NOTE**
> Intel® MKL does not control floating-point errors, like overflow or gradual underflow, or operations with NaNs, etc.

If an error occurs, the task descriptor stores the error code.

The table below lists all task execution routines.

Task Execution Routines

Routine	Description
vslConvExec/vslCorrExec	Computes convolution or correlation for a multidimensional case.
vslConvExec1D/vslCorrExec1D	Computes convolution or correlation for a one-dimensional case.
vslConvExecX/vslCorrExecX	Computes convolution or correlation as X-form for a multidimensional case.
vslConvExecX1D/vslCorrExecX1D	Computes convolution or correlation as X-form for a one-dimensional case.

vslConvExec/vslCorrExec

Computes convolution or correlation for multidimensional case.

Syntax

```
status = vslsconvexec(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslcconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslzconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslscorrexec(task, x, xstride, y, ystride, z, zstride)
status = vsldcorrexec(task, x, xstride, y, ystride, z, zstride)
status = vslccorrexec(task, x, xstride, y, ystride, z, zstride)
status = vslzcorrexec(task, x, xstride, y, ystride, z, zstride)
```

Input Parameters

Name	Type	Description
task	`INTEGER*4 task(2)` for `vslscorrexec`, `vsldcorrexec`, `vslccorrexec`, `vslzcorrexec`	Pointer to the task descriptor

Name	Type	Description
	`TYPE(VSL_CONV_TASK)` for `vslsconvexec`, `vsldconvexec`, `vslcconvexec`, `vslzconvexec`	
	`TYPE(VSL_CORR_TASK)` for `vslscorrexec`, `vsldcorrexec`, `vslccorrexec`, `vslzcorrexec`	
	`VSLCorrTaskPtr` for `vslsCorrExec`, `vsldCorrExec`, `vslcCorrExec`, `vslzCorrExec`	
x, *y*	`REAL*8` for `vsldconvexec` and `vsldcorrexec`,	Pointers to arrays containing input data. See Data Allocation for more information.
	`COMPLEX*8` for`vslcconvexec` and `vslccorrexec`,	
	`COMPLEX*16` for`vslzconvexec` and `vslzcorrexec`	
	`REAL(KIND=4), DIMENSION(*)` for `vslsconvexec` and `vslscorrexec`,	
	`REAL(KIND=8), DIMENSION(*)` for `vsldconvexec` and `vsldcorrexec`,	
	`COMPLEX(KIND=4), DIMENSION(*)` for`vslcconvexec` and `vslccorrexec`,	
	`COMPLEX(KIND=8), DIMENSION(*)` for `vslzconvexec` and `vslzcorrexec`	
xstride, *ystride*, *zstride*	`INTEGER, DIMENSION (*)`	Strides for input and output data. For more information, see stride parameters.

Output Parameters

Name	Type	Description
z	`REAL*8` for `vsldconvexec` and `vsldcorrexec`,	Pointer to the array that stores output data. See Data Allocation for more information.
	`COMPLEX*8` for`vslcconvexec` and `vslccorrexec`,	
	`COMPLEX*16` for`vslzconvexec` and `vslzcorrexec`	
	`REAL(KIND=4), DIMENSION(*)` for `vslsconvexec` and `vslscorrexec`,	

Name	Type	Description
	`REAL(KIND=8), DIMENSION(*)` for `vsldconvexec` and `vsldcorrexec`, `COMPLEX(KIND=4), DIMENSION(*)` for`vslcconvexec` and `vslccorrexec`, `COMPLEX(KIND=8), DIMENSION(*)` for `vslzconvexec` and `vslzcorrexec`	
status	INTEGER	Set to `VSL_STATUS_OK` if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the `vslConvExec`/`vslCorrExec` routines computes convolution or correlation of the data provided by the arrays *x* and *y* and then stores the results in the array *z*. Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTask`/`vslCorrNewTask` constructor and pointed to by *task*. If *task* is `NULL`, no operation is done.

The stride parameters *xstride*, *ystride*, and *zstride* specify the physical location of the input and output data in the arrays *x*, *y*, and *z*, respectively. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *zstride* is `s`, then only every s^{th} element of the array *z* will be used to store the output data. The stride value must be positive or negative but not zero.

vslConvExec1D/vslCorrExec1D

Computes convolution or correlation for one-dimensional case.

Syntax

```
status = vslsconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslcconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslzconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslscorrexec1d(task, x, xstride, y, ystride, z, zstride)
status = vsldcorrexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslccorrexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslzcorrexec1d(task, x, xstride, y, ystride, z, zstride)
```

Include Files

- `mkl.fi`, `mkl_vsl.f90`

Input Parameters

Name	Type	Description

task	`INTEGER*4 task(2)` for `vslscorrexec1d`, `vsldcorrexec1d`, `vslccorrexec1d`, `vslzcorrexec1d`
	`TYPE(VSL_CONV_TASK)` for `vslsconvexec1d`, `vsldconvexec1d`, `vslcconvexec1d`, `vslzconvexec1d`
	`TYPE(VSL_CORR_TASK)` for `vslscorrexec1d`, `vsldcorrexec1d`, `vslccorrexec1d`, `vslzcorrexec1d`
	`VSLCorrTaskPtr` for `vslsCorrExec1D`, `vsldCorrExec1D`, `vslcCorrExec1D`, `vslzCorrExec1D`
		Pointer to the task descriptor.

x, *y*	`REAL*8` for `vsldconvexec1d` and `vsldcorrexec1d`,
	`COMPLEX*8` for`vslcconvexec1d` and `vslccorrexec1d`,
	`COMPLEX*16` for`vslzconvexec1d` and `vslzcorrexec1d`
	`REAL(KIND=4), DIMENSION(*)` for `vslsconvexec1d` and `vslscorrexec1d`,
	`REAL(KIND=8), DIMENSION(*)` for `vsldconvexec1d` and `vsldcorrexec1d`,
	`COMPLEX(KIND=4), DIMENSION(*)` for`vslcconvexec1d` and `vslccorrexec1d`,
	`COMPLEX(KIND=8), DIMENSION(*)` for `vslzconvexec1d` and `vslzcorrexec1d`
		Pointers to arrays containing input data. See Data Allocation for more information.

xstride, *ystride*, *zstride*	`INTEGER`	Strides for input and output data. For more information, see stride parameters.

Output Parameters

Name	Type	Description
z	REAL*8 for vsldconvexec1d and vsldcorrexec1d, COMPLEX*8 forvslcconvexec1d and vslccorrexec1d, COMPLEX*16 forvslzconvexec1d and vslzcorrexec1d REAL(KIND=4), DIMENSION(*) for vslsconvexec1d and vslscorrexec1d, REAL(KIND=8), DIMENSION(*) for vsldconvexec1d and vsldcorrexec1d, COMPLEX(KIND=4), DIMENSION(*) forvslcconvexec1d and vslccorrexec1d, COMPLEX(KIND=8), DIMENSION(*) for vslzconvexec1d and vslzcorrexec1d	Pointer to the array that stores output data. See Data Allocation for more information.
status	INTEGER	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the vslConvExec1D/vslCorrExec1D routines computes convolution or correlation of the data provided by the arrays *x* and *y* and then stores the results in the array *z*. These routines represent a special one-dimensional version of the operation, assuming that the value of the parameter *dims* is 1. Using this version of execution routines can help speed up performance in case of one-dimensional data.

Parameters of the operation are read from the task descriptor created previously by a corresponding vslConvNewTask1D/vslCorrNewTask1D constructor and pointed to by *task*. If *task* is NULL, no operation is done.

vslConvExecX/vslCorrExecX

Computes convolution or correlation for multidimensional case with the fixed first operand vector.

Syntax

```
status = vslsconvexecx(task, y, ystride, z, zstride)
status = vsldconvexecx(task, y, ystride, z, zstride)
status = vslcconvexecx(task, y, ystride, z, zstride)
status = vslzconvexecx(task, y, ystride, z, zstride)
status = vslscorrexecx(task, y, ystride, z, zstride)
```

```
status = vsldcorrexecx(task, y, ystride, z, zstride)
status = vslccorrexecx(task, y, ystride, z, zstride)
status = vslzcorrexecx(task, y, ystride, z, zstride)
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
task	INTEGER*4 task(2) for vslscorrexecx, vsldcorrexecx, vslccorrexecx, vslzcorrexecx TYPE(VSL_CONV_TASK) for vslsconvexecx, vsldconvexecx, vslcconvexecx, vslzconvexecx TYPE(VSL_CORR_TASK) for vslscorrexecx, vsldcorrexecx, vslccorrexecx, vslzcorrexecx VSLCorrTaskPtr for vslsCorrExecX, vsldCorrExecX, vslcCorrExecX, vslzCorrExecX	Pointer to the task descriptor.
x ,*y*	REAL*8 for vsldconvexecx and vsldcorrexecx, COMPLEX*8 forvslcconvexecx and vslccorrexecx, COMPLEX*16 forvslzconvexecx and vslzcorrexecx REAL(KIND=4), DIMENSION(*) for vslsconvexecx and vslscorrexecx, REAL(KIND=8), DIMENSION(*) for vsldconvexecx and vsldcorrexecx, COMPLEX(KIND=4), DIMENSION (*) forvslcconvexecx and vslccorrexecx,	Pointer to array containing input data (for the second operand vector). See Data Allocation for more information.

Name	Type	Description
	COMPLEX(KIND=8), DIMENSION (*) for vslzconvexecx and vslzcorrexecx	
ystride ,*z* *stride*	INTEGER, DIMENSION (*)	Strides for input and output data. For more information, see stride parameters.

Output Parameters

Name	Type	Description
z	REAL*8 for vsldconvexecx and vsldcorrexecx, COMPLEX*8 forvslcconvexecx and vslccorrexecx, COMPLEX*16 forvslzconvexecx and vslzcorrexecx REAL(KIND=4), DIMENSION(*) for vslsconvexecx and vslscorrexecx, REAL(KIND=8), DIMENSION(*) for vsldconvexecx and vsldcorrexecx, COMPLEX(KIND=4), DIMENSION (*) forvslcconvexecx and vslccorrexecx, COMPLEX(KIND=8), DIMENSION (*) for vslzconvexecx and vslzcorrexecx	Pointer to the array that stores output data. See Data Allocation for more information.
status	INTEGER	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the vslConvExecX/vslCorrExecX routines computes convolution or correlation of the data provided by the arrays *x* and *y* and then stores the results in the array *z*. These routines represent a special version of the operation, which assumes that the first operand vector was set on the task construction stage and the task object keeps the pointer to the array *x*.

Parameters of the operation are read from the task descriptor created previously by a corresponding vslConvNewTaskX/vslCorrNewTaskX constructor and pointed to by *task*. If *task* is NULL, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

vslConvExecX1D/vslCorrExecX1D

Computes convolution or correlation for one-dimensional case with the fixed first operand vector.

Syntax

```
status = vslsconvexecx1d(task, y, ystride, z, zstride)
status = vsldconvexecx1d(task, y, ystride, z, zstride)
status = vslcconvexecx1d(task, y, ystride, z, zstride)
status = vslzconvexecx1d(task, y, ystride, z, zstride)
status = vslscorrexecx1d(task, y, ystride, z, zstride)
status = vsldcorrexecx1d(task, y, ystride, z, zstride)
status = vslccorrexecx1d(task, y, ystride, z, zstride)
status = vslzcorrexecx1d(task, y, ystride, z, zstride)
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
task	INTEGER*4 task(2) for vslscorrexecx1d, vsldcorrexecx1d, vslccorrexecx1d, vslzcorrexecx1d TYPE(VSL_CONV_TASK) for vslsconvexecx1d, vsldconvexecx1d, vslcconvexecx1d, vslzconvexecx1d TYPE(VSL_CORR_TASK) for vslscorrexecx1d, vsldcorrexecx1d, vslccorrexecx1d, vslzcorrexecx1d VSLCorrTaskPtr for vslsCorrExecX1D, vsldCorrExecX1D, vslcCorrExecX1D, vslzCorrExecX1D	Pointer to the task descriptor.
x, *y*	REAL*8 for vsldconvexecx1d and vsldcorrexecx1d, COMPLEX*8 forvslcconvexecx1d and vslccorrexecx1d,	Pointer to array containing input data (for the second operand vector). See Data Allocation for more information.

Name	Type	Description
	COMPLEX*16 forvslzconvexecx1d and vslzcorrexecx1d REAL(KIND=4), DIMENSION(*) for vslsconvexecx1d and vslscorrexecx1d, REAL(KIND=8), DIMENSION(*) for vsldconvexecx1d and vsldcorrexecx1d, COMPLEX(KIND=4), DIMENSION(*) forvslcconvexecx1d and vslccorrexecx1d, COMPLEX(KIND=8), DIMENSION(*) for vslzconvexecx1d and vslzcorrexecx1d	
ystride, *zstride*	INTEGER	Strides for input and output data. For more information, see stride parameters.

Output Parameters

Name	Type	Description
z	REAL*8 for vsldconvexecx1d and vsldcorrexecx1d, COMPLEX*8 forvslcconvexecx1d and vslccorrexecx1d, COMPLEX*16 forvslzconvexecx1d and vslzcorrexecx1d REAL(KIND=4), DIMENSION(*) for vslsconvexecx1d and vslscorrexecx1d, REAL(KIND=8), DIMENSION(*) for vsldconvexecx1d and vsldcorrexecx1d, COMPLEX(KIND=4), DIMENSION(*) forvslcconvexecx1d and vslccorrexecx1d, COMPLEX(KIND=8), DIMENSION(*) for vslzconvexecx1d and vslzcorrexecx1d	Pointer to the array that stores output data. See Data Allocation for more information.
status	INTEGER	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the vslConvExecX1D/vslCorrExecX1D routines computes convolution or correlation of one-dimensional (assuming that *dims* =1) data provided by the arrays *x* and *y* and then stores the results in the array *z*. These routines represent a special version of the operation, which expects that the first operand vector was set on the task construction stage.

Parameters of the operation are read from the task descriptor created previously by a corresponding vslConvNewTaskX1D/vslCorrNewTaskX1D constructor and pointed to by *task*. If *task* is NULL, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple one-dimensional convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Convolution and Correlation Task Destructors

Task destructors are routines designed for deleting task objects and deallocating memory.

vslConvDeleteTask/vslCorrDeleteTask

Destroys the task object and frees the memory.

Syntax

```
errcode = vslconvdeletetask(task)
errcode = vslcorrdeletetask(task)
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
task	INTEGER*4 task(2) for vslcorrdeletetask TYPE(VSL_CONV_TASK) for vslconvdeletetask TYPE(VSL_CORR_TASK) for vslcorrdeletetask	Pointer to the task descriptor.

Output Parameters

Name	Type	Description
errcode	INTEGER	Contains 0 if the task object is deleted successfully. Contains an error code if an error occurred.

Description

The vslConvDeleteTask/vslCorrvDeleteTask routine deletes the task descriptor object and frees any working memory and the memory allocated for the data structure. The task pointer is set to NULL.

Note that if the vslConvDeleteTask/vslCorrvDeleteTask routine does not delete the task successfully, the routine returns an error code. This error code has no relation to the task status code and does not change it.

NOTE
You can use the NULL task pointer in calls to destructor routines. In this case, the routine terminates with no system crash.

Convolution and Correlation Task Copiers

The routines are designed for copying convolution and correlation task descriptors.

vslConvCopyTask/vslCorrCopyTask

Copies a descriptor for convolution or correlation task.

Syntax

```
status = vslconvcopytask(newtask, srctask)
status = vslcorrcopytask(newtask, srctask)
```

Include Files

- mkl.fi, mkl_vsl.f90

Input Parameters

Name	Type	Description
srctask	INTEGER*4 srctask(2) for vslcorrcopytask TYPE(VSL_CONV_TASK) for vslconvcopytask TYPE(VSL_CORR_TASK) for vslcorrcopytask	Pointer to the source task descriptor.

Output Parameters

Name	Type	Description
newtask	INTEGER*4 srctask(2) for vslcorrcopytask TYPE(VSL_CONV_TASK) for vslconvcopytask TYPE(VSL_CORR_TASK) for vslcorrcopytask	Pointer to the new task descriptor.
status	INTEGER	Current status of the source task.

Description

If a task object *srctask* already exists, you can use an appropriate vslConvCopyTask/vslCorrCopyTask routine to make its copy in *newtask*. After the copy operation, both source and new task objects will become committed (see Introduction to Convolution and Correlation for information about task commitment). If the

source task was not previously committed, the commitment operation for this task is implicitly invoked before copying starts. If an error occurs during source task commitment, the task stores the error code in the status field. If an error occurs during copy operation, the routine returns a `NULL` pointer instead of a reference to a new task object.

Convolution and Correlation Usage Examples

This section demonstrates how you can use the Intel® oneAPI Math Kernel Library (oneMKL) routines to perform some common convolution and correlation operations both for single-threaded and multithreaded calculations. The following two sample functions`scond1` and `sconf1` simulate the convolution and correlation functions `SCOND` and `SCONF` found in IBM ESSL* library. The functions assume single-threaded calculations and can be used with C or C++ compilers.

Function scond1 for Single-Threaded Calculations

```
#include "mkl_vsl.h"

int scond1(
    float h[], int inch,
    float x[], int incx,
    float y[], int incy,
    int nh, int nx, int iy0, int ny)
{
    int status;
    VSLConvTaskPtr task;
    vslsConvNewTask1D(&task,VSL_CONV_MODE_DIRECT,nh,nx,ny);
    vslConvSetStart(task, &iy0);
    status = vslsConvExec1D(task, h,inch, x,incx, y,incy);
    vslConvDeleteTask(&task);
    return status;
}
```

Function sconf1 for Single-Threaded Calculations

```
#include "mkl_vsl.h"
int sconf1(
    int init,
    float h[], int inc1h,
    float x[], int inc1x, int inc2x,
    float y[], int inc1y, int inc2y,
    int nh, int nx, int m, int iy0, int ny,
    void* aux1, int naux1, void* aux2, int naux2)
{
    int status;
    /* assume that aux1!=0 and naux1 is big enough */
    VSLConvTaskPtr* task = (VSLConvTaskPtr*)aux1;
    if (init != 0)
        /* initialization: */
        status = vslsConvNewTaskX1D(task,VSL_CONV_MODE_FFT,
         nh,nx,ny, h,inc1h);
    if (init == 0) {
        /* calculations: */
        int i;
        vslConvSetStart(*task, &iy0);
        for (i=0; i<m; i++) {
         float* xi = &x[inc2x * i];
         float* yi = &y[inc2y * i];
         /* task is implicitly committed at i==0 */
         status = vslsConvExecX1D(*task, xi, inc1x, yi, inc1y);
        };
    };
    vslConvDeleteTask(task);
    return status;
}
```

Using Multiple Threads

For functions such as `sconf1` described in the previous example, parallel calculations may be more preferable instead of cycling. If `m>1`, you can use multiple threads for invoking the task execution against different data sequences. For such cases, use task copy routines to create `m` copies of the task object before the calculations stage and then run these copies with different threads. Ensure that you make all necessary parameter adjustments for the task (using Task Editors) before copying it.

The sample code in this case may look as follows:

```
if (init == 0) {
    int i, status, ss[M];
    VSLConvTaskPtr tasks[M];
    /* assume that M is big enough */
    . . .
    vslConvSetStart(*task, &iy0);
    . . .
    for (i=0; i<m; i++)
        /* implicit commitment at i==0 */
        vslConvCopyTask(&tasks[i],*task);
    . . .
```

Then, `m` threads may be started to execute different copies of the task:

```
. . .
        float* xi = &x[inc2x * i];
        float* yi = &y[inc2y * i];
        ss[i]=vslsConvExecX1D(tasks[i], xi,inc1x, yi,inc1y);
    . . .
```

And finally, after all threads have finished the calculations, overall status should be collected from all task objects. The following code signals the first error found, if any:

```
    . . .
    for (i=0; i<m; i++) {
        status = ss[i];
        if (status != 0) /* 0 means "OK" */
            break;
    };
    return status;
}; /* end if init==0 */
```

Execution routines modify the task internal state (fields of the task structure). Such modifications may conflict with each other if different threads work with the same task object simultaneously. That is why different threads must use different copies of the task.

Convolution and Correlation Mathematical Notation and Definitions

The following notation is necessary to explain the underlying mathematical definitions used in the text:

$\mathbf{R} = (-\infty, +\infty)$	The set of real numbers.
$\mathbf{Z} = \{0, \pm1, \pm2, \ldots\}$	The set of integer numbers.
$\mathbf{Z}^N = \mathbf{Z} \times \ldots \times \mathbf{Z}$	The set of N-dimensional series of integer numbers.
$p = (p_1, \ldots, p_N) \in \mathbf{Z}^N$	N-dimensional series of integers.
$u:\mathbf{Z}^N \to \mathbf{R}$	Function u with arguments from $\mathbf{Z}^N$ and values from $\mathbf{R}$.
$u(p) = u(p_1, \ldots, p_N)$	The value of the function u for the argument $(p_1, \ldots, p_N)$.
$w = u*v$	Function w is the convolution of the functions u, v.
$w = u \bullet v$	Function w is the correlation of the functions u, v.

Given series $p, q \in \mathbf{Z}^N$:

- series $r = p + q$ is defined as $r^n = p^n + q^n$ for every $n=1,\ldots,N$
- series $r = p - q$ is defined as $r^n = p^n - q^n$ for every $n=1,\ldots,N$
- series $r = \sup\{p, q\}$ is defines as $r^n = \max\{p^n, q^n\}$ for every $n=1,\ldots,N$
- series $r = \inf\{p, q\}$ is defined as $r^n = \min\{p^n, q^n\}$ for every $n=1,\ldots,N$
- inequality $p \le q$ means that $p^n \le q^n$ for every $n=1,\ldots,N$.

A function $u(p)$ is called a finite function if there exist series $P^{min}, P^{max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0$$

implies

$$P^{min} \le p \le P^{max}.$$

Operations of convolution and correlation are only defined for finite functions.

Consider functions u, v and series P^{min}, $P^{max}Q^{min}$, $Q^{max} \in \mathbf{Z}^N$ such that:

$u(p) \neq 0$ implies $P^{min} \le p \le P^{max}$.
$v(q) \neq 0$ implies $Q^{min} \le q \le Q^{max}$.

Definitions of linear correlation and linear convolution for functions u and v are given below.

Linear Convolution

If function $w = u*v$ is the convolution of u and v, then:

$w(r) \neq 0$ implies $\mathbf{R}^{min} \le r \le \mathbf{R}^{max}$,
where $\mathbf{R}^{min} = P^{min} + Q^{min}$ and $\mathbf{R}^{max} = P^{max} + Q^{max}$.

If $\mathbf{R}^{min} \le r \le \mathbf{R}^{max}$, then:

$w(r) = \sum u(t) \cdot v(r-t)$ is the sum for all $t \in \mathbf{Z}^N$ such that $\mathbf{T}^{min} \le t \le \mathbf{T}^{max}$,
where $\mathbf{T}^{min} = \sup\{P^{min}, r - Q^{max}\}$ and $\mathbf{T}^{max} = \inf\{P^{max}, r - Q^{min}\}$.

Linear Correlation

If function $w = u \bullet v$ is the correlation of u and v, then:

$w(r) \neq 0$ implies $\mathbf{R}^{min} \le r \le \mathbf{R}^{max}$,
where $\mathbf{R}^{min} = Q^{min} - P^{max}$ and $\mathbf{R}^{max} = Q^{max} - P^{min}$.

If $\mathbf{R}^{min} \le r \le \mathbf{R}^{max}$, then:

$w(r) = \sum u(t) \cdot v(r+t)$ is the sum for all $t \in \mathbf{Z}^N$ such that $\mathbf{T}^{min} \le t \le \mathbf{T}^{max}$,
where $\mathbf{T}^{min} = \sup\{P^{min}, Q^{min} - r\}$ and $\mathbf{T}^{max} = \inf\{P^{max}, Q^{max} - r\}$.

Representation of the functions *u*, *v*, *w*as the input/output data for the Intel® oneAPI Math Kernel Library (oneMKL) convolution and correlation functions is described in theData Allocation.

Convolution and Correlation Data Allocation

This section explains the relation between:

- mathematical finite functions *u*, *v*, *w* introduced in Mathematical Notation and Definitions;
- multi-dimensional input and output data vectors representing the functions *u*, *v*, *w*;
- arrays *u*, *v*, *w* used to store the input and output data vectors in computer memory

The convolution and correlation routine parameters that determine the allocation of input and output data are the following:

- Data arrays *x*, *y*, *z*
- Shape arrays *xshape*, *yshape*, *zshape*
- Strides within arrays *xstride*, *ystride*, *zstride*
- Parameters *start*, *decimation*

Finite Functions and Data Vectors

The finite functions *u(p)*, *v(q)*, and *w(r)* introduced above are represented as multi-dimensional vectors of input and output data:

$inputu(i_1,\ldots,i_{dims})$ for $u(p_1,\ldots,p_N)$

$inputv(j_1,\ldots,j_{dims})$ for $v(q_1,\ldots,q_N)$

$output(k_1,\ldots,k_{dims})$ for $w(r_1,\ldots,r_N)$.

Parameter *dims* represents the number of dimensions and is equal to N.

The parameters *xshape*, *yshape*, and *zshape* define the shapes of input/output vectors:

$inputu(i_1,\ldots,i_{dims})$ is defined if $1 \le i_n \le xshape(n)$ for every $n=1,\ldots,dims$

$inputv(j_1,\ldots,j_{dims})$ is defined if $1 \le j_n \le yshape(n)$ for every $n=1,\ldots,dims$

$output(k_1,\ldots,k_{dims})$ is defined if $1 \le k_n \le zshape(n)$ for every $n=1,\ldots,dims$.

Relation between the input vectors and the functions *u* and *v* is defined by the following formulas:

$inputu(i_1,\ldots,i_{dims}) = u(p_1,\ldots,p_N)$, where $p_n = P_n^{min} + (i_n-1)$ for every n

$inputv(j_1,\ldots,j_{dims}) = v(q_1,\ldots,q_N)$, where $q_n=Q_n^{min} + (j_n-1)$ for every n.

The relation between the output vector and the function *w(r)* is similar (but only in the case when parameters *start* and *decimation* are not defined):

$output(k_1,\ldots,k_{dims}) = w(r_1,\ldots,r_N)$, where $r_n=R_n^{min} + (k_n-1)$ for every n.

If the parameter *start* is defined, it must belong to the interval $R_n^{min} \le start(n) \le R_n^{max}$. If defined, the *start* parameter replaces R^{min} in the formula:

$output(k_1,\ldots,k_{dims})=w(r_1,\ldots,r_N)$, where $r_n=start(n) + (k_n-1)$

If the parameter *decimation* is defined, it changes the relation according to the following formula:

$output(k_1,\ldots,k_{dims})=w(r_1,\ldots,r_N)$, where $r_n= R_n^{min} + (k_n-1)*decimation(n)$

If both parameters *start* and *decimation* are defined, the formula is as follows:

output(k_1,...,k_{dims})=w(r_1,...,r_N), where r_n=start(n) + (k_n-1)*decimation(n)

The convolution and correlation software checks the values of *zshape*, *start*, and *decimation* during task commitment. If r_n exceeds R_n^{max} for some k_n,n=1,...,dims, an error is raised.

Allocation of Data Vectors

Both parameter arrays *x* and *y* contain input data vectors in memory, while array *z* is intended for storing output data vector. To access the memory, the convolution and correlation software uses only pointers to these arrays and ignores the array shapes.

For parameters *x*, *y*, and *z*, you can provide one-dimensional arrays with the requirement that actual length of these arrays be sufficient to store the data vectors.

The allocation of the input and output data inside the arrays *x*, *y*, and *z* is described below assuming that the arrays are one-dimensional. Given multi-dimensional indices $i, j, k \in \mathbf{Z}^N$, one-dimensional indices $e, f, g \in \mathbf{Z}$ are defined such that:

inputu(i_1,...,i_{dims}) is allocated at *x(e)*

inputv(j_1,...,j_{dims}) is allocated at *y(f)*

output(k_1,...,k_{dims}) is allocated at *z(g)*.

The indices *e*, *f*, and *g* are defined as follows:

$e = 1 + \sum xstride(n) \cdot dx(n)$ (the sum is for all n=1,...,dims)

$f = 1 + \sum ystride(n) \cdot dy(n)$ (the sum is for all n=1,...,dims)

$g = 1 + \sum zstride(n) \cdot dz(n)$ (the sum is for all n=1,...,dims)

The distances dx(n), dy(n), and dz(n) depend on the signum of the stride:

dx(n) = i_n-1 if xstride(n)>0, or dx(n) = i_n-xshape(n) if xstride(n)<0

dy(n) = j_n-1 if ystride(n)>0, or dy(n) = j_n-yshape(n) if ystride(n)<0

dz(n) = k_n-1 if zstride(n)>0, or dz(n) = k_n-zshape(n) if zstride(n)<0

The definitions of indices *e*, *f*, and *g* assume that indexes for arrays *x*, *y*, and *z* are started from unity:

x(e) is defined for e=1,...,length(x)

y(f) is defined for f=1,...,length(y)

z(g) is defined for g=1,...,length(z)

Below is a detailed explanation about how elements of the multi-dimensional output vector are stored in the array *z* for one-dimensional and two-dimensional cases.

One-dimensional case. If *dims*=1, then *zshape* is the number of the output values to be stored in the array *z*. The actual length of array *z* may be greater than *zshape* elements.

If zstride>1, output values are stored with the stride: output(1) is stored to z(1), output(2) is stored to z(1+zstride), and so on. Hence, the actual length of *z* must be at least 1+zstride*(zshape-1) elements or more.

If zstride<0, it still defines the stride between elements of array *z*. However, the order of the used elements is the opposite. For the *k*-th output value, output(k) is stored in z(1+|zstride|*(zshape-k)), where |zstride| is the absolute value of zstride. The actual length of the array *z* must be at least 1+|zstride| *(zshape - 1) elements.

Two-dimensional case. If *dims*=2, the output data is a two-dimensional matrix. The value zstride(1) defines the stride inside matrix columns, that is, the stride between the output(k_1, k_2) and output(k_1+1, k_2) for every pair of indices k_1, k_2. On the other hand, zstride(2) defines the stride between columns, that is, the stride between output(k_1,k_2) and output(k_1,k_2+1).

If zstride(2) is greater than zshape(1), this causes sparse allocation of columns. If the value of zstride(2) is smaller than zshape(1), this may result in the transposition of the output matrix. For example, if zshape = (2,3), you can define zstride = (3,1) to allocate output values like transposed matrix of the shape 3x2.

Whether zstride assumes this kind of transformations or not, you need to ensure that different elements output (k_1, ...,k_{dims}) will be stored in different locations *z(g)*.

Summary Statistics

The Summary Statistics domain provides routines that compute basic statistical estimates for single and double precision multi-dimensional datasets.

The Summary Statistics routines calculate:

- raw and central moments up to the fourth order
- skewness and excess kurtosis (further referred to as *kurtosis* for brevity)
- variation coefficient
- quantiles and order statistics
- minimum and maximum
- variance-covariance/correlation matrix
- pooled/group variance-covariance matrix and mean
- partial variance-covariance/correlation matrix
- robust estimators for variance-covariance matrix and mean in presence of outliers
- raw/central partial sums up to the fourth order (for brevity referred to as *raw/central sums*)
- matrix of cross-products and sums of squares (for brevity referred to as *cross-product matrix*)
- median absolute deviation, mean absolute deviation

The library also contains functions to perform the following tasks:

- Detect outliers in datasets
- Support missing values in datasets
- Parameterize correlation matrices
- Compute quantiles for streaming data

Mathematical Notation and Definitions defines the supported operations in the Summary Statistics routines.

You can access the Summary Statistics routines through the Fortran 90 and C89 language interfaces. You can use the Fortran 90 interface with programs written in Fortran 95.

The mkl_vsl.f90 header file is in the ${MKL}/include directory.

See more details about the Fortran header in Random Number Generators topic.

You can find examples that demonstrate calculation of the Summary Statistics estimates in the ${MKL}/examples/vslf example directory.

The Summary Statistics API is implemented through task objects, or tasks. A task object is a data structure, or a descriptor, holding parameters that determine a specific Summary Statistics operation. For example, such parameters may be precision, dimensions of user data, the matrix of the observations, or shapes of data arrays.

All the Summary Statistics routines process a task object as follows:

1. Create a task.
2. Modify settings of the task parameters.
3. Compute statistical estimates.
4. Destroy the task.

The Summary Statistics functions fall into the following categories:

Task Constructors - routines that create a new task object descriptor and set up most common parameters (dimension, number of observations, and matrix of the observations).

Task Editors - routines that can set or modify some parameter settings in the existing task descriptor.

Task Computation Routine - a routine that computes specified statistical estimates.

Task Destructor - a routine that deletes the task object and frees the memory.

A Summary Statistics task object contains a series of pointers to the input and output data arrays. You can read and modify the datasets and estimates at any time but you should allocate and release memory for such data.

See detailed information on the algorithms, API, and their usage in the *Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes* [SS Notes].

Summary Statistics Naming Conventions

The names of routines in the Summary Statistics are in lowercase (`vslsssseditquantiles`), while the names of types and constants are in uppercase. The names are not case-sensitive.

The names of routines have the following structure:

`vsl[datatype]ss<base name>`

where

- `vsl`is a prefix indicating that the routine belongs to Intel® oneAPI Math Kernel Library (oneMKL) Vector Statistics.
- `[datatype]` specifies the type of the input and/or output data and can be `s` (single precision real type), `d` (double precision real type), or `i` (integer type).
- `SS`/`ss` indicates that the routine is intended for calculations of the Summary Statistics estimates.
- *<base name>* specifies a particular functionality that the routine is designed for, for example, `NewTask`, `Compute`, `DeleteTask`.

NOTE
The Summary Statistics routine `vslDeleteTask` for deletion of the task is independent of the data type and its name omits the `[datatype]` field.

Summary Statistics Data Types

The Summary Statistics routines use the following data types for calculations:

Type	Data Object
Fortran 90: `TYPE(VSL_SS_TASK)`	Pointer to a Summary Statistics task
Fortran 90: `REAL(KIND=4)`	Input/output user data in single precision
Fortran 90: `REAL(KIND=8)`	Input/output user data in double precision
Fortran 90: `INTEGER` or `INTEGER(KIND=8)`	Other data

NOTE
The actual size of the generic integer type is platform-specific and can be 32 or 64 bits in length. Before you compile your application, set an appropriate size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*.

Summary Statistics Parameters

The basic parameters in the task descriptor (addresses of dimensions, number of observations, and datasets) are assigned values when the task editors create or modify the task object. Other parameters are determined by the specific task and changed by the task editors.

Summary Statistics Task Status and Error Reporting

The task status is an integer value, which is zero if no error is detected, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The header files define symbolic names for the status codes. These names are defined as integer constants via `PARAMETER` operators.

The header files define the following status codes for the Summary Statistics error codes:

Summary Statistics Status Codes

Status Code	Description
`VSL_STATUS_OK`	Operation is successfully completed.
`VSL_SS_ERROR_ALLOCATION_FAILURE`	Memory allocation has failed.
`VSL_SS_ERROR_BAD_DIMEN`	Dimension value is invalid.
`VSL_SS_ERROR_BAD_OBSERV_N`	Invalid number (zero or negative) of observations was obtained.
`VSL_SS_ERROR_STORAGE_NOT_SUPPORTED`	Storage format is not supported.
`VSL_SS_ERROR_BAD_INDC_ADDR`	Array of indices is not defined.
`VSL_SS_ERROR_BAD_WEIGHTS`	Array of weights contains negative values.
`VSL_SS_ERROR_BAD_MEAN_ADDR`	Array of means is not defined.
`VSL_SS_ERROR_BAD_2R_MOM_ADDR`	Array of the second order raw moments is not defined.
`VSL_SS_ERROR_BAD_3R_MOM_ADDR`	Array of the third order raw moments is not defined.
`VSL_SS_ERROR_BAD_4R_MOM_ADDR`	Array of the fourth order raw moments is not defined.
`VSL_SS_ERROR_BAD_2C_MOM_ADDR`	Array of the second order central moments is not defined.
`VSL_SS_ERROR_BAD_3C_MOM_ADDR`	Array of the third order central moments is not defined.
`VSL_SS_ERROR_BAD_4C_MOM_ADDR`	Array of the fourth order central moments is not defined.
`VSL_SS_ERROR_BAD_KURTOSIS_ADDR`	Array of kurtosis values is not defined.
`VSL_SS_ERROR_BAD_SKEWNESS_ADDR`	Array of skewness values is not defined.
`VSL_SS_ERROR_BAD_MIN_ADDR`	Array of minimum values is not defined.
`VSL_SS_ERROR_BAD_MAX_ADDR`	Array of maximum values is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_VARIATION_ADDR	Array of variation coefficients is not defined.
VSL_SS_ERROR_BAD_COV_ADDR	Covariance matrix is not defined.
VSL_SS_ERROR_BAD_COR_ADDR	Correlation matrix is not defined.
VSL_SS_ERROR_BAD_QUANT_ORDER_ADDR	Array of quantile orders is not defined.
VSL_SS_ERROR_BAD_QUANT_ORDER	Quantile order value is invalid.
VSL_SS_ERROR_BAD_QUANT_ADDR	Array of quantiles is not defined.
VSL_SS_ERROR_BAD_ORDER_STATS_ADDR	Array of order statistics is not defined.
VSL_SS_ERROR_MOMORDER_NOT_SUPPORTED	Moment of requested order is not supported.
VSL_SS_NOT_FULL_RANK_MATRIX	Correlation matrix is not of full rank.
VSL_SS_ERROR_ALL_OBSERVS_OUTLIERS	All observations are outliers. (At least one observation must not be an outlier.)
VSL_SS_ERROR_BAD_ROBUST_COV_ADDR	Robust covariance matrix is not defined.
VSL_SS_ERROR_BAD_ROBUST_MEAN_ADDR	Array of robust means is not defined.
VSL_SS_ERROR_METHOD_NOT_SUPPORTED	Requested method is not supported.
VSL_SS_ERROR_NULL_TASK_DESCRIPTOR	Task descriptor is null.
VSL_SS_ERROR_BAD_OBSERV_ADDR	Dataset matrix is not defined.
VSL_SS_ERROR_BAD_ACCUM_WEIGHT_ADDR	Pointer to the variable that holds the value of accumulated weight is not defined.
VSL_SS_ERROR_SINGULAR_COV	Covariance matrix is singular.
VSL_SS_ERROR_BAD_POOLED_COV_ADDR	Pooled covariance matrix is not defined.
VSL_SS_ERROR_BAD_POOLED_MEAN_ADDR	Array of pooled means is not defined.
VSL_SS_ERROR_BAD_GROUP_COV_ADDR	Group covariance matrix is not defined.
VSL_SS_ERROR_BAD_GROUP_MEAN_ADDR	Array of group means is not defined.
VSL_SS_ERROR_BAD_GROUP_INDC_ADDR	Array of group indices is not defined.
VSL_SS_ERROR_BAD_GROUP_INDC	Group indices have improper values.
VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_ADDR	Array of parameters for the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_N_ADDR	Pointer to size of the parameter array for the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_OUTLIERS_WEIGHTS_ADDR	Output of the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_ADDR	Array of parameters of the robust covariance estimation algorithm is not defined.
VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_N_ADDR	Pointer to the number of parameters of the algorithm for robust covariance is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_STORAGE_ADDR	Pointer to the variable that holds the storage format is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COV_IDX_ADDR	Array that encodes sub-components of a random vector for the partial covariance algorithm is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COV_IDX	Array that encodes sub-components of a random vector for partial covariance has improper values.
VSL_SS_ERROR_BAD_PARTIAL_COV_ADDR	Partial covariance matrix is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COR_ADDR	Partial correlation matrix is not defined.
VSL_SS_ERROR_BAD_MI_PARAMS_ADDR	Array of parameters for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_PARAMS_N_ADDR	Pointer to number of parameters for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_BAD_PARAMS_N	Size of the parameter array of the Multiple Imputation method is invalid.
VSL_SS_ERROR_BAD_MI_PARAMS	Parameters of the Multiple Imputation method are invalid.
VSL_SS_ERROR_BAD_MI_INIT_ESTIMATES_N_ADDR	Pointer to the number of initial estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_INIT_ESTIMATES_ADDR	Array of initial estimates for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_ADDR	Array of simulated missing values in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_N_ADDR	Pointer to the size of the array of simulated missing values in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_ESTIMATES_N_ADDR	Pointer to the number of parameter estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_ESTIMATES_ADDR	Array of parameter estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_N	Invalid size of the array of simulated values in the Multiple Imputation method.
VSL_SS_ERROR_BAD_MI_ESTIMATES_N	Invalid size of an array to hold parameter estimates obtained using the Multiple Imputation method.
VSL_SS_ERROR_BAD_MI_OUTPUT_PARAMS	Array of output parameters in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_PRIOR_N_ADDR	Pointer to the number of prior parameters is not defined.
VSL_SS_ERROR_BAD_MI_PRIOR_ADDR	Array of prior parameters is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_MI_MISSING_VALS_N	Invalid number of missing values was obtained.
VSL_SS_SEMIDEFINITE_COR	Correlation matrix passed into the parameterization function is semi-definite.
VSL_SS_ERROR_BAD_PARAMTR_COR_ADDR	Correlation matrix to be parameterized is not defined.
VSL_SS_ERROR_BAD_COR	All eigenvalues of the correlation matrix to be parameterized are non-positive.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_N_ADDR	Pointer to the number of parameters for the quantile computation algorithm for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_ADDR	Array of parameters of the quantile computation algorithm for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_N	Invalid number of parameters of the quantile computation algorithm for streaming data has been obtained.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS	Invalid parameters of the quantile computation algorithm for streaming data have been passed.
VSL_SS_ERROR_BAD_STREAM_QUANT_ORDER_ADDR	Array of the quantile orders for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_ORDER	Invalid quantile order for streaming data is defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_ADDR	Array of quantiles for streaming data is not defined.
VSL_SS_ERROR_BAD_SUM_ADDR	Array of sums is not defined.
VSL_SS_ERROR_BAD_2R_SUM_ADDR	Array of raw sums of 2nd order is not defined.
VSL_SS_ERROR_BAD_3R_SUM_ADDR	Array of raw sums of 3rd order is not defined.
VSL_SS_ERROR_BAD_4R_SUM_ADDR	Array of raw sums of 4th order is not defined.
VSL_SS_ERROR_BAD_2C_SUM_ADDR	Array of central sums of 2nd order is not defined.
VSL_SS_ERROR_BAD_3C_SUM_ADDR	Array of central sums of 3rd order is not defined.
VSL_SS_ERROR_BAD_4C_SUM_ADDR	Array of central sums of 4th order is not defined.
VSL_SS_ERROR_BAD_CP_SUM_ADDR	Cross-product matrix is not defined.
VSL_SS_ERROR_BAD_MDAD_ADDR	Array of median absolute deviations is not defined.
VSL_SS_ERROR_BAD_MNAD_ADDR	Array of mean absolute deviations is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_SORTED_OBSERV_ADDR	Array for storing observation sorting results is not defined.
VSL_SS_ERROR_ERROR_INDICES_NOT_SUPPORTED	Array of indices is not supported.

Routines for robust covariance estimation, outlier detection, partial covariance estimation, multiple imputation, and parameterization of a correlation matrix can return internal error codes that are related to a specific implementation. Such error codes indicate invalid input data or other bugs in the Intel® oneAPI Math Kernel Library (oneMKL) routines other than the Summary Statistics routines.

Summary Statistics Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters.

NOTE
If the constructor fails to create a task descriptor, it returns the NULL task pointer.

vslSSNewTask

Creates and initializes a new summary statistics task descriptor.

Syntax

status = vslsssnewtask(*task*, *p*, *n*, *xstorage*, *x*, *w*, *indices*)

status = vsldssnewtask(*task*, *p*, *n*, *xstorage*, *x*, *w*, *indices*)

Include Files

- mkl_vsl.f90

Input Parameters

Name	Type	Description
p	INTEGER	Dimension of the task, number of variables
n	INTEGER	Number of observations
xstorage	INTEGER	Storage format of matrix of observations
x	REAL(KIND=4) DIMENSION(*) for vslsssnewtask REAL(KIND=8) DIMENSION(*) for vsldssnewtask	Matrix of observations
w	REAL(KIND=4) DIMENSION(*) for vslsssnewtask REAL(KIND=8) DIMENSION(*) for vsldssnewtask	Array of weights of size *n*. Elements of the arrays are non-negative numbers. If a NULL pointer is passed, each observation is assigned weight equal to 1.

Name	Type	Description
indices	INTEGER, DIMENSION(*)	Array of vector components that will be processed. Size of array is p. If a NULL pointer is passed, all components of random vector are processed.

Output Parameters

Name	Type	Description
task	TYPE(VSL_SS_TASK)	Descriptor of the task
status	INTEGER	Set to VSL_STATUS_OK if the task is created successfully, otherwise a non-zero error code is returned.

Description

Each vslSSNewTask constructor routine creates a new summary statistics task descriptor with the user-specified value for a required parameter, dimension of the task. The optional parameters (matrix of observations, its storage format, number of observations, weights of observations, and indices of the random vector components) are set to their default values.

The observations of random p-dimensional vector $\xi = (\xi_1, ..., \xi_i, ..., \xi_p)$, which are n vectors of dimension p, are passed as a one-dimensional array x. The parameter *xstorage* defines the storage format of the observations and takes one of the possible values listed in Table "Storage format of matrix of observations and order statistics".

Storage format of matrix of observations, order statistics, and matrix of sorted observations

Parameter	Description
VSL_SS_MATRIX_STORAGE_ROWS	The observations of random vector ξ are packed by rows: n data points for the vector component ξ_1 come first, n data points for the vector component ξ_2 come second, and so forth.
VSL_SS_MATRIX_STORAGE_COLS	The observations of random vector ξ are packed by columns: the first p-dimensional observation of the vector ξ comes first, the second p-dimensional observation of the vector comes second, and so forth.

NOTE
Since matrices in Fortran are stored by columns while in C they are stored by rows, initialization of the *xstorage* variable in Fortran is opposite to that in C. Set *xstorage* to VSL_SS_MATRIX_STORAGE_COLS, if the dataset is stored as a two-dimensional matrix that consists of p rows and n columns; otherwise, use the VSL_SS_MATRIX_STORAGE_ROWS constant.

A one-dimensional array w of size n contains non-negative weights assigned to the observations. You can pass a NULL array into the constructor. In this case, each observation is assigned the default value of the weight.

You can choose vector components for which you wish to compute statistical estimates. If an element of the vector indices of size p contains 0, the observations that correspond to this component are excluded from the calculations. If you pass the `NULL` value of the parameter into the constructor, statistical estimates for all random variables are computed.

If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

Summary Statistics Task Editors

Task editors are intended to set up or change the task parameters listed in Table "Parameters of Summary Statistics Task to Be Initialized or Modified". As an example, to compute the sample mean for a one-dimensional dataset, initialize a variable for the mean value, and pass its address into the task as shown in the example below:

```
#define DIM    1
#define N   1000

int main()
{
     VSLSSTaskPtr task;
     double x[N];
     double mean;
     MKL_INT p, n, xstorage;
     int status;
     /* initialize variables used in the computations of sample mean */
     p = DIM;
     n = N;
     xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
     mean = 0.0;

     /* create task */
     status = vsldSSNewTask( &task, &p, &n, &xstorage, x, 0, 0 );

     /* initialize task parameters */
     status = vsldSSEditTask( task, VSL_SS_ED_MEAN, &mean );

     /* compute mean using SS fast method */
     status = vsldSSCompute(task, VSL_SS_MEAN, VSL_SS_METHOD_FAST );

     /* deallocate task resources */
     status = vslSSDeleteTask( &task );

     return 0;
}
```

Use the single (`vslsssedittask`) or double (`vsldsseditask`) version of an editor, to initialize single or double precision version task parameters, respectively. Use an integer version of an editor (`vslisseditask`) to initialize parameters of the integer type.

Table "Summary Statistics Task Editors" lists the task editors for Summary Statistics. Each of them initializes and/or modifies a respective group of related parameters.

Summary Statistics Task Editors

Editor	Description
`vslSSEditTask`	Changes a pointer in the task descriptor.
`vslSSEditMoments`	Changes pointers to arrays associated with raw and central moments.

Editor	Description
vslSSEditSums	Modifies the pointers to arrays that hold sum estimates.
vslSSEditCovCor	Changes pointers to arrays associated with covariance and/or correlation matrices.
vslSSEditCP	Modifies the pointers to cross-product matrix parameters.
vslSSEditPartialCovCor	Changes pointers to arrays associated with partial covariance and/or correlation matrices.
vslSSEditQuantiles	Changes pointers to arrays associated with quantile/order statistics calculations.
vslSSEditStreamQuantiles	Changes pointers to arrays for quantile related calculations for streaming data.
vslSSEditPooledCovariance	Changes pointers to arrays associated with algorithms related to a pooled covariance matrix.
vslSSEditRobustCovariance	Changes pointers to arrays for robust estimation of a covariance matrix and mean.
vslSSEditOutliersDetection	Changes pointers to arrays for detection of outliers.
vslSSEditMissingValues	Changes pointers to arrays associated with the method of supporting missing values in a dataset.
vslSSEditCorParameterization	Changes pointers to arrays associated with the algorithm for parameterization of a correlation matrix.

NOTE
You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

vslSSEditTask

Modifies address of an input/output parameter in the task descriptor.

Syntax

```
status = vslsssedittask(task, parameter, par_addr)
status = vsldssedittask(task, parameter, par_addr)
status = vslissedittask(task, parameter, par_addr)
```

Include Files

- `mkl_vsl.f90`

Input Parameters

Name	Type	Description
task	`TYPE(VSL_SS_TASK)`	Descriptor of the task
parameter	`INTEGER`	Parameter to change

Name	Type	Description

par_addr	`REAL(KIND=4) DIMENSION(*)` for `vslsssedittask`
	`REAL(KIND=8) DIMENSION(*)` for `vsldssedittask`
	`INTEGER DIMENSION(*)` for `vslissedittask`
		Address of the new parameter

Output Parameters

Name	Type	Description
status	`INTEGER`	Current status of the task

Description

The `vslSSEditTask` routine replaces the pointer to the parameter stored in the Summary Statistics task descriptor with the *par_addr* pointer. If you pass the `NULL` pointer to the editor, no changes take place in the task and a corresponding error code is returned. See Table "Parameters of Summary Statistics Task to Be Initialized or Modified" for the predefined values of the parameter.

Use the single (`vslsssedittask`) or double (`vsldssedittask`) version of the editor, to initialize single or double precision version task parameters, respectively. Use an integer version of the editor (`vslissedittask`) to initialize parameters of the integer type.

Parameters of Summary Statistics Task to Be Initialized or Modified

Parameter Value	Type	Purpose	Initialization
`VSL_SS_ED_DIMEN`	`i`	Address of a variable that holds the task dimension	Required. Positive integer value.
`VSL_SS_ED_OBSERV_N`	`i`	Address of a variable that holds the number of observations	Required. Positive integer value.
`VSL_SS_ED_OBSERV`	`d`, `s`	Address of the observation matrix	Required. Provide the matrix containing your observations.
`VSL_SS_ED_OBSERV_STORAGE`	`i`	Address of a variable that holds the storage format for the observation matrix	Required. Provide a storage format supported by the library whenever you pass a matrix of observations.[1]
`VSL_SS_ED_INDC`	`i`	Address of the array of indices	Optional. Provide this array if you need to process individual components of the random vector. Set entry *i* of the array to one to include the *i*th coordinate in the analysis. Set entry *i* of the array to zero to exclude the *i*th coordinate from the analysis.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_WEIGHTS	d, s	Address of the array of observation weights	Optional. If the observations have weights different from the default weight (one), set entries of the array to non-negative floating point values.
VSL_SS_ED_MEAN	d, s	Address of the array of means	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2R_MOM	d, s	Address of an array of raw moments of the second order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3R_MOM	d, s	Address of an array of raw moments of the third order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_4R_MOM	d, s	Address of an array of raw moments of the fourth order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2C_MOM	d, s	Address of an array of central moments of the second order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.
VSL_SS_ED_3C_MOM	d, s	Address of an array of central moments of the third order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.
VSL_SS_ED_4C_MOM	d, s	Address of an array of central moments of the fourth order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make

Parameter Value	Type	Purpose	Initialization
			sure you also provide arrays for raw moments of the first, second, third, and fourth order.
VSL_SS_ED_KURTOSIS	d, s	Address of the array of kurtosis estimates	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, third, and fourth order.
VSL_SS_ED_SKEWNESS	d, s	Address of the array of skewness estimates	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.
VSL_SS_ED_MIN	d, s	Address of the array of minimum estimates	Optional. Set entries of array to meaningful values, such as the values of the first observation.
VSL_SS_ED_MAX	d, s	Address of the array of maximum estimates	Optional. Set entries of array to meaningful values, such as the values of the first observation.
VSL_SS_ED_VARIATION	d, s	Address of the array of variation coefficients	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.
VSL_SS_ED_COV	d, s	Address of a covariance matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Make sure you also provide an array for the mean.
VSL_SS_ED_COV_STORAGE	i	Address of the variable that holds the storage format for a covariance matrix	Required. Provide a storage format supported by the library whenever you intend to compute the covariance matrix.[2]
VSL_SS_ED_COR	d, s	Address of a correlation matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a

Parameter Value	Type	Purpose	Initialization
			progressive estimate. If you initialize the matrix in non-trivial way, make sure that the main diagonal contains variance values. Also, provide an array for the mean.
VSL_SS_ED_COR_STORAGE	i	Address of the variable that holds the correlation storage format for a correlation matrix	Required. Provide a storage format supported by the library whenever you intend to compute the correlation matrix.[2]
VSL_SS_ED_ACCUM_WEIGHT	d, s	Address of the array of size 2 that holds the accumulated weight (sum of weights) in the first position and the sum of weights squared in the second position	Optional. Set the entries of the matrix to meaningful values (typically zero) if you intend to do progressive processing of the dataset or need the sum of weights and sum of squared weights assigned to observations.
VSL_SS_ED_QUANT_ORDER_N	i	Address of the variable that holds the number of quantile orders	Required. Positive integer value. Provide the number of quantile orders whenever you compute quantiles.
VSL_SS_ED_QUANT_ORDER	d, s	Address of the array of quantile orders	Required. Set entries of array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.
VSL_SS_ED_QUANT_QUANTILES	d, s	Address of the array of quantiles	None.
VSL_SS_ED_ORDER_STATS	d, s	Address of the array of order statistics	None.
VSL_SS_ED_GROUP_INDC	i	Address of the array of group indices used in computation of a pooled covariance matrix	Required. Set entry *i* to integer value *k* if the observation belongs to group *k*. Values of *k* take values in the range [0, *g*-1], where *g* is the number of groups.
VSL_SS_ED_POOLED_COV_STORAGE	i	Address of a variable that holds the storage format for a pooled covariance matrix	Required. Provide a storage format supported by the library whenever you intend to compute pooled covariance.[2]
VSL_SS_ED_POOLED_MEAN	d, s	Address of an array of pooled means	None.
VSL_SS_ED_POOLED_COV	d, s	Address of pooled covariance matrices	None.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_GROUP_COV_INDC	i	Address of an array of indices for which covariance/means should be computed	Optional. Set the *k*th entry of the array to 1 if you need group covariance and mean for group *k*; otherwise set it to zero.
VSL_SS_ED_REQ_GROUP_INDC	i	Address of an array of indices for which group estimates such as covariance or means are requested	Optional. Set the *k*th entry of the array to 1 if you need an estimate for group *k*; otherwise set it to zero.
VSL_SS_ED_GROUP_MEANS	i	Address of an array of group means	None.
VSL_SS_ED_GROUP_COV_STORAGE	d, s	Address of a variable that holds the storage format for a group covariance matrix	Required. Provide a storage format supported by the library whenever you intend to get group covariance.[2]
VSL_SS_ED_GROUP_COV	d, s	Address of group covariance matrices	None.
VSL_SS_ED_ROBUST_COV_STORAGE	d, s	Address of a variable that holds the storage format for a robust covariance matrix	Required. Provide a storage format supported by the library whenever you compute robust covariance[2].
VSL_SS_ED_ROBUST_COV_PARAMS_N	i	Address of a variable that holds the number of algorithmic parameters of the method for robust covariance estimation	Required. Set to the number of TBS parameters, *VSL_SS_TBS_PARAMS_N*.
VSL_SS_ED_ROBUST_COV_PARAMS	d, s	Address of an array of parameters of the method for robust estimation of a covariance	Required. Set the entries of the array according to the description in vslSSEditRobustCovariance.
VSL_SS_ED_ROBUST_MEAN	i	Address of an array of robust means	None.
VSL_SS_ED_ROBUST_COV	d, s	Address of a robust covariance matrix	None.
VSL_SS_ED_OUTLIERS_PARAMS_N	d, s	Address of a variable that holds the number of parameters of the outlier detection method	Required. Set to the number of outlier detection parameters, *VSL_SS_BACON_PARAMS_N*.
VSL_SS_ED_OUTLIERS_PARAMS	i	Address of an array of algorithmic parameters for the outlier detection method	Required. Set the entries of the array according to the description in vslSSEditOutliersDetection.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_OUTLIERS_WEIGHT	d, s	Address of an array of weights assigned to observations by the outlier detection method	None.
VSL_SS_ED_ORDER_STATS_STORAGE	d, s	Address of a variable that holds the storage format of an order statistics matrix	Required. Provide a storage format supported by the library whenever you compute a matrix of order statistics.[1]
VSL_SS_ED_PARTIAL_COV_IDX	i	Address of an array that encodes subcomponents of a random vector	Required. Set the entries of the array according to the description in vslSSEditPartialCovCor.
VSL_SS_ED_PARTIAL_COV	d, s	Address of a partial covariance matrix	None.
VSL_SS_ED_PARTIAL_COV_STORAGE	i	Address of a variable that holds the storage format of a partial covariance matrix	Required. Provide a storage format supported by the library whenever you compute the partial covariance.[2]
VSL_SS_ED_PARTIAL_COR	d, s	Address of a partial correlation matrix	None.
VSL_SS_ED_PARTIAL_COR_STORAGE	i	Address of a variable that holds the storage format for a partial correlation matrix	Required. Provide a storage format supported by the library whenever you compute the partial correlation.[2]
VSL_SS_ED_MI_PARAMS_N	i	Address of a variable that holds the number of algorithmic parameters for the Multiple Imputation method	Required. Set to the number of MI parameters, *VSL_SS_MI_PARAMS_SIZE*.
VSL_SS_ED_MI_PARAMS	d, s	Address of an array of algorithmic parameters for the Multiple Imputation method	Required. Set entries of the array according to the description in vslSSEditMissingValues.
VSL_SS_ED_MI_INIT_ESTIMATES_N	i	Address of a variable that holds the number of initial estimates for the Multiple Imputation method	Optional. Set to $p+p*(p+1)/2$, where p is the task dimension.
VSL_SS_ED_MI_INIT_ESTIMATES	d, s	Address of an array of initial estimates for the Multiple Imputation method	Optional. Set the values of the array according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics" in the *Intel® oneAPI Math Kernel Library*

Parameter Value	Type	Purpose	Initialization
			(oneMKL) Summary Statistics Application Notes document [SS Notes].
VSL_SS_ED_MI_SIMUL_VALS_N	i	Address of a variable that holds the number of simulated values in the Multiple Imputation method	Optional. Positive integer indicating the number of missing points in the observation matrix.
VSL_SS_ED_MI_SIMUL_VALS	d, s	Address of an array of simulated values in the Multiple Imputation method	None.
VSL_SS_ED_MI_ESTIMATES_N	i	Address of a variable that holds the number of estimates obtained as a result of the Multiple Imputation method	Optional. Positive integer number defined according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics" in the *Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes* document [SS Notes].
VSL_SS_ED_MI_ESTIMATES	d, s	Address of an array of estimates obtained as a result of the Multiple Imputation method	None.
VSL_SS_ED_MI_PRIOR_N	i	Address of a variable that holds the number of prior parameters for the Multiple Imputation method	Optional. If you pass a user-defined array of prior parameters, set this parameter to $(p^2+3*p+4)/2$, where p is the task dimension.
VSL_SS_ED_MI_PRIOR	d, s	Address of an array of prior parameters for the Multiple Imputation method	Optional. Set entries of the array of prior parameters according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics" in the *Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes* document [SS Notes].
VSL_SS_ED_PARAMTR_COR	d, s	Address of a parameterized correlation matrix	None.
VSL_SS_ED_PARAMTR_COR_STORAGE	i	Address of a variable that holds the storage format of a parameterized correlation matrix	Required. Provide a storage format supported by the library whenever you compute the parameterized correlation matrix.[2]

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_STREAM_QUANT_PARAMS_N	i	Address of a variable that holds the number of parameters of a quantile computation method for streaming data	Required. Set to the number of quantile computation parameters, *VSL_SS_SQUANTS_ZW_PARAMS_N*.
VSL_SS_ED_STREAM_QUANT_PARAMS	d, s	Address of an array of parameters of a quantile computation method for streaming data	Required. Set the entries of the array according to the description in "Computing Quantiles for Streaming Data" in the *Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes* document [SS Notes].
VSL_SS_ED_STREAM_QUANT_ORDER_N	i	Address of a variable that holds the number of quantile orders for streaming data	Required. Positive integer value.
VSL_SS_ED_STREAM_QUANT_ORDER	d, s	Address of an array of quantile orders for streaming data	Required. Set entries of the array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.
VSL_SS_ED_STREAM_QUANT_QUANTILES	d, s	Address of an array of quantiles for streaming data	None.
VSL_SS_ED_SUM	d, s	Address of array of sums	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2R_SUM	d, s	Address of array of raw sums of 2nd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3R_SUM	d, s	Address of array of raw sums of 3rd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_4R_SUM	d, s	Address of array of raw sums of 4th order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_2C_SUM	d, s	Address of array of central sums of 2nd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3C_SUM	d, s	Address of array of central sums of 3rd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_4C_SUM	d, s	Address of array of central sums of 4th order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_CP	d, s	Address of cross-product matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_MDAD	d, s	Address of array of median absolute deviations	None.
VSL_SS_ED_MNAD	d, s	Address of array of mean absolute deviations	None.
VSL_SS_ED_SORTED_OBSERV	d, s	Address of the array that stores sorted results	None.
VSL_SS_ED_SORTED_OBSERV_STORAGE	i	Address of a variable that holds the storage format of an output matrix	Required. Provide a supported storage format whenever you specify sorting of the observation matrix.

1. See Table: "Storage format of matrix of observations and order statistics" for storage formats.
2. See Table: "Storage formats of a variance-covariance/correlation matrix" for storage formats.

vslSSEditMoments

Modifies the pointers to arrays that hold moment estimates.

Syntax

```
status = vslssseditmoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m)
status = vsldsseditmoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m)
```

Include Files

- mkl_vsl.f90

Input Parameters

Name	Type	Description
task	TYPE(VSL_SS_TASK)	Descriptor of the task
mean	REAL(KIND=4) DIMENSION(*) for vslssseditmoments REAL(KIND=8) DIMENSION(*) for vsldsseditmoments	Pointer to the array of means
r2m	REAL(KIND=4) DIMENSION(*) for vslssseditmoments REAL(KIND=8) DIMENSION(*) for vsldsseditmoments	Pointer to the array of raw moments of the 2nd order
r3m	REAL(KIND=4) DIMENSION(*) for vslssseditmoments REAL(KIND=8) DIMENSION(*) for vsldsseditmoments	Pointer to the array of raw moments of the 3rd order
r4m	REAL(KIND=4) DIMENSION(*) for vslssseditmoments REAL(KIND=8) DIMENSION(*) for vsldsseditmoments	Pointer to the array of raw moments of the 4th order
c2m	REAL(KIND=4) DIMENSION(*) for vslssseditmoments REAL(KIND=8) DIMENSION(*) for vsldsseditmoments	Pointer to the array of central moments of the 2nd order
c3m	REAL(KIND=4) DIMENSION(*) for vslssseditmoments REAL(KIND=8) DIMENSION(*) for vsldsseditmoments	Pointer to the array of central moments of the 3rd order
c4m	REAL(KIND=4) DIMENSION(*) for vslssseditmoments REAL(KIND=8) DIMENSION(*) for vsldsseditmoments	Pointer to the array of central moments of the 4th order

Output Parameters

Name	Type	Description
status	INTEGER	Current status of the task

Description

The vslSSEditMoments routine replaces pointers to the arrays that hold estimates of raw and central moments with values passed as corresponding parameters of the routine. If you pass a value of NULL for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

vslSSEditSums

Modifies the pointers to arrays that hold sum estimates.

Syntax

```
status = vslssseditsums(task, sum, r2s, r3s, r4s, c2s, c3s, c4s)
status = vsldsseditsums(task, sum, r2s, r3s, r4s, c2s, c3s, c4s)
```

Include Files

- mkl_vsl.f90

Input Parameters

Name	Type	Description
task	TYPE(VSL_SS_TASK)	Descriptor of the task
sum	REAL(KIND=4) DIMENSION(*) for vslssseditsums REAL(KIND=8) DIMENSION(*) for vsldsseditsums	Pointer to the array of sums
r2s	REAL(KIND=4) DIMENSION(*) for vslssseditsums REAL(KIND=8) DIMENSION(*) for vsldsseditsums	Pointer to the array of raw sums of the second order
r3s	REAL(KIND=4) DIMENSION(*) for vslssseditsums REAL(KIND=8) DIMENSION(*) for vsldsseditsums	Pointer to the array of raw sums of the third order
r4s	REAL(KIND=4) DIMENSION(*) for vslssseditsums REAL(KIND=8) DIMENSION(*) for vsldsseditsums	Pointer to the array of raw sums of the fourth order
c2s	REAL(KIND=4) DIMENSION(*) for vslssseditsums REAL(KIND=8) DIMENSION(*) for vsldsseditsums	Pointer to the array of central sums of the second order
c3s	REAL(KIND=4) DIMENSION(*) for vslssseditsums REAL(KIND=8) DIMENSION(*) for vsldsseditsums	Pointer to the array of central sums of the third order
c4s	REAL(KIND=4) DIMENSION(*) for vslssseditsums REAL(KIND=8) DIMENSION(*) for vsldsseditsums	Pointer to the array of central sums of the fourth order

Output Parameters

Name	Type	Description
status	INTEGER	Current status of the task

Description

The vslSSEditSums routine replaces pointers to the arrays that hold estimates of raw and central sums with values passed as corresponding parameters of the routine. If you pass a value of NULL for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

vslSSEditCovCor

Modifies the pointers to covariance/correlation/cross-product parameters.

Syntax

status = vslssseditcovcor(*task*, *mean*, *cov*, *cov_storage*, *cor*, *cor_storage*)

status = vsldsseditcovcor(*task*, *mean*, *cov*, *cov_storage*, *cor*, *cor_storage*)

Include Files

- mkl_vsl.f90

Input Parameters

Name	Type	Description
task	TYPE(VSL_SS_TASK)	Descriptor of the task
mean	REAL(KIND=4) DIMENSION(*) for vslssseditcovcor REAL(KIND=8) DIMENSION(*) for vsldsseditcovcor	Pointer to the array of means
cov	REAL(KIND=4) DIMENSION(*) for vslssseditcovcor REAL(KIND=8) DIMENSION(*) for vsldsseditcovcor	Pointer to a covariance matrix
cov_storage	INTEGER	Pointer to the storage format of the covariance matrix
cor	REAL(KIND=4) DIMENSION(*) for vslssseditcovcor REAL(KIND=8) DIMENSION(*) for vsldsseditcovcor	Pointer to a correlation matrix
cor_storage	INTEGER	Pointer to the storage format of the correlation matrix

Output Parameters

Name	Type	Description
status	INTEGER	Current status of the task

Description

The `vslSSEditCovCor` routine replaces pointers to the array of means, covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

The storage parameters, *cov_storage* and *cor_storage*, describe the storage format used for the *p*-by-*p* symmetric variance-covariance/correlation/cross-product matrix *C*. The matrix *C* can be described as

$$C = \begin{pmatrix} c_{1,1} & c_{1,2} & \cdots & \cdots & \cdots & c_{1,p} \\ c_{2,1} & c_{2,2} & \cdots & \cdots & \cdots & c_{2,p} \\ \vdots & \vdots & \ddots & & & \vdots \\ \vdots & \vdots & & c_{i,j} & & \vdots \\ \vdots & \vdots & & & \ddots & \vdots \\ c_{p,1} & c_{p,2} & \cdots & \cdots & \cdots & c_{p,p} \end{pmatrix}$$

Table "Storage formats of a variance-covariance/correlation/cross-product matrix" shows how the matrix is stored in a one-dimensional array *cp* for different values of the storage parameters.

Storage formats of variance-covariance/correlation/cross-product matrices

Parameter	Description
`VSL_SS_MATRIX_STORAGE_FULL`	The array *cp* contains all elements of the matrix stored sequentially, column-by-column: *cp*(1) contains $c_{1,1}$ *cp*(2) contains $c_{2,1}$ *cp*(*p*) contains $c_{p,1}$ *cp*(*p* + 1) contains $c_{1,2}$ *cp*(*p***p*) contains $c_{p,p}$ The size of array *cp* is *p***p*.
`VSL_SS_MATRIX_STORAGE_L_PACKED`	The array *cp* contains the lower triangular part of the symmetric matrix stored sequentially, column-by-column: *cp*(1) contains $c_{1,1}$ *cp*(2) contains $c_{2,1}$ *cp*(3) contains $c_{3,1}$ and so on. The size of the array is *p**(*p*+ 1)/2.
`VSL_SS_MATRIX_STORAGE_U_PACKED`	The array *cp* contains the upper triangular part of the symmetric matrix stored sequentially, column-by-column: *cp*(1) contains $c_{1,1}$ *cp*(2) contains $c_{1,2}$

Parameter	Description
	`cp(3)` contains $c_{2,2}$ and so on. The size of the array is $p*(p+1)/2$.

vslSSEditCP

Modifies the pointers to cross-product matrix parameters.

Syntax

```
status = vslssseditcp(task, mean, sum, cp, cp_storage)
status = vsldsseditcp(task, mean, sum, cp, cp_storage)
```

Include Files

- `mkl_vsl.f90`

Input Parameters

Name	Type	Description
task	`TYPE(VSL_SS_TASK)`	Descriptor of the task
mean	`REAL(KIND=4) DIMENSION(*)` for `vslssseditcp` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditcp`	Pointer to array of means
sum	`REAL(KIND=4) DIMENSION(*)` for `vslssseditcp` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditcp`	Pointer to array of sums
cp	`REAL(KIND=4) DIMENSION(*)` for `vslssseditcp` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditcp`	Pointer to a cross-product matrix
cp_storage	`INTEGER`	Pointer to the storage format of the cross-product matrix

Output Parameters

Name	Type	Description
status	`INTEGER`	Current status of the task

Description

The `vslSSEditCP` routine replaces pointers to the array of means, array of sums, cross-product matrix, and its storage format with values passed as corresponding parameters of the routine. See Table: "Storage formats of a variance-covariance/correlation/cross-product matrix" for possible values of the *cp_storage* parameter. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

Storage formats of variance-covariance/correlation/cross-product matrices

Parameter	Description
`VSL_SS_MATRIX_STORAGE_FULL`	The array *cp* contains all elements of the matrix stored sequentially, column-by-column: *cp*(1) contains $c_{1,1}$ *cp*(2) contains $c_{2,1}$ *cp*(*p*) contains $c_{p,1}$ *cp*(*p* + 1) contains $c_{1,2}$ *cp*(*p***p*) contains $c_{p,p}$ The size of array *cp* is *p***p*.
`VSL_SS_MATRIX_STORAGE_L_PACKED`	The array *cp* contains the lower triangular part of the symmetric matrix stored sequentially, column-by-column: *cp*(1) contains $c_{1,1}$ *cp*(2) contains $c_{2,1}$ *cp*(3) contains $c_{3,1}$ and so on. The size of the array is *p**(*p*+ 1)/2.
`VSL_SS_MATRIX_STORAGE_U_PACKED`	The array *cp* contains the upper triangular part of the symmetric matrix stored sequentially, column-by-column: *cp*(1) contains $c_{1,1}$ *cp*(2) contains $c_{1,2}$ *cp*(3) contains $c_{2,2}$ and so on. The size of the array is *p**(*p*+ 1)/2.

vslSSEditPartialCovCor

Modifies the pointers to partial covariance/correlation parameters.

Syntax

status = vslsssedit partialcovcor(*task*, *p_idx_array*, *cov*, *cov_storage*, *cor*, *cor_storage*, *p_cov*, *p_cov_storage*, *p_cor*, *p_cor_storage*)

status = vsldsseditpartialcovcor(*task*, *p_idx_array*, *cov*, *cov_storage*, *cor*, *cor_storage*, *p_cov*, *p_cov_storage*, *p_cor*, *p_cor_storage*)

Include Files

- mkl_vsl.f90

Input Parameters

Name	Type	Description
task	TYPE(VSL_SS_TASK)	Descriptor of the task
p_idx_array	INTEGER	Pointer to the array that encodes indices of subcomponents *Z* and *Y* of the random vector as described in section Mathematical Notation and Definitions. *p_idx_array[i]* equals to -1 if the *i*-th component of the random vector belongs to *Z* 1, if the *i*-th component of the random vector belongs to *Y*.
cov	REAL(KIND=4) DIMENSION(*) for vslsssseditpartialcovcor REAL(KIND=8) DIMENSION(*) for vsldsseditpartialcovcor	Pointer to a covariance matrix
cov_storage	INTEGER	Pointer to the storage format of the covariance matrix
cor	REAL(KIND=4) DIMENSION(*) for vslsssseditpartialcovcor REAL(KIND=8) DIMENSION(*) for vsldsseditpartialcovcor	Pointer to a correlation matrix
cor_storage	INTEGER	Pointer to the storage format of the correlation matrix
p_cov	REAL(KIND=4) DIMENSION(*) for vslsssseditpartialcovcor REAL(KIND=8) DIMENSION(*) for vsldsseditpartialcovcor	Pointer to a partial covariance matrix
p_cov_storage	INTEGER	Pointer to the storage format of the partial covariance matrix
p_cor	REAL(KIND=4) DIMENSION(*) for vslsssseditpartialcovcor REAL(KIND=8) DIMENSION(*) for vsldsseditpartialcovcor	Pointer to a partial correlation matrix
p_cor_storage	INTEGER	Pointer to the storage format of the partial correlation matrix

Output Parameters

Name	Type	Description
status	INTEGER	Current status of the task

Description

The vslSSEditPartialCovCor routine replaces pointers to covariance/correlation arrays, partial covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. See Table "Storage formats of a variance-covariance/correlation matrix" for possible values of the *cov_storage*, *cor_storage*, *p_cov_storage*, and *p_cor_storage* parameters. If you pass a value of NULL for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

vslSSEditQuantiles

Modifies the pointers to parameters related to quantile computations.

Syntax

status = vslssseditquantiles(*task*, *quant_order_n*, *quant_order*, *quants*, *order_stats*, *order_stats_storage*)

status = vsldsseditquantiles(*task*, *quant_order_n*, *quant_order*, *quants*, *order_stats*, *order_stats_storage*)

Include Files

- mkl_vsl.f90

Input Parameters

Name	Type	Description
task	TYPE(VSL_SS_TASK)	Descriptor of the task
quant_order_n	INTEGER	Pointer to the number of quantile orders
quant_order	REAL(KIND=4) DIMENSION(*) for vslssseditquantiles REAL(KIND=8) DIMENSION(*) for vsldsseditquantiles	Pointer to the array of quantile orders
quants	REAL(KIND=4) DIMENSION(*) for vslssseditquantiles REAL(KIND=8) DIMENSION(*) for vsldsseditquantiles	Pointer to the array of quantiles
order_stats	REAL(KIND=4) DIMENSION(*) for vslssseditquantiles REAL(KIND=8) DIMENSION(*) for vsldsseditquantiles	Pointer to the array of order statistics
order_stats_storage	INTEGER	Pointer to the storage format of the order statistics array

Output Parameters

Name	Type	Description
status	INTEGER	Current status of the task

Description

The vslSSEditQuantiles routine replaces pointers to the number of quantile orders, the array of quantile orders, the array of quantiles, the array that holds order statistics, and the storage format for the order statistics with values passed into the routine. See Table "Storage format of matrix of observations and order statistics" for possible values of the *order_statistics_storage* parameter. If you pass a value of NULL for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

vslSSEditStreamQuantiles

Modifies the pointers to parameters related to quantile computations for streaming data.

Syntax

status = vslsssseditstreamquantiles(*task*, *quant_order_n*, *quant_order*, *quants*, *nparams*, *params*)

status = vsldsseditstreamquantiles(*task*, *quant_order_n*, *quant_order*, *quants*, *nparams*, *params*)

Include Files

- mkl_vsl.f90

Input Parameters

Name	Type	Description
task	TYPE(VSL_SS_TASK)	Descriptor of the task
quant_order_n	INTEGER	Pointer to the number of quantile orders
quant_order	REAL(KIND=4) DIMENSION(*) for vslsssseditstreamquantiles REAL(KIND=8) DIMENSION(*) for vsldsseditstreamquantiles	Pointer to the array of quantile orders
quants	REAL(KIND=4) DIMENSION(*) for vslsssseditstreamquantiles REAL(KIND=8) DIMENSION(*) for vsldsseditstreamquantiles	Pointer to the array of quantiles
nparams	INTEGER	Pointer to the number of the algorithm parameters
params	REAL(KIND=4) DIMENSION(*) for vslsssseditstreamquantiles REAL(KIND=8) DIMENSION(*)	Pointer to the array of the algorithm parameters

Name	Type	Description
	for `vsldsseditstreamquantiles`	

Output Parameters

Name	Type	Description
status	`INTEGER`	Current status of the task

Description

The `vslSSEditStreamQuantiles` routine replaces pointers to the number of quantile orders, the array of quantile orders, the array of quantiles, the number of the algorithm parameters, and the array of the algorithm parameters with values passed into the routine. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

vslSSEditPooledCovariance

Modifies pooled/group covariance matrix array pointers.

Syntax

status = vslssseditpooledcovariance(*task*, *grp_indices*, *pld_mean*, *pld_cov*, *req_grp_indices*, *grp_means*, *grp_cov*)

status = vsldsseditpooledcovariance(*task*, *grp_indices*, *pld_mean*, *pld_cov*, *req_grp_indices*, *grp_means*, *grp_cov*)

Include Files

- `mkl_vsl.f90`

Input Parameters

Name	Type	Description
task	`TYPE(VSL_SS_TASK)`	Descriptor of the task
grp_indices	`INTEGER DIMENSION(*)`	Pointer to an array of size *n*. The *i*-th element of the array contains the number of the group the observation belongs to.
pld_mean	`REAL(KIND=4) DIMENSION(*)` for `vslssseditpooledcovariance` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditpooledcovariance`	Pointer to the array of pooled means
pld_cov	`REAL(KIND=4) DIMENSION(*)` for `vslssseditpooledcovariance` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditpooledcovariance`	Pointer to the array that holds a pooled covariance matrix
req_grp_indices	`INTEGER DIMENSION(*)`	Pointer to the array that contains indices of groups for which estimates to return (such as covariance and mean)

Name	Type	Description
grp_means	REAL(KIND=4) DIMENSION(*) for product=Fortran vslssseditpooledcovariance REAL(KIND=8) DIMENSION(*) for vsldsseditpooledcovariance	Pointer to the array of group means
grp_cov	REAL(KIND=4) DIMENSION(*) for vslssseditpooledcovariance REAL(KIND=8) DIMENSION(*) for vsldsseditpooledcovariance	Pointer to the array that holds group covariance matrices

Output Parameters

Name	Type	Description
status	INTEGER	Current status of the task

Description

The vslSSEditPooledCovariance routine replaces pointers to the array of group indices, the array of pooled means, the array for a pooled covariance matrix, and pointers to the array of indices of group matrices, the array of group means, and the array for group covariance matrices with values passed in the editors. If you pass a value of NULL for a specific input parameter, the value of that parameter in the task descriptor is unchanged.. Use the vslSSEditTask routine to replace the storage format for pooled and group covariance matrices.

vslSSEditRobustCovariance

Modifies pointers to arrays related to a robust covariance matrix.

Syntax

```
status = vslssseditrobustcovariance(task, rcov_storage, nparams, params, rmean, rcov)
status = vsldsseditrobustcovariance(task, rcov_storage, nparams, params, rmean, rcov)
```

Include Files

- mkl_vsl.f90

Input Parameters

Name	Type	Description
task	TYPE(VSL_SS_TASK)	Descriptor of the task
rcov_storage	INTEGER	Pointer to the storage format of a robust covariance matrix
nparams	INTEGER	Pointer to the number of method parameters
params	REAL(KIND=4) DIMENSION(*) for vslssseditrobustcovariance	Pointer to the array of method parameters

Name	Type	Description
	`REAL(KIND=8) DIMENSION(*)` for `vsldsseditrobustcovariance`	
rmean	`REAL(KIND=4) DIMENSION(*)` for `vslsssseditrobustcovariance` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditrobustcovariance`	Pointer to the array of robust means
rcov	`REAL(KIND=4) DIMENSION(*)` for `vslsssseditrobustcovariance` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditrobustcovariance`	Pointer to a robust covariance matrix

Output Parameters

Name	Type	Description
status	`INTEGER`	Current status of the task

Description

The `vslSSEditRobustCovariance` routine uses values passed as parameters of the routine to replace:

- pointers to covariance matrix storage
- pointers to the number of method parameters and to the array of the method parameters of size *nparams*
- pointers to the arrays that hold robust means and covariance

See Table "Storage formats of a variance-covariance/correlation matrix" for possible values of the *rcov_storage* parameter. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

Intel® oneAPI Math Kernel Library (oneMKL) provides a Translated Biweight S-estimator (TBS) for robust estimation of a variance-covariance matrix and mean [Rocke96]. Use one iteration of the Maronna algorithm with the reweighting step [Maronna02] to compute the initial point of the algorithm. Pack the parameters of the TBS algorithm into the *params* array and pass them into the editor. Table "Structure of the Array of TBS Parameters" describes the *params* structure.

Structure of the Array of TBS Parameters

Array Position	Algorithm Parameter	Description
0	ε	Breakdown point, the number of outliers the algorithm can hold. By default, the value is $(n-p)/(2n)$.
1	α	Asymptotic rejection probability, see details in [Rocke96]. By default, the value is 0.001.
2	δ	Stopping criterion: the algorithm is terminated if weights are changed less than δ. By default, the value is 0.001.

Array Position	Algorithm Parameter	Description
3	max_iter	Maximum number of iterations. The algorithm terminates after max_iter iterations. By default, the value is 10. If you set this parameter to zero, the function returns a robust estimate of the variance-covariance matrix computed using the Maronna method [Maronna02] only.

The robust estimator of variance-covariance implementation in Intel® oneAPI Math Kernel Library (oneMKL) requires that the number of observations*n* be greater than twice the number of variables: $n > 2p$.

See additional details of the algorithm usage model in the *Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes* document [SS Notes].

vslSSEditOutliersDetection

Modifies array pointers related to multivariate outliers detection.

Syntax

```
status = vslssseditoutliersdetection(task, nparams, params, w)
status = vsldsseditoutliersdetection(task, nparams, params, w)
```

Include Files

- mkl_vsl.f90

Input Parameters

Name	Type	Description
task	TYPE(VSL_SS_TASK)	Descriptor of the task
nparams	INTEGER	Pointer to the number of method parameters
params	REAL(KIND=4) DIMENSION(*) for vslssseditoutliersdetection REAL(KIND=8) DIMENSION(*) for vsldsseditoutliersdetection	Pointer to the array of method parameters
w	REAL(KIND=4) DIMENSION(*) for vslssseditoutliersdetection REAL(KIND=8) DIMENSION(*) for vsldsseditoutliersdetection	Pointer to an array of size *n*. The array holds the weights of observations to be marked as outliers.

Output Parameters

Name	Type	Description
status	INTEGER	Current status of the task

Description

The `vslSSEditOutliersDetection` routine uses the parameters passed to replace

- the pointers to the number of method parameters and to the array of the method parameters of size *nparams*
- the pointer to the array that holds the calculated weights of the observations

If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

Intel® oneAPI Math Kernel Library (oneMKL) provides the BACON algorithm ([Billor00]) for the detection of multivariate outliers. Pack the parameters of the BACON algorithm into the *params* array and pass them into the editor. Table "Structure of the Array of BACON Parameters" describes the *params* structure.

Structure of the Array of BACON Parameters

Array Position	Algorithm Parameter	Description
0	Method to start the algorithm	The parameter takes one of the following possible values: `VSL_SS_METHOD_BACON_MEDIAN_INIT`, if the algorithm is started using the median estimate. This is the default value of the parameter. `VSL_SS_METHOD_BACON_MAHALANOBIS_INIT`, if the algorithm is started using the Mahalanobis distances.
1	α	One-tailed probability that defines the `(1 – α)` quantile of χ^2 distribution with `p` degrees of freedom. The recommended value is `α/ n`, where `n` is the number of observations. By default, the value is 0.05.
2	δ	Stopping criterion; the algorithm is terminated if the size of the basic subset is changed less than δ. By default, the value is 0.005.

Output of the algorithm is the vector of weights, `BaconWeights`, such that `BaconWeights`(*i*) = 0 if *i*-th observation is detected as an outlier. Otherwise `BaconWeights`(*i*) = *w*(*i*), where *w* is the vector of input weights. If you do not provide the vector of input weights, `BaconWeights`(*i*) is set to 1 if the *i*-th observation is not detected as an outlier.

See additional details about usage model of the algorithm in the *Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes* document [SS Notes].

vslSSEditMissingValues

Modifies pointers to arrays associated with the method of supporting missing values in a dataset.

Syntax

status = vslssseditmissingvalues(*task*, *nparams*, *params*, *init_estimates_n*, *init_estimates*, *prior_n*, *prior*, *simul_missing_vals_n*, *simul_missing_vals*, *estimates_n*, *estimates*)

status = vsldsseditmissingvalues(*task*, *nparams*, *params*, *init_estimates_n*, *init_estimates*, *prior_n*, *prior*, *simul_missing_vals_n*, *simul_missing_vals*, *estimates_n*, *estimates*)

Include Files

- mkl_vsl.f90

Input Parameters

Name	Type	Description
task	TYPE(VSL_SS_TASK)	Descriptor of the task
nparams	INTEGER	Pointer to the number of method parameters
params	REAL(KIND=4) DIMENSION(*) for vslsssseditmissingvalues REAL(KIND=8) DIMENSION(*) for vsldsseditmissingvalues	Pointer to the array of method parameters
init_estimates_n	INTEGER	Pointer to the number of initial estimates for mean and a variance-covariance matrix
init_estimates	REAL(KIND=4) DIMENSION(*) for vslsssseditmissingvalues REAL(KIND=8) DIMENSION(*) for vsldsseditmissingvalues	Pointer to the array that holds initial estimates for mean and a variance-covariance matrix
prior_n	INTEGER	Pointer to the number of prior parameters
prior	REAL(KIND=4) DIMENSION(*) for vslsssseditmissingvalues REAL(KIND=8) DIMENSION(*) for vsldsseditmissingvalues	Pointer to the array of prior parameters
simul_missing_vals_n	INTEGER	Pointer to the size of the array that holds output of the Multiple Imputation method
simul_missing_vals	REAL(KIND=4) DIMENSION(*) for vslsssseditmissingvalues REAL(KIND=8) DIMENSION(*) for vsldsseditmissingvalues	Pointer to the array of size *k*m*, where *k* is the total number of missing values, and *m* is number of copies of missing values. The array holds *m* sets of simulated missing values for the matrix of observations.
estimates_n	INTEGER	Pointer to the number of estimates to be returned by the routine
estimates	REAL(KIND=4) DIMENSION(*) for vslsssseditmissingvalues REAL(KIND=8) DIMENSION(*) for vsldsseditmissingvalues	Pointer to the array that holds estimates of the mean and a variance-covariance matrix.

Output Parameters

Name	Type	Description
status	INTEGER	Current status of the task

Description

The vslSSEditMissingValues routine uses values passed as parameters of the routine to replace pointers to the number and the array of the method parameters, pointers to the number and the array of initial mean/variance-covariance estimates, the pointer to the number and the array of prior parameters, pointers to the number and the array of simulated missing values, and pointers to the number and the array of the intermediate mean/covariance estimates. If you pass a value of NULL for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

Before you call the Summary Statistics routines to process missing values, preprocess the dataset and denote missing observations with one of the following predefined constants:

- VSL_SS_SNAN, if the dataset is stored in single precision floating-point arithmetic
- VSL_SS_DNAN, if the dataset is stored in double precision floating-point arithmetic

Intel® oneAPI Math Kernel Library (oneMKL) provides theVSL_SS_METHOD_MI method to support missing values in the dataset based on the Multiple Imputation (MI) approach described in [Schafer97]. The following components support Multiple Imputation:

- Expectation Maximization (EM) algorithm to compute the start point for the Data Augmentation (DA) procedure
- DA function

> **NOTE**
> The DA component of the MI procedure is simulation-based and uses the VSL_BRNG_MCG59 basic random number generator with predefined *seed* = 2^{50} and the Gaussian distribution generator (ICDFmethod) available in Intel® oneAPI Math Kernel Library (oneMKL) [Gaussian].

Pack the parameters of the MI algorithm into the *params* array. Table "Structure of the Array of MI Parameters" describes the *params* structure.

Structure of the Array of MI Parameters

Array Position	Algorithm Parameter	Description
0	em_iter_num	Maximal number of iterations for the EM algorithm. By default, this value is 50.
1	da_iter_num	Maximal number of iterations for the DA algorithm. By default, this value is 30.
2	ε	Stopping criterion for the EM algorithm. The algorithm terminates if the maximal module of the element-wise difference between the previous and current parameter values is less than ε. By default, this value is 0.001.
3	m	Number of sets to impute
4	missing_vals_num	Total number of missing values in the datasets

You can also pass initial estimates into the EM algorithm by packing both the vector of means and the variance-covariance matrix as a one-dimensional array *init_estimates*. The size of the array should be at least $p + p(p + 1)/2$. For $i=0, .., p-1$, the *init_estimates*[*i*] array contains the initial estimate of means. The remaining positions of the array are occupied by the upper triangular part of the variance-covariance matrix.

If you provide no initial estimates for the EM algorithm, the editor uses the default values, that is, the vector of zero means and the unitary matrix as a variance-covariance matrix. You can also pass *prior* parameters for μ and Σ into the library: μ_0, τ, *m*, and Λ^{-1}. Pack these parameters as a one-dimensional array *prior* with a size of at least

$(p^2 + 3p + 4)/2$.

The storage format is as follows:

- *prior*[0], ..., *prior*[*p*–1] contain the elements of the vector μ_0.
- *prior*[*p*] contains the parameter τ.
- *prior*[*p*+1] contains the parameter *m*.
- The remaining positions are occupied by the upper-triangular part of the inverted matrix Λ^{-1}.

If you provide no *prior* parameters, the editor uses their default values:

- The array of *p* zeros is used as μ_0.
- τ is set to 0.
- *m* is set to *p*.
- The zero matrix is used as an initial approximate of Λ^{-1}.

The `EditMissingValues` editor returns *m* sets of imputed values and/or a sequence of parameter estimates drawn during the DA procedure.

The editor returns the imputed values as the *simul_missing_vals* array. The size of the array should be sufficient to hold *m* sets each of the `missing_vals_num` size, that is, at least *m**`missing_vals_num` in total. The editor packs the imputed values one by one in the order of their appearance in the matrix of observations.

For example, consider a task of dimension 4. The total number of observations *n* is 10. The second observation vector misses variables 1 and 2, and the seventh observation vector lacks variable 1. The number of sets to impute is *m*=2. Then, *simul_missing_vals*[0] and *simul_missing_vals*[1] contains the first and the second points for the second observation vector, and *simul_missing_vals*[2] holds the first point for the seventh observation. Positions 3, 4, and 5 are formed similarly.

To estimate convergence of the DA algorithm and choose a proper value of the number of DA iterations, request the sequence of parameter estimates that are produced during the DA procedure. The editor returns the sequence of parameters as a single array. The size of the array is

*m**da_iter_num*(*p*+(*p*^{2}+*p*)/2)

where

- *m* is the number of sets of values to impute.
- `da_iter_num` is the number of DA iterations.
- The value *p*+(*p*^{2}+*p*)/2 determines the size of the memory to hold one set of the parameter estimates.

In each set of the parameters, the vector of means occupies the first *p* positions and the remaining (*p*^{2}+*p*)/2 positions are intended for the upper triangular part of the variance-covariance matrix.

Upon successful generation of *m* sets of imputed values, you can place them in cells of the data matrix with missing values and use the Summary Statistics routines to analyze and get estimates for each of the *m* complete datasets.

NOTE
Intel® oneAPI Math Kernel Library (oneMKL) implementation of the MI algorithm rewrites cells of the dataset that contain the`VSL_SS_SNAN/VSL_SS_DNAN` values. If you want to use the Summary Statistics routines to process the data with missing values again, mask the positions of the empty cells.

See additional details of the algorithm usage model in the *Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes* document [SS Notes].

vslSSEditCorParameterization

Modifies pointers to arrays related to the algorithm of correlation matrix parameterization.

Syntax

```
status = vslsssseditcorparameterization(task, cor, cor_storage, pcor, pcor_storage)
status = vsldsseditcorparameterization(task, cor, cor_storage, pcor, pcor_storage)
```

Include Files

- `mkl_vsl.f90`

Input Parameters

Name	Type	Description
task	`TYPE(VSL_SS_TASK)`	Descriptor of the task
cor	`REAL(KIND=4) DIMENSION(*)` for `vslsssseditcorparameterization` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditcorparameterization`	Pointer to the correlation matrix
cor_storage	`INTEGER`	Pointer to the storage format of the correlation matrix
pcor	`REAL(KIND=4) DIMENSION(*)` for `vslsssseditcorparameterization` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditcorparameterization`	Pointer to the parameterized correlation matrix
por_storage	`INTEGER`	Pointer to the storage format of the parameterized correlation matrix

Output Parameters

Name	Type	Description
status	`INTEGER`	Current status of the task

Description

The `vslSSEditCorParameterization` routine uses values passed as parameters of the routine to replace pointers to the correlation matrix, pointers to the correlation matrix storage format, a pointer to the parameterized correlation matrix, and a pointer to the parameterized correlation matrix storage format. See

Table "Storage formats of a variance-covariance/correlation matrix" for possible values of the *cor_storage* and *pcor_storage* parameters. If you pass a value of NULL for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

Summary Statistics Task Computation Routines

Task computation routines calculate statistical estimates on the data provided and parameters held in the task descriptor. After you create the task and initialize its parameters, you can call the computation routines as many times as necessary. Table "Summary Statistics Estimates Obtained with vslSSCompute Routine" lists the respective statistical estimates.

NOTE
The Summary Statistics computation routines do not signal floating-point errors, such as overflow or gradual underflow, or operations with NaNs (except for the missing values in the observations).

Summary Statistics Estimates Obtained with vslSSCompute Routine

Estimate	Support of Observations Available in Blocks	Description
VSL_SS_MEAN	Yes	Computes the array of means.
VSL_SS_SUM	Yes	Computes the array of sums.
VSL_SS_2R_MOM	Yes	Computes the array of the 2nd order raw moments.
VSL_SS_2R_SUM	Yes	Computes the array of raw sums of the 2nd order.
VSL_SS_3R_MOM	Yes	Computes the array of the 3rd order raw moments.
VSL_SS_3R_SUM	Yes	Computes the array of raw sums of the 3rd order.
VSL_SS_4R_MOM	Yes	Computes the array of the 4th order raw moments.
VSL_SS_4R_SUM	Yes	Computes the array of raw sums of the 4th order.
VSL_SS_2C_MOM	Yes	Computes the array of the 2nd order central moments.
VSL_SS_2C_SUM	Yes	Computes the array of central sums of the 2nd order.
VSL_SS_3C_MOM	Yes	Computes the array of the 3rd order central moments.
VSL_SS_3C_SUM	Yes	Computes the array of central sums of the 3rd order.
VSL_SS_4C_MOM	Yes	Computes the array of the 4th order central moments.
VSL_SS_4C_SUM	Yes	Computes the array of central sums of the 4th order.

Estimate	Support of Observations Available in Blocks	Description
VSL_SS_KURTOSIS	Yes	Computes the array of kurtosis values.
VSL_SS_SKEWNESS	Yes	Computes the array of skewness values.
VSL_SS_MIN	Yes	Computes the array of minimum values.
VSL_SS_MAX	Yes	Computes the array of maximum values.
VSL_SS_VARIATION	Yes	Computes the array of variation coefficients.
VSL_SS_COV	Yes	Computes a covariance matrix.
VSL_SS_COR	Yes	Computes a correlation matrix. The main diagonal of the correlation matrix holds variances of the random vector components.
VSL_SS_CP	Yes	Computes a cross-product matrix.
VSL_SS_POOLED_COV	No	Computes a pooled covariance matrix.
VSL_SS_POOLED_MEAN	No	Computes an array of pooled means.
VSL_SS_GROUP_COV	No	Computes group covariance matrices.
VSL_SS_GROUP_MEAN	No	Computes group means.
VSL_SS_QUANTS	No	Computes quantiles.
VSL_SS_ORDER_STATS	No	Computes order statistics.
VSL_SS_ROBUST_COV	No	Computes a robust covariance matrix.
VSL_SS_OUTLIERS	No	Detects outliers in the dataset.
VSL_SS_PARTIAL_COV	No	Computes a partial covariance matrix.
VSL_SS_PARTIAL_COR	No	Computes a partial correlation matrix.
VSL_SS_MISSING_VALS	No	Supports missing values in datasets.
VSL_SS_PARAMTR_COR	No	Computes a parameterized correlation matrix.
VSL_SS_STREAM_QUANTS	Yes	Computes quantiles for streaming data.
VSL_SS_MDAD	No	Computes median absolute deviation.
VSL_SS_MNAD	No	Computes mean absolute deviation.
VSL_SS_SORTED_OBSERV	No	Sorts the dataset by the components of the random vector ξ.

Table "Summary Statistics Computation Method"lists estimate calculation methods supported by Intel® oneAPI Math Kernel Library (oneMKL). See the*Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes* document [SS Notes] for a detailed description of the methods.

Summary Statistics Computation Method

Method	Description
VSL_SS_METHOD_FAST	Fast method for calculation of the estimates:

Method	Description
	• raw/central moments/sums, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix • min/max/quantile/order statistics • partial variance-covariance • median/mean absolute deviation
VSL_SS_METHOD_FAST_USER_MEAN	Fast method for calculation of the estimates given user-defined mean: • central moments/sums of 2-4 order, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix, mean absolute deviation
VSL_SS_METHOD_1PASS	One-pass method for calculation of estimates: • raw/central moments/sums, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix • pooled/group covariance matrix
VSL_SS_METHOD_TBS	TBS method for robust estimation of covariance and mean
VSL_SS_METHOD_BACON	BACON method for detection of multivariate outliers
VSL_SS_METHOD_MI	Multiple imputation method for support of missing values
VSL_SS_METHOD_SD	Spectral decomposition method for parameterization of a correlation matrix
VSL_SS_METHOD_SQUANTS_ZW	Zhang-Wang (ZW) method for quantile estimation for streaming data
VSL_SS_METHOD_SQUANTS_ZW_FAST	Fast ZW method for quantile estimation for streaming data
VSL_SS_METHOD_RADIX	Radix method for dataset sorting

You can calculate all requested estimates in one call of the routine. For example, to compute a kurtosis and covariance matrix using a fast method, pass a combination of the pre-defined parameters into the `Compute` routine as shown in the example below:

```
...
method = VSL_SS_METHOD_FAST;
task_params = VSL_SS_KURTOSIS|VSL_SS_COV;
…
status = vsldSSCompute( task, task_params, method );
```

To compute statistical estimates for the next block of observations, you can do one of the following:

- copy the observations to memory, starting with the address available to the task
- use one of the appropriate Editors to modify the pointer to the new dataset in the task.

The library does not detect your changes of the dataset and computed statistical estimates. To obtain statistical estimates for a new matrix, change the observations and initialize relevant arrays. You can follow this procedure to compute statistical estimates for observations that come in portions. See Table "Summary Statistics Estimates Obtained with `vslSSCompute` Routine"for information on such observations supported by the Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics estimators.

To modify parameters of the task using the Task Editors, set the address of the targeted matrix of the observations or change the respective vector component indices. After you complete editing the task parameters, you can compute statistical estimates in the modified environment.

If the task completes successfully, the computation routine returns the zero status code. If an error is detected, the computation routine returns an error code. In particular, an error status code is returned in the following cases:

- the task pointer is `NULL`
- memory allocation has failed
- the calculation has failed for some other reason

> **NOTE**
> You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

vslSSCompute

Computes Summary Statistics estimates.

Syntax

```
status = vslssscompute(task, estimates, method)
status = vsldsscompute(task, estimates, method)
```

Include Files

- `mkl_vsl.f90`

Input Parameters

Name	Type	Description
task	`TYPE(VSL_SS_TASK)`	Descriptor of the task
estimates	`INTEGER (KIND=8)`	List of statistical estimates to compute
method	`INTEGER`	Method to be used in calculations

Output Parameters

Name	Type	Description
status	`INTEGER`	Current status of the task

Description

The `vslSSCompute` routine calculates statistical estimates passed as the *estimates* parameter using the algorithms passed as the *method* parameter of the routine. The computations are done in the context of the task descriptor that contains pointers to all required and optional, if necessary, properly initialized arrays. In one call of the function, you can compute several estimates using proper methods for their calculation. See Table "Summary Statistics Estimates Obtained with `Compute` Routine" for the list of the estimates that you can calculate with the `vslSSCompute` routine. See Table "Summary Statistics Computation Methods" for the list of possible values of the *method* parameter.

To initialize single or double precision version task parameters, use the single (`vslssscompute`) or double (`vsldsscompute`) version of the editor, respectively. To initialize parameters of the integer type, use an integer version of the editor (`vslisscompute`).

NOTE
Requesting a combination of the VSL_SS_MISSING_VALS value and any other estimate parameter in the Compute function results in processing only the missing values.

Application Notes

Be aware that when computing a correlation matrix, the vslSSCompute routine allocates an additional array for each thread which is running the task. If you are running on a large number of threads vslSSCompute might consume large amounts of memory.

When calculating covariance, correlation, or cross product, the number of bytes of memory required is at least (*P***P***T* + *P***T*)**b*, where *P* is the dimension of the task or number of variables, *T* is the number of threads, and *b* is the number of bytes required for each unit of data. If observation is weighted and the method is VSL_SS_METHOD_FAST, then the memory required is at least (*P***P***T* + *P***T* + *N***P*)**b*, where *N* is the number of observations.

Summary Statistics Task Destructor

Task destructor is the vslSSDeleteTask routine intended to delete task objects and release memory.

vslSSDeleteTask

Destroys the task object and releases the memory.

Syntax

status = vslssdeletetask(*task*)

Include Files

- mkl_vsl.f90

Input Parameters

Name	Type	Description
task	TYPE(VSL_SS_TASK)	Descriptor of the task to destroy

Output Parameters

Name	Type	Description
status	INTEGER	Sets to VSL_STATUS_OK if the task is deleted; otherwise a non-zero code is returned.

Description

The vslSSDeleteTask routine deletes the task descriptor object, releases the memory allocated for the structure, and sets the task pointer to NULL. If vslSSDeleteTask fails to delete the task successfully, it returns an error code.

NOTE
Call of the destructor with the NULL pointer as the parameter results in termination of the function with no system crash.

Summary Statistics Usage Examples

The following examples show various standard operations with Summary Statistics routines.

Calculating Fixed Estimates for Fixed Data

The example shows recurrent calculation of the same estimates with a given set of variables for the complete life cycle of the task in the case of a variance-covariance matrix. The set of vector components to process remains unchanged, and the data comes in blocks. Before you call the `vslSSCompute` routine, initialize pointers to arrays for mean and covariance and set buffers.

```
….
double w[2];
double indices[DIM] = {1, 0, 1};

/* calculating mean for 1st and 3d random vector components */

/* Initialize parameters of the task */
p = DIM;
n = N;

xstorage   = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;

w[0] = 0.0; w[1] = 0.0;

for ( i = 0; i < p; i++ ) mean[i] = 0.0;
for ( i = 0; i < p*p; i++ ) cov[i] = 0.0;

status = vsldSSNewTask( &task, &p, &n, &xstorage, x, 0, indices );

status = vsldSSEditTask  ( task, VSL_SS_ED_ACCUM_WEIGHT, w    );
status = vsldSSEditCovCor( task, mean, cov, &covstorage, 0, 0 );
```

You can process data arrays that come in blocks as follows:

```
for ( i = 0; i < num_of_blocks; i++ )
{
    status = vsldSSCompute( task, VSL_SS_COV, VSL_SS_METHOD_FAST );
    /* Read new data block into array x */
}
…
```

Calculating Different Estimates for Variable Data

The context of your calculation may change in the process of data analysis. The example below shows the data that comes in two blocks. You need to estimate a covariance matrix for the complete data, and the third central moment for the second block of the data using the weights that were accumulated for the previous datasets. The second block of the data is stored in another array. You can proceed as follows:

```
/* Set parameters for the task */
p = DIM;
n = N;
xstorage   = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;

w[0] = 0.0; w[1] = 0.0;
```

```
for ( i = 0; i < p; i++ ) mean[i] = 0.0;
for ( i = 0; i < p*p; i++ ) cov[i] = 0.0;

/* Create task */
status = vsldSSNewTask( &task, &p, &n, &xstorage, x1, 0, indices );

/* Initialize the task parameters */
status = vsldSSEditTask( task, VSL_SS_ED_ACCUM_WEIGHT, w );
status = vsldSSEditCovCor( task, mean, cov, &covstorage, 0, 0 );

/* Calculate covariance for the x1 data */
status = vsldSSCompute( task, VSL_SS_COV, VSL_SS_METHOD_FAST );

/* Initialize array of the 3d central moments and pass the pointer to the task */
for ( i = 0; i < p; i++ ) c3_m[i] = 0.0;

/* Modify task context */
status = vsldSSEditTask( task, VSL_SS_ED_3C_MOM, c3_m );
status = vsldSSEditTask( task, VSL_SS_ED_OBSERV, x2 );

/* Calculate covariance for the x1 & x2 data block */
/* Calculate the 3d central moment for the 2nd data block using earlier accumulated weight */
status = vsldSSCompute(task, VSL_SS_COV|VSL_SS_3C_MOM, VSL_SS_METHOD_FAST );
…
status = vslSSDeleteTask( &task );
```

Similarly, you can modify indices of the variables to be processed for the next data block.

Summary Statistics Mathematical Notation and Definitions

The following notations are used in the mathematical definitions and the description of the Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics functions.

Matrix and Weights of Observations

For a random *p*-dimensional vector $\xi = (\xi_1,..., \xi_i,..., \xi_p)$, this manual denotes the following:

- $(X)_i = (x_{ij})_{j=1..n}$ is the result of *n* independent observations for the *i*-th component ξ_i of the vector ξ.
- The two-dimensional array $X = (x_{ij})_{n \times p}$ is the matrix of observations.
- The column $[X]_j = (x_{ij})_{i=1..p}$ of the matrix *X* is the *j*-th observation of the random vector ξ.

Each observation $[X]_j$ is assigned a non-negative weight w_j, where

- The vector $(w_j)_{j=1..n}$ is a vector of weights corresponding to *n* observations of the random vector ξ.
- $W = \sum_{i=1}^{n} w_i$

  is the accumulated weight corresponding to observations *X*.

Vector of sample means

$$M(X) = (M_1(X), ..., M_p(X)) \text{ with } M_i(X) = \frac{1}{w} \sum_{j=1}^{n} w_j x_{ij}$$

for all $i = 1, ..., p$.

Vector of sample partial sums

$S(X) = \left(S_1(X), ..., S_p(X)\right)$ with $S_i(X) = \sum_{j=1}^{n} w_j x_{ij}$

for all *i* = 1, ..., *p*.

Vector of sample variances

$V(X) = \left(V_1(X), ..., V_p(X)\right)$ with $V_i(X) = \frac{1}{B}\sum_{j=1}^{n} w_j\left(x_{ij} - M_i(X)\right)^2$, $B = W - \sum_{j=1}^{n} w_j^2 / W$

for all *i* = 1, ..., *p*.

Vector of sample raw/algebraic moments of *k*-th order, *k*≥ 1

$R^{(k)}(X) = \left(R_1^{(k)}(X), ..., R_p^{(k)}(X)\right)$ with $R_i^{(k)}(X) = \frac{1}{W}\sum_{j=1}^{n} w_j x_{ij}^k$

for all *i* = 1, ..., *p*.

Vector of sample raw/algebraic partial sums of *k*-th order, *k*= 2, 3, 4 (raw/algebraic partial sums of squares/cubes/fourth powers)

$S^k(X) = \left(S_1^k(X), ..., S_p^k(X)\right)$ with $S_i^k(X) = \sum_{j=1}^{n} w_j x_{ij}^k$

for all *i* = 1, ..., *p*.

Vector of sample central moments of the third and the fourth order

$C^{(k)}(X) = \left(C_1^{(k)}(X), ..., C_p^{(k)}(X)\right)$ with $C_i^{(k)}(X) = \frac{1}{B}\sum_{j=1}^{n} w_j\left(x_{ij} - M_i(X)\right)^k$, $B = \sum_{j=1}^{n} w_j$

for all *i* = 1, ..., *p* and *k* = 3, 4.

Vector of sample central partial sums of *k*-th order, *k*= 2, 3, 4 (central partial sums of squares/cubes/fourth powers)

$S^k(X) = \left(S_1^k(X), ..., S_p^k(X)\right)$ with $S_i^k(X) = \sum_{j=1}^{n} w_j\left(x_{ij} - S_i(X)\right)^k$

for all *i* = 1, ..., *p*.

Vector of sample excess kurtosis values

$B(X) = \left(B_1(X), ..., B_p(X)\right)$ with $B_i(X) = \frac{C_i^{(4)}(X)}{V_i^2(X)} - 3$

for all *i* = 1, ..., *p*.

Vector of sample skewness values

$\Gamma(X) = \left(\Gamma_1(X), ..., \Gamma_p(X)\right)$ with $\Gamma_i(X) = \frac{C_i^{(3)}(X)}{V_i^{1.5}(X)}$

for all *i* = 1, ..., *p*.

Vector of sample variation coefficients

$VC(X) = \left(VC_1(X), ..., VC_p(X)\right)$ with $VC_i(X) = \frac{V_i^{0.5}(X)}{M_i(X)}$

for all *i* = 1, ..., *p*.

Matrix of order statistics

Matrix $Y = (y_{ij})_{pxn}$, in which the *i*-th row $(Y)_i = (y_{ij})_{j=1..n}$ is obtained as a result of sorting in the ascending order of row $(X)_i = (x_{ij})_{j=1..n}$ in the original matrix of observations.

Vector of sample minimum values

$Min(X) = \left(Min_1(X), ..., Min_p(X)\right)$, where $Min_i(X) = y_{i1}$

for all *i* = 1, ..., *p*.

Vector of sample maximum values

$Max(X) = \left(Max_1(X), ..., Max_p(X)\right)$, where $Max_i(X) = y_{in}$

for all *i* = 1, ..., *p*.

Vector of sample median values

$Med(X) = \left(Med_1(X), ..., Med_p(X)\right)$, where $Med_i(X) = \begin{cases} y_{i,(n+1)/2}, \text{if } n \text{ is odd} \\ \left(y_{i,n/2} + y_{i,n/2+1}\right)/2, \text{if } n \text{ is even} \end{cases}$

for all *i* = 1, ..., *p*.

Vector of sample median absolute deviations

$MDAD(X) = \left(MDAD_1(X), ..., MDAD_p(X)\right)$, where $MDAD_i(X) = Med_i(Z)$ with $Z = \left(z_{ij}\right)_{i=1...p, j=1...n}$, $z_{ij} = \left|x_{ij} - Med_i(X)\right|$

for all *i* = 1, ..., *p*.

Vector of sample mean absolute deviations

$MNAD(X) = \left(MNAD_1(X), ..., MNAD_p(X)\right)$, where $MNAD_i(X) = M_i(Z)$ with $Z = \left(z_{ij}\right)_{i=1...p, j=1...n}$, $z_{ij} = \left|x_{ij} - M_i(X)\right|$

for all *i* = 1, ..., *p*.

Vector of sample quantile values

For a positive integer number *q* and *k* belonging to the interval [0, *q*-1], point z_i is the *k*-th *q* quantile of the random variable ξ_i if $P\{\xi_i \le z_i\} \ge \beta$ and $P\{\xi_i \le z_i\} \ge 1 - \beta$, where

- *P* is the probability measure.
- $\beta = k/n$ is the quantile order.

The calculation of quantiles is as follows:

j = [(*n*-1)β] and *f* = {(*n*-1)β} as integer and fractional parts of the number (*n*-1)β, respectively, and the vector of sample quantile values is

$Q(X,\beta) = (Q_1(X,\beta), \ldots, Q_p(X,\beta))$

where

$(Q_i(X,\beta) = y_{i,j+1} + f(y_{i,j+2} - y_{i,j+1})$

for all *i* = 1, ..., *p*.

Variance-covariance matrix

$C(X) = (c_{ij}(X))_{p \times p}$

where

$$c_{ij}(X) = \frac{1}{B}\sum_{k=1}^{n} w_k\left(x_{ik} - M_i(X)\right)\left(x_{jk} - M_j(X)\right),\ B = W - \sum_{j=1}^{n} w_j^2 / W$$

Cross-product matrix (matrix of cross-products and sums of squares)

$CP(X) = (cp_{ij}(X))_{p \times p}$

where

$$cp_{ij}(X) = \sum_{k=1}^{n} w_k\left(x_{ik} - M_i(X)\right)\left(x_{jk} - M_j(X)\right)$$

Pooled and group variance-covariance matrices

The set *N* = {1, ..., *n*} is partitioned into non-intersecting subsets

$$G_i,\ i = 1..g,\ N = \bigcup_{i=1}^{g} G_i$$

The observation $[X]_j = (x_{ij})_{i=1..p}$ belongs to the group *r* if *j*∈*G*$_r$. One observation belongs to one group only. The group mean and variance-covariance matrices are calculated similarly to the formulas above:

$$M^{(r)}(X) = \left(M_1^{(r)}(X), \ldots, M_p^{(r)}(X)\right) \text{ with } M_i^{(r)}(X) = \frac{1}{W^{(r)}}\sum_{j \in G_r} w_j x_{ij},\ W^{(r)} = \sum_{j \in G_r} w_j$$

for all *i* = 1, ..., *p*,

$$C^{(r)}(X) = \left(c_{ij}^{(r)}(X)\right)_{p \times p}$$

where

$$c_{ij}^{(r)}(X) = \frac{1}{B^{(r)}}\sum_{k \in G_r} w_k\left(x_{ik} - M_i^{(r)}(X)\right)\left(x_{jk} - M_j^{(r)}(X)\right),\ B^{(r)} = W^{(r)} - \sum_{j \in G_r} w_j^2 / W^{(r)}$$

for all *i* = 1, ..., *p* and *j* = 1, ..., *p*.

A pooled variance-covariance matrix and a pooled mean are computed as weighted mean over group covariance matrices and group means, correspondingly:

$$M^{pooled}(X) = \left(M_1^{pooled}(X), \ldots, M_p^{pooled}(X)\right) \text{ with } M_i^{pooled}(X) = \frac{1}{W^{(1)} + \ldots + W^{(g)}}\sum_{r=1}^{g} W^{(r)} M_i^{(r)}(X)$$

for all *i* = 1, ..., *p*,

$C^{pooled}\left(X\right) = \left(c_{ij}^{pooled}(X)\right)_{p \times p}$, $c_{ij}^{pooled}(X) = \frac{1}{B^{(1)} + \ldots + B^{(g)}} \sum_{r=1}^{g} B^{(r)} c_{ij}^{(r)}(X)$

for all i = 1, ..., p and j = 1, ..., p.

Correlation matrix

$R(X) = \left(r_{ij}(X)\right)_{p \times p}$, where $r_{ij}\left(X\right) = \frac{c_{ij}}{\sqrt{c_{ii}c_{jj}}}$

for all i = 1, ..., p and j = 1, ..., p.

Partial variance-covariance matrix

For a random vector ξ partitioned into two components Z and Y, a variance-covariance matrix C describes the structure of dependencies in the vector ξ:

$$C(X) = \begin{pmatrix} C_Z(X) & C_{ZY}(X) \\ C_{YZ}(X) & C_Y(X) \end{pmatrix}.$$

The partial covariance matrix $P(X) = (p_{ij}(X))_{kxk}$ is defined as

$P\left(X\right) = C_Y\left(X\right) - C_{YZ}\left(X\right)C_Z^{-1}C_{ZY}(X).$

where k is the dimension of Y.

Partial correlation matrix

The following is a partial correlation matrix for all i = 1, ..., k and j = 1, ..., k:

$RP(X) = \left(rp_{ij}(X)\right)_{k \times k}$, where $rp_{ij}(X) = \frac{p_{ij}(X)}{\sqrt{p_{ii}(X)p_{jj}(X)}}$

where

- k is the dimension of Y.
- $p_{ij}(X)$ are elements of the partial variance-covariance matrix.

Sorted dataset

Matrix $Y = (y_{ij})_{pxn}$, in which the i-th row $(Y)_i$ is obtained as a result of sorting in ascending order the row $(X)_i = (x_{ij})_{j = 1..n}$ in the original matrix of observations.

Fourier Transform Functions

The general form of the discrete Fourier transform is

$$z_{k_1,\, k_2,\, \ldots,\, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \ldots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \ldots, j_d} \exp\left(\delta i 2\pi \sum_{l=1}^{d} j_l k_l / n_l\right)$$

for $k_l = 0, \ldots n_l-1$ (l = 1, ..., d), where σ is a scale factor, δ = -1 for the forward transform, and δ = +1 for the inverse (backward) transform. In the forward transform, the input (periodic) sequence $\{w_{j_1, j_2, \ldots, j_d}\}$ belongs to the set of complex-valued sequences and real-valued sequences. Respective domains for the backward transform are represented by complex-valued sequences and complex-valued conjugate-even sequences.

The Intel® oneAPI Math Kernel Library (oneMKL) provides an interface for computing a discrete Fourier transform through the fast Fourier transform algorithm. Prefixes `Dfti` in function names and `DFTI` in the names of configuration parameters stand for Discrete Fourier Transform Interface.

The manual describes the following implementations of the fast Fourier transform functions available in Intel® oneAPI Math Kernel Library (oneMKL):

- Fast Fourier transform (FFT) functions for single-processor or shared-memory systems (see FFT Functions)
- Cluster FFT functions for distributed-memory architectures (available only for Intel® 64 architectures)

NOTE
Intel® oneAPI Math Kernel Library (oneMKL) also supports the FFTW3* interfaces to the fast Fourier transform functionality for shared memory paradigm (SMP) systems.

Both FFT and Cluster FFT functions compute an FFT in five steps:

1. Allocate a fresh descriptor for the problem with a call to the `DftiCreateDescriptor` or `DftiCreateDescriptorDM` function. The descriptor captures the configuration of the transform, such as the dimensionality (or rank), sizes, number of transforms, memory layout of the input/output data (defined by strides), and scaling factors. Many of the configuration settings are assigned default values in this call which you might need to modify in your application.
2. Optionally adjust the descriptor configuration with a call to the `DftiSetValue` or `DftiSetValueDM` function as needed. Typically, you must carefully define the data storage layout for an FFT or the data distribution among processes for a Cluster FFT. The configuration settings of the descriptor, such as the default values, can be obtained with the `DftiGetValue` or `DftiGetValueDM` function.
3. Commit the descriptor with a call to the `DftiCommitDescriptor` or `DftiCommitDescriptorDM` function, that is, make the descriptor ready for the transform computation. Once the descriptor is committed, the parameters of the transform, such as the type and number of transforms, strides and distances, the type and storage layout of the data, and so on, are "frozen" in the descriptor.
4. Compute the transform with a call to the `DftiComputeForward`/`DftiComputeBackward` or `DftiComputeForwardDM`/`DftiComputeBackwardDM` functions as many times as needed. Because the descriptor is defined and committed separately, all that the compute functions do is take the input and output data and compute the transform as defined. To modify any configuration parameters for another call to a compute function, use `DftiSetValue` followed by `DftiCommitDescriptor` (`DftiSetValueDM` followed by `DftiCommitDescriptorDM`) or create and commit another descriptor.
5. Deallocate the descriptor with a call to the `DftiFreeDescriptor` or `DftiFreeDescriptorDM` function. This returns the memory internally consumed by the descriptor to the operating system.

All the above functions return an integer status value, which is zero upon successful completion of the operation. You can interpret a non-zero status with the help of the `DftiErrorClass` or `DftiErrorMessage` function.

The FFT functions support lengths with arbitrary factors. You can improve performance of the Intel® oneAPI Math Kernel Library (oneMKL) FFT if the length of your data vector permits factorization into powers of optimized radices. See the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for specific radices supported efficiently.

NOTE
The FFT functions assume the Cartesian representation of complex data (that is, the real and imaginary parts define a complex number). The Intel® oneAPI Math Kernel Library (oneMKL) Vector Mathematical Functions provide efficient tools for conversion to and from polar representation (see Example "Conversion from Cartesian to polar representation of complex data" and Example "Conversion from polar to Cartesian representation of complex data").

FFT Functions

The fast Fourier transform function library of Intel® oneAPI Math Kernel Library (oneMKL) provides one-dimensional, two-dimensional, and multi-dimensional transforms (of up to seven dimensions) and offers both Fortran and C interfaces for all transform functions.

Table "FFT Functions in Intel® oneAPI Math Kernel Library (oneMKL)"lists FFT functions implemented in Intel® oneAPI Math Kernel Library (oneMKL):

FFT Functions in oneMKL

Function Name	Operation
Descriptor Manipulation Functions	
DftiCreateDescriptor	Allocates the descriptor data structure and initializes it with default configuration values.
DftiCommitDescriptor	Performs all initialization for the actual FFT computation.
DftiFreeDescriptor	Frees memory allocated for a descriptor.
DftiCopyDescriptor	Makes a copy of an existing descriptor.
FFT Computation Functions	
DftiComputeForward	Computes the forward FFT.
DftiComputeBackward	Computes the backward FFT.
Descriptor Configuration Functions	
DftiSetValue	Sets one particular configuration parameter with the specified configuration value.
DftiGetValue	Gets the value of one particular configuration parameter.
Status Checking Functions	
DftiErrorClass	Checks if the status reflects an error of a predefined class.
DftiErrorMessage	Translates the numeric value of an error status into a message.

FFT Interface

The Intel® oneAPI Math Kernel Library (oneMKL) FFT functions are provided with the Fortran and C interfaces.Fortran 95 is required because it offers features that have no counterpart in FORTRAN 77.

> **NOTE**
> The Fortran interface of the FFT computation functions requires one-dimensional data arrays for any dimension of FFT problem. For multidimensional transforms, pass the address of the first column of the multidimensional data to the computation functions.

To use the FFT functions, you need to access the module `MKL_DFTI` through the Fortran `use` statement.

The Fortran interface provides a derived type `DFTI_DESCRIPTOR`, named constants representing various names of configuration parameters and their possible values, and overloaded functions through the generic functionality of Fortran 95.

NOTE
The current version of the library may not support some of the FFT functions or functionality. You can find the complete list of the implementation-specific exceptions in the Intel® oneAPI Math Kernel Library (oneMKL) Release Notes.

For the main categories of Intel® oneAPI Math Kernel Library (oneMKL) FFT functions, see FFT Functions.

Computing an FFT

You can find code examples that compute transforms in the Fourier Transform Functions Code Examples.

Usually you can compute an FFT by five function calls (refer to the usage model for details). A single data structure, the descriptor, stores configuration parameters that can be changed independently.

The descriptor data structure, when created, contains information about the length and domain of the FFT to be computed, as well as the setting of several configuration parameters. Default settings for some of these parameters are as follows:

- Scale factor: none (that is, $\sigma = 1$)
- Number of data sets: one
- Data storage: contiguous
- Placement of results: in-place (the computed result overwrites the input data)

The default settings can be changed one at a time through the function `DftiSetValue` as illustrated in Example "Changing Default Settings (Fortran)".

Configuration Settings

Each of the configuration parameters is identified by a named constant in the `MKL_DFTI` module.

All the Intel® oneAPI Math Kernel Library (oneMKL) FFT configuration parameters are readable. Some of them are read-only, while others can be set using the `DftiCreateDescriptor` or `DftiSetValue` function.

Values of the configuration parameters fall into the following groups:

- Values that have native data types. For example, the number of simultaneous transforms requested has an integer value, while the scale factor for a forward transform is a floating-point number.
- Values that are discrete in nature and are provided in the `MKL_DFTI` module as named constants. For example, the domain of the forward transform requires values to be named constants.

The Table "Configuration Parameters" summarizes the information on configuration parameters, along with their types and values. For more details of each configuration parameter, see the subsection describing this parameter.

Configuration Parameters

Configuration Parameter	Type/Value	Comments
Most common configuration parameters, no default, must be set explicitly by `DftiCreateDescriptor`		
`DFTI_PRECISION`	Named constant `DFTI_SINGLE` or `DFTI_DOUBLE`	Precision of the computation.
`DFTI_FORWARD_DOMAIN`	Named constant `DFTI_COMPLEX` or `DFTI_REAL`	Type of the transform.
`DFTI_DIMENSION`	Integer scalar	Dimension of the transform.
`DFTI_LENGTHS`	Integer scalar/array	Lengths of each dimension.
Common configuration parameters, settable by `DftiSetValue`		

Configuration Parameter	Type/Value	Comments
DFTI_PLACEMENT	Named constant DFTI_INPLACE or DFTI_NOT_INPLACE	Defines whether the result overwrites the input data. Default value: DFTI_INPLACE.
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor for the forward transform. Default value: 1.0. Precision of the value should be the same as defined by DFTI_PRECISION.
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor for the backward transform. Default value: 1.0. Precision of the value should be the same as defined by DFTI_PRECISION.
DFTI_NUMBER_OF_USER_THREADS	Integer scalar	This configuration parameter is no longer used and kept for compatibility with previous versions of Intel® oneAPI Math Kernel Library (oneMKL).
DFTI_THREAD_LIMIT	Integer scalar	Limits the number of threads for the DftiComputeForward and DftiComputeBackward. Default value: 0.
DFTI_DESCRIPTOR_NAME	Character string	Assigns a name to a descriptor. Assumed length of the string is DFTI_MAX_NAME_LENGTH. Default value: empty string.
Data layout configuration parameters for single and multiple transforms. Settable by DftiSetValue		
DFTI_INPUT_STRIDES	Integer array	Defines the input data layout. **NOTE** The default strides are set during creation of the descriptor based on the desired dimension and lengths. For more details, see DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES.
DFTI_OUTPUT_STRIDES	Integer array	Defines the output data layout. **NOTE** The default strides are set during creation of the descriptor based on the desired dimension and lengths. For more details, see DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES.
DFTI_NUMBER_OF_TRANSFORMS	Integer scalar	Number of transforms. Default value: 1.
DFTI_INPUT_DISTANCE	Integer scalar	Defines the distance between input data sets for multiple transforms. Default value: 0.

Configuration Parameter	Type/Value	Comments
DFTI_OUTPUT_DISTANCE	Integer scalar	Defines the distance between output data sets for multiple transforms. Default value: 0.
DFTI_COMPLEX_STORAGE	Named constant DFTI_COMPLEX_COMPLEX or DFTI_REAL_REAL	Defines whether the real and imaginary parts of data for a complex transform are interleaved in one array or split in two arrays. Default value: DFTI_COMPLEX_COMPLEX.
DFTI_REAL_STORAGE	Named constant DFTI_REAL_REAL	Defines how real data for a real transform is stored. Only the DFTI_REAL_REAL value is supported.
DFTI_CONJUGATE_EVEN_STORAGE	Named constant DFTI_COMPLEX_COMPLEX or DFTI_COMPLEX_REAL	Defines whether the complex data in the backward domain of a real transform is stored as complex elements or as real elements. DFTI_COMPLEX_REAL is supported only for 1D transforms. The default value is DFTI_COMPLEX_COMPLEX.
DFTI_PACKED_FORMAT	Named constant DFTI_CCE_FORMAT, DFTI_CCS_FORMAT, DFTI_PACK_FORMAT, or DFTI_PERM_FORMAT	Defines the layout for the elements of the conjugate-even sequence in the backward domain of the real transform (in association with the configuration parameter DFTI_CONJUGATE_EVEN_STORAGE). The default value is DFTI_CCE_FORMAT. **NOTE** Transforms greater than 1D support only DFTI_CCE_FORMAT.
Advanced configuration parameters, settable by DftiSetValue		
DFTI_WORKSPACE	Named constant DFTI_ALLOW or DFTI_AVOID	Defines whether the library should prefer algorithms using additional memory. Default value: DFTI_ALLOW.
DFTI_ORDERING	Named constant DFTI_ORDERED or DFTI_BACKWARD_SCRAMBLED	Defines whether the result of a complex transform is ordered or permuted. Default value: DFTI_ORDERED.
Read-Only configuration parameters		
DFTI_COMMIT_STATUS	Named constant DFTI_UNCOMMITTED or DFTI_COMMITTED	Readiness of the descriptor for computation.
DFTI_VERSION	String	Version of Intel® oneAPI Math Kernel Library (oneMKL). Assumed length of the string is DFTI_VERSION_LENGTH.

Configuring and Computing an FFT in Fortran

DFTI_PRECISION

The configuration parameter `DFTI_PRECISION` denotes the floating-point precision in which the transform is to be carried out. A setting of `DFTI_SINGLE` stands for single precision, and a setting of `DFTI_DOUBLE` stands for double precision. The data must be presented in this precision, the computation is carried out in this precision, and the result is delivered in this precision.

`DFTI_PRECISION` does not have a default value. Set it explicitly by calling the `DftiCreateDescriptor` function.

> **NOTE**
> Fortran module `MKL_DFTI` also defines named constants `DFTI_SINGLE_R` and `DFTI_DOUBLE_R`, with the same semantics as `DFTI_SINGLE` and `DFTI_DOUBLE`, respectively. Do not use these constants to set the `DFTI_PRECISION` configuration parameter. Use them only as described in `DftiCreateDescriptor`.

To better understand configuration of the precision of transforms, refer to these examples in your Intel® oneAPI Math Kernel Library (oneMKL) directory:

```
./examples/dftf/source/basic_sp_complex_dft_1d.f90
```

```
./examples/dftf/source/basic_dp_complex_dft_1d.f90
```

`DFTI_FORWARD_DOMAIN`

`DFTI_DIMENSION, DFTI_LENGTHS`

`DftiCreateDescriptor`

DFTI_FORWARD_DOMAIN

The general form of a discrete Fourier transform is

$$z_{k_1,\,k_2,\ldots,\,k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \cdots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1,j_2,\ldots,\,j_d} \exp\left(\delta i 2\pi \sum_{l=1}^{d} j_l k_l / n_l\right)$$

for $k_l = 0, \ldots n_l-1$ (l = 1, ..., d), where σ is a scale factor, δ = -1 for the forward transform, and δ = +1 for the backward transform.

The Intel® oneAPI Math Kernel Library (oneMKL) implementation of the FFT algorithm, used for fast computation of discrete Fourier transforms, supports forward transforms on input sequences of two domains, as specified by the `DFTI_FORWARD_DOMAIN` configuration parameter: general complex-valued sequences (`DFTI_COMPLEX` domain) and general real-valued sequences (`DFTI_REAL` domain). The forward transform maps the forward domain to the corresponding backward domain, as shown in Table "Correspondence of Forward and Backward Domain".

The conjugate-even domain covers complex-valued sequences with the symmetry property:

$$x(k_1, k_2, \ldots, k_d) = conjugate(x(n_1 - k_1, n_2 - k_2, \ldots, n_d - k_d))$$

where the index arithmetic is performed modulo respective size, that is,

$$x(\ldots, expr_s, \ldots) \equiv x(\ldots, \mathrm{mod}(expr_s, n_s), \ldots),$$

and therefore

$$x(\ldots, n_s, \ldots) \equiv x(\ldots, 0, \ldots).$$

Due to this property of conjugate-even sequences, only a part of such sequence is stored in the computer memory, as described in `DFTI_CONJUGATE_EVEN_STORAGE`.

Correspondence of Forward and Backward Domain

Forward Domain	Implied Backward Domain
Complex (DFTI_COMPLEX)	Complex (DFTI_COMPLEX)
Real (DFTI_REAL)	Conjugate-even

DFTI_FORWARD_DOMAIN does not have a default value. Set it explicitly by calling the DftiCreateDescriptor function.

To better understand usage of the DFTI_FORWARD_DOMAIN configuration parameter, you can refer to these examples in your Intel® oneAPI Math Kernel Library (oneMKL) directory:

./examples/dftf/source/basic_sp_complex_dft_1d.f90

./examples/dftf/source/basic_sp_real_dft_1d.f90

DFTI_PRECISION

DFTI_DIMENSION, DFTI_LENGTHS

DftiCreateDescriptor

DFTI_DIMENSION, DFTI_LENGTHS

The dimension of the transform is a positive integer value represented in an integer scalar of Integer data type. For a one-dimensional transform, the transform length is specified by a positive integer value represented in an integer scalar of Integer data type. For multi-dimensional (≥ 2) transform, the lengths of each of the dimensions are supplied in an integer array (of Integer data type).

DFTI_DIMENSION and DFTI_LENGTHS do not have a default value. To set them, use the DftiCreateDescriptor function and not the DftiSetValue function.

To better understand usage of the DFTI_DIMENSION and DFTI_LENGTHS configuration parameters, you can refer to basic examples of one-, two-, and three-dimensional transforms in your Intel® oneAPI Math Kernel Library (oneMKL) directory. Naming conventions for the examples are self-explanatory. For example, refer to these examples of single-precision two-dimensional transforms:

./examples/dftf/source/basic_sp_real_dft_2d.f90

./examples/dftf/source/basic_sp_complex_dft_2d.f90

DftiSetValue

DFTI_FORWARD_SCALE, DFTI_BACKWARD_SCALE

The forward transform and backward transform are each associated with a scale factor σ of its own having the default value of 1. You can specify the scale factors using one or both of the configuration parameters DFTI_FORWARD_SCALE and DFTI_BACKWARD_SCALE. For example, for a one-dimensional transform of length *n*, you can use the default scale of 1 for the forward transform and set the scale factor for the backward transform to be 1/*n*, thus making the backward transform the inverse of the forward transform.

Set the scale factor configuration parameter using a real floating-point data type of the same precision as the value for DFTI_PRECISION.

DftiSetValue

DFTI_THREAD_LIMIT

In some situations you may need to limit the number of threads that the DftiComputeForward and DftiComputeBackward functions use. For example, if more than one thread calls Intel® oneAPI Math Kernel Library (oneMKL), it might be important that the thread calling these functions does not oversubscribe computing resources (CPU cores). Similarly, a known limit of the maximum number of threads to be used in computations might help the DftiCommitDescriptor function to select a more optimal computation method.

Set the parameter DFTI_THREAD_LIMIT as follows:

- To a positive number, to specify the maximum number of threads to be used by the compute functions.
- To zero (the default value), to use the maximum number of threads permitted in Intel® oneAPI Math Kernel Library (oneMKL) FFT functions. See "Techniques to Set the Number of Threads" in the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for more information.

On an attempt to set a negative value, the DftiSetValue function returns an error and does not update the descriptor.

The value of the DFTI_THREAD_LIMIT configuration parameter returned by the DftiGetValue function is defined as follows:

- 1 if Intel® oneAPI Math Kernel Library (oneMKL) runs in the sequential mode
- Depends of the commit status of the descriptor if Intel® oneAPI Math Kernel Library (oneMKL) runs in a threaded mode:

Commit Status	Value
Not committed	The value of DFTI_THREAD_LIMIT set in a previous call to the DftiSetValue function or the default value
Committed	The upper limit on the number of threads used by the DftiComputeForward and DftiComputeBackward functions

To better understand usage of the DFTI_THREAD_LIMIT configuration parameter, see this example in your Intel® oneAPI Math Kernel Library (oneMKL) directory:

```
./examples/dftf/source/config_thread_limit.f90
```

DFTI_COMMIT_STATUS

DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES

The FFT interface provides configuration parameters that define the layout of multidimensional data in the computer memory. For *d*-dimensional data set *X* defined by dimensions N_1 x N_2 x ... x N_d, the layout describes where a particular element $X(k_1, k_2, ..., k_d)$ of the data set is located. The memory address of the element $X(k_1, k_2 , ..., k_d)$ is expressed by the formula,

address of $X(k_1, k_2, ..., k_d)$ = the address stored in the pointer supplied to the compute function + (s_0 + $k_1*s_1 + k_2*s_2 + ...+ k_d*s_d$) * u,

Where u is the number of bytes per element of the desired precision for the assumed data type in the corresponding domain (see Table "Assumed Element Types of the Input/Output Data" below), where s_0 is the displacement, and s_1, ..., s_d are generalized strides. The configuration parameters DFTI_INPUT_STRIDES and DFTI_OUTPUT_STRIDES enable you to get and set these values. The configuration value is an array of values (s_0, s_1, ..., s_d) of INTEGER data type.

The DFTI_FORWARD_DOMAIN, DFTI_COMPLEX_STORAGE, and DFTI_CONJUGATE_EVEN_STORAGE configuration parameters define the type of the elements as shown in Table "Assumed Element Types of the Input/Output Data":

Assumed Element Types of the Input/Output Data

Descriptor Configuration	Element Type in the Forward Domain	Element Type in the Backward Domain
DFTI_FORWARD_DOMAIN=DFTI_COMPLEX DFTI_COMPLEX_STORAGE=DFTI_COMPLEX_COMPLEX	Complex	Complex
DFTI_FORWARD_DOMAIN=DFTI_COMPLEX DFTI_COMPLEX_STORAGE=DFTI_REAL_REAL	Real	Real
DFTI_FORWARD_DOMAIN=DFTI_REAL DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL	Real	Real
DFTI_FORWARD_DOMAIN=DFTI_REAL DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX	Real	Complex

The DFTI_INPUT_STRIDES configuration parameter defines the layout of the input data, while the element type is defined by the forward domain for the DftiComputeForward function and by the backward domain for the DftiComputeBackward function. The DFTI_OUTPUT_STRIDES configuration parameter defines the layout of the output data, while the element type is defined by the backward domain for the DftiComputeForward function and by the forward domain for DftiComputeBackward function.

NOTE
The DFTI_INPUT_STRIDES and DFTI_OUTPUT_STRIDES configuration parameters define the layout of input and output data, and not the forward-domain and backward-domain data. If the data layouts in forward domain and backward domain differ, set DFTI_INPUT_STRIDES and DFTI_OUTPUT_STRIDES explicitly and then commit the descriptor before calling computation functions.

For in-place transforms (DFTI_PLACEMENT=DFTI_INPLACE), the configuration set by DFTI_OUTPUT_STRIDES is ignored when the element types in the forward and backward domains are the same. If they are different, set DFTI_OUTPUT_STRIDES explicitly (even though the transform is in-place). Ensure a consistent configuration for in-place transforms, that is, the locations of the first elements on input and output must coincide in each dimension.

The FFT interface supports both positive and negative stride values. If you use negative strides, set the displacement of the data as follows:

$$s_0 = \sum_{i=1}^{d} (N_i - 1) \cdot \max(-s_i, 0).$$

The default setting of strides in a general multi-dimensional case assumes that the array that contains the data has no padding. The order of the strides depends on the programming language. For example:

```
INTEGER :: dims(d) = [n1, n2, …, nd]
status = DftiCreateDescriptor( hand, precision, domain, d, dims)
! The above call assumes data declaration:  type X(n1,n2,…,n_{d-1})
! Default strides are [ 0, 1, n1, n1*n2, …, n1*n2*…*n_{d-1}]
```

Note that in case of a real FFT (DFTI_FORWARD_DOMAIN=DFTI_REAL), where different data layouts in the backward domain are available (see DFTI_PACKED_FORMAT), the default value of the strides is not intuitive for the recommended CCE format (configuration setting DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX). In case of an *in-place* real transform with the CCE format, set the strides explicitly, as follows:

```
INTEGER :: dims(d) = [n1, n2, …, nd]
INTEGER :: rstrides(1+d) = [0, 1, 2*(n1/2+1), 2*(n1/2+1)*n2, …, 2*n_{d-1}*…*n_2*(n_1/2+1)]
INTEGER :: cstrides(1+d) = [0, 1, (n1/2+1), (n1/2+1)*n2, …, n_{d-1}*…*n_2*(n_1/2+1) ]
status = DftiCreateDescriptor( hand, precision, domain, d, dims)
status = DftiSetValue( hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
! Set the strides appropriately for forward/backward transform
```

Limitation Note Transforms with the number of points N of a non-unit stride dimension exceeding 2^(27−p) −1 for N a power-of-two, or 2^(23−p) − 1 for N not a power-of-two, are currently not supported, where p=0 for single precision and p=1 for double precision. If a descriptor is created (for example, using DftiCreateDescriptor) and set (for example, using DftiSetValue) to do such a transform, a DFTI_1D_MEMORY_EXCEEDS_INT32 error is returned at commit time (for example, by DftiCommitDescriptor).

DFTI_NUMBER_OF_TRANSFORMS

If you need to perform a large number of identical FFTs, you can do this in a single call to a DftiCompute* function with the value of the DFTI_NUMBER_OF_TRANSFORMS configuration parameter equal to the actual number of the transforms. The default value of this parameter is 1. You can set this parameter to a positive integer value of the Integer data type. When setting the number of transforms to a value greater than one, you also need to specify the distance between the input data sets and the distance between the output data sets using one of the DFTI_INPUT_DISTANCE and DFTI_OUTPUT_DISTANCE configuration parameters or both.

Important

- The data sets to be transformed must not have common elements.
- All the sets of data must be located within the same memory block.

To better understand usage of the DFTI_NUMBER_OF_TRANSFORMS configuration parameter, see this example in your Intel® oneAPI Math Kernel Library (oneMKL) directory:

```
./examples/dftf/source/config_number_of_transforms.f90
```

FFT Computation Functions

DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE

DftiSetValue

DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE

The FFT interface in Intel® oneAPI Math Kernel Library (oneMKL) enables computation of multiple transforms. To compute multiple transforms, you need to specify the data distribution of the multiple sets of data. The distance between the first data elements of consecutive data sets, DFTI_INPUT_DISTANCE for input data or DFTI_OUTPUT_DISTANCE for output data, specifies the distribution. The configuration setting is a value of INTEGER data type.

The default value for both configuration settings is one. You must set this parameter explicitly if the number of transforms is greater than one (see DFTI_NUMBER_OF_TRANSFORMS).

The distance is counted in elements of the data type defined by the descriptor configuration (rather than by the type of the variable passed to the computation functions). Specifically, the DFTI_FORWARD_DOMAIN, DFTI_COMPLEX_STORAGE, and DFTI_CONJUGATE_EVEN_STORAGE configuration parameters define the type of the elements as shown in Table "Assumed Element Types of the Input/Output Data".

NOTE
The configuration parameters DFTI_INPUT_DISTANCE and DFTI_OUTPUT_DISTANCE define the distance within input and output data, and not within the forward-domain and backward-domain data. If the distances in the forward and backward domains differ, set DFTI_INPUT_DISTANCE and DFTI_OUTPUT_DISTANCE explicitly and then commit the descriptor before calling computation functions.

For in-place transforms (DFTI_PLACEMENT=DFTI_INPLACE), the configuration set by DFTI_OUTPUT_DISTANCE is ignored when the element types in the forward and backward domains are the same. If they are different, set DFTI_OUTPUT_DISTANCE explicitly (even though the transform is in-place). Ensure a consistent configuration for in-place transforms, that is, the locations of the data sets on input and output must coincide.

This example illustrates setting of the DFTI_INPUT_DISTANCE configuration parameter:

```
INTEGER :: dims(d) = [n1, n2, …, nd]
INTEGER :: distance = n1*n2*…*nd
status = DftiCreateDescriptor( hand, precision, DFTI_COMPLEX, d, dims)
status = DftiSetValue( hand, DFTI_NUMBER_OF_TRANSFORMS, howmany )
status = DftiSetValue( hand, DFTI_INPUT_DISTANCE,  distance );
```

To better understand configuration of the distances, see these code examples in your Intel® oneAPI Math Kernel Library (oneMKL) directory:

./examples/dftf/source/config_number_of_transforms.f90

DFTI_COMPLEX_STORAGE, DFTI_REAL_STORAGE, DFTI_CONJUGATE_EVEN_STORAGE

Depending on the value of the DFTI_FORWARD_DOMAIN configuration parameter, the implementation of FFT supports several storage schemes for input and output data (see document [3] for the rationale behind the definition of the storage schemes). The data elements are placed within contiguous memory blocks, defined with generalized strides (see DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES). For multiple transforms, all sets of data should be located within the same memory block, and the data sets should be placed at the same distance from each other (see DFTI_NUMBER_OF_TRANSFORMS and DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE).

FFT Examples demonstrate the usage of storage formats.

DFTI_COMPLEX_STORAGE: storage schemes for a complex domain

For the DFTI_COMPLEX forward domain, both input and output sequences belong to a complex domain. In this case, the configuration parameter DFTI_COMPLEX_STORAGE can have one of the two values: DFTI_COMPLEX_COMPLEX (default) or DFTI_REAL_REAL.

NOTE
In the Intel® oneAPI Math Kernel Library (oneMKL)FFT interface, storage schemes for a forward complex domain and the respective backward complex domain are the same.

With DFTI_COMPLEX_COMPLEX storage, complex-valued data sequences are referenced by a single complex parameter (array) AZ so that a complex-valued element $z_{k_1, k_2, ..., k_d}$ of the m-th d-dimensional sequence is located at AZ[m*distance + stride$_0$ + k_1*stride$_1$ + k_2*stride$_2$+ ... k_d*stride$_d$] as a structure consisting of the real and imaginary parts.

This code illustrates the use of the DFTI_COMPLEX_COMPLEX storage:

```
complex :: AZ(N1,N2,N3,M)   ! sizes and number of transforms
...
! on input:  Z{k1,k2,k3,m} = AZ(k1,k2,k3,m)
status = DftiComputeForward( desc, AZ(:,1,1,1) )
! on output: Z{k1,k2,k3,m} = AZ(k1,k2,k3,m)
```

With the DFTI_REAL_REAL storage, complex-valued data sequences are referenced by two real parameters AR and AI so that a complex-valued element $z_{k_1, k_2, ..., k_d}$ of the m-th sequence is computed as AR[m*distance + stride$_0$ + k_1*stride$_1$ + k_2*stride$_2$+ ... k_d*stride$_d$] + √(-1) * AI[m*distance + stride$_0$ + k_1*stride$_1$ + k_2*stride$_2$+ ... k_d*stride$_d$].

This code illustrates the use of the DFTI_REAL_REAL storage:

```
real :: AR(N1,N2,N3,M), AI(N1,N2,N3,M)
...
! on input:  Z{k1,k2,k3,m} = cmplx(AR(k1,k2,k3,m),AI(k1,k2,k3,m))
status = DftiComputeForward( desc, AR(:,1,1,1), AI(:,1,1,1) )
! on output: Z{k1,k2,k3,m} = cmplx(AR(k1,k2,k3,m),AI(k1,k2,k3,m))
```

DFTI_REAL_STORAGE: storage schemes for a real domain

The Intel® oneAPI Math Kernel Library (oneMKL) FFT interface supports only one configuration value for this storage scheme: DFTI_REAL_REAL. With the DFTI_REAL_REAL storage, real-valued data sequences in a real domain are referenced by one real parameter AR so that real-valued element of the m-th sequence is located as AR[m*distance + stride$_0$ + k_1*stride$_1$ + k_2*stride$_2$+ ... k_d*stride$_d$].

DFTI_CONJUGATE_EVEN_STORAGE: storage scheme for a conjugate-even domain

The Intel® oneAPI Math Kernel Library (oneMKL) FFT interface supports two configuration values for this parameter: DFTI_COMPLEX_COMPLEX (default) and DFTI_COMPLEX_REAL (for 1D problems only). The conjugate-even symmetry of the data enables storing only about a half of the whole mathematical result, so that one part of it can be directly referenced in the memory while the other part can be reconstructed depending on the selected storage configuration.

With the DFTI_COMPLEX_COMPLEX storage, the complex-valued data sequences in the conjugate-even domain are referenced by one complex parameter AZ so that a complex-valued element $z_{k_1, k_2, ..., k_d}$ of the m-th sequence can be referenced or reconstructed as described below.

Consider a *d*-dimensional real-to-complex transform:

$$Z_{k_1,k_2,\ldots,k_d} \equiv \sum_{n_1=0}^{N_1-1} \cdots \sum_{n_d=0}^{N_d-1} R_{n_1,n_2,\ldots,n_d} e^{\frac{-2\pi i}{N_1} k_1 \cdot n_1} \cdots e^{\frac{-2\pi i}{N_d} k_d \cdot n_d}$$

Because the input sequence *R* is real-valued, the mathematical result *Z* has conjugate-even symmetry:

$z_{k_1, k_2, ..., k_d}$ = *conjugate* ($z_{N_1-k_1, N_2-k_2, ..., N_d-k_d}$),

where index arithmetic is performed modulo the length of the respective dimension. Obviously, the first element of the result is real-valued:

$z_{0, 0, ..., 0}$ = *conjugate* ($z_{0, 0, ..., 0}$).

For dimensions with even lengths, some of the other elements are real-valued too. For example, if N_s is even, $z_{0, 0, ..., N_s/2, 0, ..., 0} = conjugate\ (z_{0, 0, ..., N_s/2, 0, ..., 0})$.

With the conjugate-even symmetry, approximately a half of the result suffices to fully reconstruct it. For an arbitrary dimension h, it suffices to store elements $z_{k_1, ..., k_h, ..., k_d}$ for the following indices:

- $k_h = 0, ..., \lfloor N_h/2 \rfloor$
- $k_i = 0, ..., N_i - 1$, where $i = 1, ..., d$ and $i \neq h$

The symmetry property enables reconstructing the remaining elements: for $k_h = \lfloor N_h/2 \rfloor + 1, ..., N_h - 1$. In the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface, the halved dimension is the first dimension.

The following code illustrates usage of the DFTI_COMPLEX_COMPLEX storage for a conjugate-even domain:

```
real :: AR(N1,N2,M)          ! Array containing values of R
complex :: AZ(N1/2+1,N2,M)   ! Array containing values of Z
...
! on input:  R{k1,k2,m} = AR(k1,k2,m)
status = DftiComputeForward( desc, AR(:,1,1), AZ(:,1,1) )
! on output:
! for k1=1 … N1/2+1:  Z{k1,k2,m} = AZ(k1,k2,m)
! for k1=N1/2+2 … N1: Z{k1,k2,m} = conj(AZ(mod(N1-k1+1,N1)+1,mod(N2-k2+1,N2)+1,m))
```

For the backward transform, the input and output parameters and layouts exchange roles: set the strides describing the layout in the backward/forward domain as input/output strides, respectively. For example:

```
...
status = DftiSetValue( desc, DFTI_INPUT_STRIDES,  fwd_domain_strides )
status = DftiSetValue( desc, DFTI_OUTPUT_STRIDES, bwd_domain_strides )
status = DftiCommitDescriptor( desc )
status = DftiComputeForward( desc, ... )
...
status = DftiSetValue( desc, DFTI_INPUT_STRIDES,  bwd_domain_strides )
status = DftiSetValue( desc, DFTI_OUTPUT_STRIDES, fwd_domain_strides )
status = DftiCommitDescriptor( desc )
status = DftiComputeBackward( desc, ... )
```

Important
For in-place transforms, ensure the first element of the input data has the same location as the first element of the output data for each dimension.

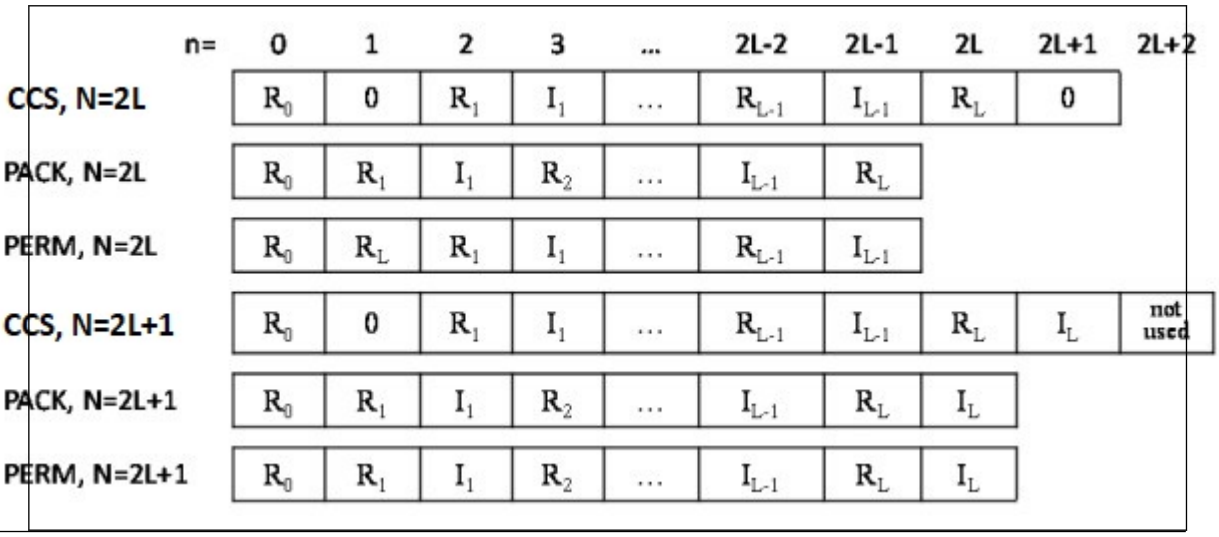
DFTI_PACKED_FORMAT

The result of the forward transform of real data is a conjugate-even sequence. Due to the symmetry property, only a part of the complex-valued sequence is stored in memory. The combination of the DFTI_PACKED_FORMAT and DFTI_CONJUGATE_EVEN_STORAGE configuration parameters defines how the conjugate-even sequence data is packed. If DFTI_CONJUGATE_EVEN_STORAGE is set to DFTI_COMPLEX_COMPLEX (default), the only possible value of DFTI_PACKED_FORMAT is DFTI_CCE_FORMAT; this association of configuration parameters is supported for transforms of any dimension. For a description of the corresponding packed format, see DFTI_CONJUGATE_EVEN_STORAGE. For one-dimensional transforms (only) with DFTI_CONJUGATE_EVEN_STORAGE set to DFTI_COMPLEX_REAL, the DFTI_PACKED_FORMAT configuration parameter must be DFTI_CCS_FORMAT, DFTI_PACK_FORMAT, or DFTI_PERM_FORMAT. The corresponding packed formats are explained and illustrated below.

DFTI_CCS_FORMAT for One-dimensional Transforms

The following figure illustrates the storage of a one-dimensional (1D) size-*N* conjugate-even sequence in a real array for the CCS, PACK, and PERM packed formats. The CCS format requires an array of size *N*+2, while the other formats require an array of size *N*. Zero-based indexing is used.

Storage of a 1D Size-*N* Conjugate-even Sequence in a Real Array



NOTE For storage of a one-dimensional conjugate-even sequence in a real array, CCS is in the same format as CCE.

The real and imaginary parts of the complex-valued conjugate-even sequence Z_k are located in a real-valued array `AC` as illustrated by figure "Storage of a 1D Size-*N* Conjugate-even Sequence in a Real Array" and can be used to reconstruct the whole conjugate-even sequence as follows:

```
real :: AR(N), AC(N+2)
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_CCS_FORMAT )
...
! on input:  R{k} = AR(k)
status = DftiComputeForward( desc, AR, AC )  ! real-to-complex FFT
! on output:
! for k=1 … N/2+1: Z{k} = cmplx( AC(1 + (2*(k-1)+0)),
!                                AC(1 + (2*(k-1)+1)) )
! for k=N/2+2 … N: Z{k} = cmplx( AC(1 + (2*mod(N-k+1,N)+0)),
!                               -AC(1 + (2*mod(N-k+1,N)+1)))
```

DFTI_PACK_FORMAT for One-dimensional Transforms

The real and imaginary parts of the complex-valued conjugate-even sequence Z_k are located in a real-valued array `AC` as illustrated by figure "Storage of a 1D Size-*N* Conjugate-even Sequence in a Real Array" and can be used to reconstruct the whole conjugate-even sequence as follows:

```
real :: AR(N), AC(N)
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_PACK_FORMAT )
...
! on input:  R{k} = AR(k)
status = DftiComputeForward( desc, AR, AC )  ! real-to-complex FFT
! on output: Z{k} = cmplx( re, im ), where
```

```
!  if (k == 1) then
!    re =  AC(1)
!    im =  0
!  else if (k-1 == N-k+1) then
!    re =  AC(2*(k-1))
!    im =  0
!  else if (k <= N/2+1) then
!    re =  AC(2*(k-1)+0)
!    im =  AC(2*(k-1)+1)
!  else
!    re =  AC(2*(N-k+1)+0)
!    im = -AC(2*(N-k+1)+1)
!  end if
```

DFTI_PERM_FORMAT for One-dimensional Transforms

The real and imaginary parts of the complex-valued conjugate-even sequence Z_k are located in real-valued array `AC` as illustrated by figure "Storage of a 1D Size-*N* Conjugate-even Sequence in a Real Array" and can be used to reconstruct the whole conjugate-even sequence as follows:

```
real :: AR(N), AC(N)
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_PERM_FORMAT )
...
! on input:  R{k} = AR(k)
status = DftiComputeForward( desc, AR, AC )  ! real-to-complex FFT
! on output: Z{k} = cmplx( re, im ), where
! if (k == 1) then
!   re =  AC(1)
!   im =  0
! else if (k-1 == N-k+1) then
!   re =  AC(2)
!   im =  0
! else if (k <= N/2+1) then
!   re =  AC(1+2*(k-1)+0-mod(N,2))
!   im =  AC(1+2*(k-1)+1-mod(N,2))
! else
!   re =  AC(1+2*(N-k+1)+0-mod(N,2))
!   im = -AC(1+2*(N-k+1)+1-mod(N,2))
! end if
```

DFTI_COMMIT_STATUS

The DFTI_COMMIT_STATUS configuration parameter indicates whether the descriptor is ready for computation. The parameter has two possible values:

DFTI_UNCOMMITTED	Default value, set after a successful call of DftiCreateDescriptor.
DFTI_COMMITTED	The value after a successful call to DftiCommitDescriptor.

A computation function called with an uncommitted descriptor returns an error.

You cannot directly set this configuration parameter in a call to DftiSetValue, but a change in the configuration of a committed descriptor may change the commit status of the descriptor to DFTI_UNCOMMITTED.

DFTI_ORDERING

Some FFT algorithms apply an explicit permutation stage that is time consuming [4]. The exclusion of this step is similar to applying an FFT to input data whose order is scrambled, or allowing a scrambled order of the FFT results. In applications such as convolution and power spectrum calculation, the order of result or data is unimportant and thus using scrambled data is acceptable if it leads to better performance. The following options are available in Intel® oneAPI Math Kernel Library (oneMKL):

- DFTI_ORDERED: Forward transform data ordered, backward transform data ordered (default option).
- DFTI_BACKWARD_SCRAMBLED: Forward transform data ordered, backward transform data scrambled.

Table "Scrambled Order Transform" tabulates the effect of this configuration setting.

Scrambled Order Transform

	DftiComputeForward	**DftiComputeBackward**
DFTI_ORDERING	Input → Output	Input → Output
DFTI_ORDERED	ordered → ordered	ordered → ordered
DFTI_BACKWARD_SCRAMBLED	ordered → scrambled	scrambled → ordered

NOTE
The word "scrambled" in this table means "permit scrambled order if possible". In some situations permitting out-of-order data gives no performance advantage and an implementation may choose to ignore the suggestion.

DftiSetValue

FFT Descriptor Manipulation Functions

This category contains the following functions: create a descriptor, commit a descriptor, copy a descriptor, and free a descriptor.

DftiCreateDescriptor

Allocates the descriptor data structure and initializes it with default configuration values.

Syntax

```
status = DftiCreateDescriptor( desc_handle, precision, forward_domain, dimension,
length )
```

Include Files

- mkl_dfti.f90

Input Parameters

Name	Type	Description
precision	INTEGER	Precision of the transform: DFTI_SINGLE or DFTI_DOUBLE.
forward_domain	INTEGER	Forward domain of the transform: DFTI_COMPLEX or DFTI_REAL.
dimension	INTEGER	Dimension of the transform.
length	INTEGER if *dimension* = 1. Array INTEGER, DIMENSION(*) otherwise.	Length of the transform for a one-dimensional transform. Lengths of each dimension for a multi-dimensional transform.

Output Parameters

Name	Type	Description
desc_handle	DFTI_DESCRIPTOR	FFT descriptor.
status	INTEGER	Function completion status.

Description

This function allocates memory for the descriptor data structure and instantiates it with all the default configuration settings for the precision, forward domain, dimension, and length of the desired transform. Because memory is allocated dynamically, the result is actually a pointer to the created descriptor. This function is slightly different from the "initialization" function that can be found in software packages or libraries that implement more traditional algorithms for computing an FFT. This function does not perform any significant computational work such as computation of twiddle factors. The function DftiCommitDescriptor does this work after the function DftiSetValue has set values of all necessary parameters.

The function returns zero when it completes successfully. See Status Checking Functions for more information on the returned status.

Interface

```
                ! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.

  INTERFACE DftiCreateDescriptor
```

```
    FUNCTION some_actual_function_1d(desc, precision, domain, dim, length)
      INTEGER :: some_actual_function_1d
      ...
      INTEGER, INTENT(IN) :: length
    END FUNCTION some_actual_function_1d

    FUNCTION some_actual_function_md(desc, precision, domain, dim, lengths)
      INTEGER :: some_actual_function_md
      ...
      INTEGER, INTENT(IN), DIMENSION(*) :: lengths
    END FUNCTION some_actual_function_md

    ...

END INTERFACE DftiCreateDescriptor
```

Note that the function is overloaded: the actual parameter for the formal parameter *length* can be a scalar or a rank-one array.

The function is also overloaded with respect to the type of the *precision* parameter in order to provide an option of using a precision-specific function for the generic name. Using more specific functions can reduce the size of statically linked executable for the applications using only single-precision FFTs or only double-precision FFTs. To use specific functions, change the "USE MKL_DFTI" statement in your program unit to one of the following:

```
USE MKL_DFTI, FORGET=>DFTI_SINGLE, DFTI_SINGLE=>DFTI_SINGLE_R
```

```
USE MKL_DFTI, FORGET=>DFTI_DOUBLE, DFTI_DOUBLE=>DFTI_DOUBLE_R
```

where the name "FORGET" can be replaced with any name that is not used in the program unit.

DftiCommitDescriptor

Performs all initialization for the actual FFT computation.

Syntax

status = DftiCommitDescriptor(*desc_handle*)

Include Files

- mkl_dfti.f90

Input Parameters

Name	Type	Description
desc_handle	DFTI_DESCRIPTOR	FFT descriptor.

Output Parameters

Name	Type	Description
desc_handle	DFTI_DESCRIPTOR	Updated FFT descriptor.
status	INTEGER	Function completion status.

Description

This function completes initialization of a previously created descriptor, which is required before the descriptor can be used for FFT computations. Typically, committing the descriptor performs all initialization that is required for the actual FFT computation. The initialization done by the function may involve exploring different factorizations of the input length to find the optimal computation method.

If you call the DftiSetValue function to change configuration parameters of a committed descriptor (see Descriptor Configuration Functions), you must re-commit the descriptor before invoking a computation function. Typically, a committal function call is immediately followed by a computation function call (see FFT Computation Functions).

The function returns zero when it completes successfully. See Status Checking Functions for more information on the returned status.

Interface

```
INTERFACE DftiCommitDescriptor
!Note that the body provided here is to illustrate the different
!argument list and types of dummy arguments. The interface
!does not guarantee what the actual function names are.
!Users can only rely on the function name following the
!keyword INTERFACE
 FUNCTION some_actual function_1 ( Desc_Handle )
 INTEGER :: some_actual function_1
 TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
 END FUNCTION some_actual function_1
END INTERFACE DftiCommitDescriptor
```

DftiFreeDescriptor

Frees the memory allocated for a descriptor.

Syntax

status = DftiFreeDescriptor(*desc_handle*)

Include Files

- mkl_dfti.f90

Input Parameters

Name	Type	Description
desc_handle	DESCRIPTOR_HANDLE	FFT descriptor.

Output Parameters

Name	Type	Description
desc_handle	DESCRIPTOR_HANDLE	Memory for the FFT descriptor is released.
status	INTEGER	Function completion status.

Description

This function frees all memory allocated for a descriptor.

> **NOTE**
> Memory allocation/deallocation inside Intel® oneAPI Math Kernel Library (oneMKL) is managed by Intel® oneAPI Math Kernel Library (oneMKL) memory management software. So, even after successful completion of `FreeDescriptor`, the memory space may continue being allocated for the application because the memory management software sometimes does not return the memory space to the OS, but considers the space free and can reuse it for future memory allocation. See Example mkl_free_buffers: Usage with FFT Functions on how to use Intel® oneAPI Math Kernel Library (oneMKL) memory management software and release memory to the OS.

The function returns zero when it completes successfully. See Status Checking Functions for more information on the returned status.

Interface

```
INTERFACE DftiFreeDescriptor
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
 FUNCTION some_actual_function_3( Desc_Handle )
 INTEGER :: some_actual_function_3
 TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
 END FUNCTION some_actual_function_3
END INTERFACE DftiFreeDescriptor
```

DftiCopyDescriptor

Makes a copy of an existing descriptor.

Syntax

status = DftiCopyDescriptor(*desc_handle_original*, *desc_handle_copy*)

Include Files

- mkl_dfti.f90

Input Parameters

Name	Type	Description
desc_handle_original	DESCRIPTOR_HANDLE	The FFT descriptor to copy.
	DESCRIPTOR_HANDLE	The FFT descriptor to copy.

Output Parameters

Name	Type	Description
dfti_handle_dst	DESCRIPTOR_HANDLE	The copy of the FFT descriptor.
status	INTEGER	Function completion status.

Description

This function makes a copy of an existing descriptor. The resulting descriptor *desc_handle_copy* and the existing descriptor *desc_handle_original* specify the same configuration of the transform, but do not have any memory areas in common ("deep copy").

The function returns zero when it completes successfully. See Status Checking Functions for more information on the returned status.

Interface

```
INTERFACE DftiCopyDescriptor
! Note that the body provided here is to illustrate the different
!argument list and types of dummy arguments. The interface
!does not guarantee what the actual function names are.
!Users can only rely on the function name following the
!keyword INTERFACE
 FUNCTION some_actual_function_2( Desc_Handle_Original,
 Desc_Handle_Copy )
 INTEGER :: some_actual_function_2
 TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Original, Desc_Handle_Copy
 END FUNCTION some_actual_function_2
END INTERFACE DftiCopyDescriptor
```

FFT Descriptor Configuration Functions

This category contains the following functions: the value setting function DftiSetValue sets one particular configuration parameter to an appropriate value, and the value-getting function DftiGetValue reads the value of one particular configuration parameter. While all configuration parameters are readable, you cannot set a few of them. Some of these contain fixed information of a particular implementation such as version number, or dynamic information, which is derived by the implementation during execution of one of the functions. See Configuration Settings for details.

DftiSetValue

Sets one particular configuration parameter with the specified configuration value.

Syntax

status = DftiSetValue(*desc_handle*, *config_param*, *config_val*)

Include Files

- mkl_dfti.f90

Input Parameters

Name	Type	Description
desc_handle	DFTI_DESCRIPTOR	FFT descriptor.
config_param	INTEGER	Configuration parameter.
config_val	Depends on the configuration parameter.	Configuration value.

Output Parameters

Name	Type	Description
desc_handle	DFTI_DESCRIPTOR	Updated FFT descriptor.
status	INTEGER	Function completion status.

Description

This function sets one particular configuration parameter with the specified configuration value. Each configuration parameter is a named constant, and the configuration value must have the corresponding type, which can be a named constant or a native type. For available configuration parameters and the corresponding configuration values, see:

- DFTI_PRECISION
- DFTI_FORWARD_DOMAIN
- DFTI_DIMENSION, DFTI_LENGTHS
- DFTI_PLACEMENT
- DFTI_FORWARD_SCALE, DFTI_BACKWARD_SCALE
- DFTI_THREAD_LIMIT
- DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES
- DFTI_NUMBER_OF_TRANSFORMS
- DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE
- DFTI_COMPLEX_STORAGE, DFTI_REAL_STORAGE, DFTI_CONJUGATE_EVEN_STORAGE
- DFTI_PACKED_FORMAT
- DFTI_WORKSPACE
- DFTI_ORDERING

You cannot use the DftiSetValue function to change configuration parameters DFTI_FORWARD_DOMAIN, DFTI_PRECISION, DFTI_DIMENSION, and DFTI_LENGTHS. Use the DftiCreateDescriptor function to set them.

Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in Configuring and Computing an FFT in Fortran .

The function returns zero when it completes successfully. See Status Checking Functions for more information on the returned status.

Interface

```
                INTERFACE DftiSetValue
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE

DftiCreateDescriptor

DftiGetValue

DftiGetValue

Gets the configuration value of one particular configuration parameter.

Syntax

status = DftiGetValue(*desc_handle*, *config_param*, *config_val*)

Include Files

- mkl_dfti.f90

Input Parameters

Name	Type	Description
desc_handle	DFTI_DESCRIPTOR	FFT descriptor.
config_param	INTEGER	Configuration parameter. See Table "Configuration Parameters" for allowable values of *config_param*.

Output Parameters

Name	Type	Description
config_val	Depends on the configuration parameter.	Configuration value.
status	INTEGER	Function completion status.

Description

This function gets the configuration value of one particular configuration parameter. Each configuration parameter is a named constant, and the configuration value must have the corresponding type, which can be a named constant or a native type. For available configuration parameters and the corresponding configuration values, see:

DftiSetValue

FFT Computation Functions

This category contains the following functions: compute the forward transform and compute the backward transform.

DftiComputeForward

Computes the forward FFT.

Syntax

status = DftiComputeForward(*desc_handle*, *x_inout*)

status = DftiComputeForward(*desc_handle*, *x_in*, *y_out*)

status = DftiComputeForward(*desc_handle*, *xre_inout*, *xim_inout*)

status = DftiComputeForward(*desc_handle*, *xre_in*, *xim_in*, *yre_out*, *yim_out*)

Input Parameters

Name	Type	Description
desc_handle	DFTI_DESCRIPTOR	FFT descriptor.
x_inout, x_in	Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor.	Data to be transformed in case of a real forward domain or, in the case of a complex forward domain in association with FTI_COMPLEX_COMPLEX, set for DFTI_COMPLEX_STORAGE.
xre_inout, xim_inout, xre_in, xim_in	Array REAL(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor.	Real and imaginary parts of the data to be transformed in the case of a complex forward domain.

The suffix in parameter names corresponds to the value of the configuration parameter DFTI_PLACEMENT as follows:

- *_inout* to DFTI_INPLACE
- *_in* to DFTI_NOT_INPLACE

Output Parameters

Name	Type	Description
y_out	Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor.	The transformed data in case of a real backward domain or, in the case of a complex forward domain in association with DFTI_COMPLEX_COMPLEX, set for DFTI_COMPLEX_STORAGE.
xre_inout, xim_inout, yre_out, yim_out	Array REAL(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor.	Real and imaginary parts of the transformed data in the case of a complex forward domain in association with DFTI_REAL_REAL set for DFTI_COMPLEX_STORAGE.
status	INTEGER	Function completion status.

The suffix in parameter names corresponds to the value of the configuration parameter DFTI_PLACEMENT as follows:

- *_inout* to DFTI_INPLACE
- *_out* to DFTI_NOT_INPLACE

Include Files

- mkl_dfti.f90

Description

The DftiComputeForward function accepts the descriptor handle parameter and one or more data parameters. Given a successfully configured and committed descriptor, this function computes the forward FFT, that is, the transform with the minus sign in the exponent, $\delta = -1$.

The DFTI_COMPLEX_STORAGE, DFTI_REAL_STORAGE, and DFTI_CONJUGATE_EVEN_STORAGE configuration parameters define the layout of the input and output data and must be properly set in a call to the DftiSetValue function. The forward domain and the precision of the transform are determined by the configuration settings DFTI_FORWARD_DOMAIN and DFTI_PRECISION, which are during construction of the descriptor.

The FFT descriptor must be properly configured prior to the function call. Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in Configuring and Computing an FFT in Fortran.

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by the generic interface. The generic Fortran interface to the computation functions is based on a set of specific functions. These functions can check for inconsistency between the required and actual number of parameters. However, the specific functions disregard the type of the actual parameters and instead use the interpretation defined in the descriptor by configuration parameters DFTI_FORWARD_DOMAIN, DFTI_INPUT_STRIDES, DFTI_INPUT_DISTANCE, and so on.

The function returns zero when it completes successfully. See Status Checking Functions for more information on the returned status.

Interface

```
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.
INTERFACE DftiComputeForward

  FUNCTION some_actual_function_1(desc,sSrcDst)
    INTEGER some_actual_function_1
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDst
    ...
  END FUNCTION some_actual_function_1

  FUNCTION some_actual_function_2(desc,cSrcDst)
    INTEGER some_actual_function_2
    COMPLEX(8), INTENT(INOUT), DIMENSION(*) :: cSrcDst
    ...
  END FUNCTION some_actual_function_2

  FUNCTION some_actual_function_3(desc,sSrcDstRe,sSrcDstIm)
    INTEGER some_actual_function_3
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstRe
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstIm
    ...
  END FUNCTION some_actual_function_3
  ...
END INTERFACE DftiComputeForward
```

The Fortran interface requires that the data parameters have the type of assumed-size rank-1 array, even for multidimensional transforms. The implementations of the FFT interface require the data stored linearly in memory with a regular stride pattern capable of describing multidimensional array layout (see also [3] and the more detailed discussion in DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES), and the function requires that the data parameters refer to the first element of the data. Consequently, the data arrays should be specified with the DIMENSION(*) attribute and the storage associated with the actual multidimensional arrays via the EQUIVALENCE statement.

status	INTEGER	Function completion status.

The suffix in parameter names corresponds to the value of the configuration parameter DFTI_PLACEMENT as follows:

- *_inout* to DFTI_INPLACE
- *_out* to DFTI_NOT_INPLACE

Include Files

- mkl_dfti.f90

Description

The function accepts the descriptor handle parameter and one or more data parameters. Given a successfully configured and committed descriptor, the DftiComputeBackward function computes the inverse FFT, that is, the transform with the plus sign in the exponent, $\delta = +1$.

The DFTI_COMPLEX_STORAGE, DFTI_REAL_STORAGE, and DFTI_CONJUGATE_EVEN_STORAGE configuration parameters define the layout of the input and output data and must be properly set in a call to the DftiSetValue function. The forward domain and the precision of the transform are determined by the configuration settings DFTI_FORWARD_DOMAIN and DFTI_PRECISION, which are during construction of the descriptor.

The FFT descriptor must be properly configured prior to the function call. Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in Configuring and Computing an FFT in Fortran.

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by the generic interface. The generic Fortran interface to the computation functions is based on a set of specific functions. These functions can check for inconsistency between the required and actual number of parameters. However, the specific functions disregard the type of the actual parameters and instead use the interpretation defined in the descriptor by configuration parameters DFTI_FORWARD_DOMAIN, DFTI_INPUT_STRIDES, DFTI_INPUT_DISTANCE, and so on.

The function returns zero when it completes successfully. See Status Checking Functions for more information on the returned status.

Interface

```
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
```

```
! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.
INTERFACE DftiComputeBackward

  FUNCTION some_actual_function_1(desc,sSrcDst)
    INTEGER some_actual_function_1
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDst
    ...
  END FUNCTION some_actual_function_1

  FUNCTION some_actual_function_2(desc,cSrcDst)
    INTEGER some_actual_function_2
    COMPLEX(8), INTENT(INOUT), DIMENSION(*) :: cSrcDst
    ...
  END FUNCTION some_actual_function_2

  FUNCTION some_actual_function_3(desc,sSrcDstRe,sSrcDstIm)
    INTEGER some_actual_function_3
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstRe
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstIm
    ...
  END FUNCTION some_actual_function_3

  ...
END INTERFACE DftiComputeBackward
```

The Fortran interface requires that the data parameters have the type of assumed-size rank-1 array, even for multidimensional transforms. The implementations of the FFT interface require the data stored linearly in memory with a regular stride pattern capable of describing multidimensional array layout (see also [3] and the more detailed discussion in `DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES`), and the function requires that the data parameters refer to the first element of the data. Consequently, the data arrays should be specified with the `DIMENSION(*)` attribute and the storage associated with the actual multidimensional arrays via the `EQUIVALENCE` statement.

You can find Fortran programs that illustrate configuring and computing FFTs in the `examples/dftf/` subdirectory of your Intel® oneAPI Math Kernel Library (oneMKL) directory.

Status Checking Functions

All of the descriptor manipulation, FFT computation, and descriptor configuration functions return an integer value denoting the status of the operation. The functions in this category check that status. The first function is a logical function that checks whether the status reflects an error of a predefined class, and the second is an error message function that returns a character string.

DftiErrorClass

Checks whether the status reflects an error of a predefined class.

Syntax

predicate = DftiErrorClass(*status*, *error_class*)

Include Files

- mkl_dfti.f90

Input Parameters

Name	Type	Description
status	INTEGER	Completion status of a fast Fourier transform (FFT) function.
error_class	INTEGER	Predefined error class.

Output Parameters

Name	Type	Description
predicate	LOGICAL	Result of checking.

Description

The FFT interface in Intel® oneAPI Math Kernel Library (oneMKL) provides a set of predefined error classeslisted in Table "Predefined Error Classes". They are named constants and have the type INTEGER.

Predefined Error Classes

Named Constants	Comments
DFTI_NO_ERROR	No error. The zero status belongs to this class.
DFTI_MEMORY_ERROR	Usually associated with memory allocation.
DFTI_INVALID_CONFIGURATION	Invalid settings in one or more configuration parameters.
DFTI_INCONSISTENT_CONFIGURATION	Inconsistent configuration or input parameters.
DFTI_NUMBER_OF_THREADS_ERROR	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function).
DFTI_MULTITHREADED_ERROR	Usually associated with a value that OMP routines return in case of errors.
DFTI_BAD_DESCRIPTOR	Descriptor is unusable for computation.
DFTI_UNIMPLEMENTED	Unimplemented legitimate settings; implementation dependent.
DFTI_MKL_INTERNAL_ERROR	Internal library error.
DFTI_1D_LENGTH_EXCEEDS_INT32	Length of one of the dimensions exceeds 2^{32} -1 (4 bytes).
DFTI_1D_MEMORY_EXCEEDS_INT32	Data size of one of the transforms exceeds 2^{31} -1 bytes.

NOTE
Use `DFTI_1D_MEMORY_EXCEEDS_INT32` instead of `DFTI_1D_LENGTH_EXCEEDS_INT32` for better accuracy.

The `DftiErrorClass` function returns the value of `.TRUE.` if the status belongs to the predefined error class. To check whether a function call was successful, call `DftiErrorClass` with a specific error class. However, the zero value of the status belongs to the `DFTI_NO_ERROR` class and thus the zero status indicates successful completion of an operation. See Example "Using Status Checking Functions" for an illustration of correct use of the status checking functions.

NOTE
It is incorrect to directly compare a status with a predefined class.

Interface

```
INTERFACE DftiErrorClass
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
 FUNCTION some_actual_function_8( Status, Error_Class )
 LOGICAL some_actual_function_8
 INTEGER, INTENT(IN) :: Status, Error_Class
 END FUNCTION some_actual_function_8
END INTERFACE DftiErrorClass
```

DftiErrorMessage

Generates an error message.

Syntax

error_message = DftiErrorMessage(*status*)

Include Files

- mkl_dfti.f90

Input Parameters

Name	Type	Description
status	INTEGER	Completion status of a function.

Output Parameters

Name	Type	Description
error_message	CHARACTER(LEN=DFTI_MAX_MESSAGE_LENGTH)	The character string with the error message.

Description

The error message function generates an error message character string. In Fortran, use a character string of length `DFTI_MAX_MESSAGE_LENGTH` as a target for the error message.

Example Using Status Checking Function shows how this function can be used.

Interface

```
INTERFACE DftiErrorMessage
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
 FUNCTION some_actual_function_9( Status )
 CHARACTER(LEN=DFTI_MAX_MESSAGE_LENGTH) some_actual_function_9( Status )
 INTEGER, INTENT(IN) :: Status
 END FUNCTION some_actual_function_9
END INTERFACE DftiErrorMessage
```

Cluster FFT Functions

This section describes the cluster Fast Fourier Transform (FFT) functions implemented in Intel® oneAPI Math Kernel Library (oneMKL).

> **NOTE**
> These functions are available only for Intel® 64 architectures.

The cluster FFT function library was designed to perform fast Fourier transforms on a cluster, that is, a group of computers interconnected via a network. Each computer (node) in the cluster has its own memory and processor(s). Data interchanges between the nodes are provided by the network.

One or more processes may be running in parallel on each cluster node. To organize communication between different processes, the cluster FFT function library uses the Message Passing Interface (MPI). To avoid dependence on a specific MPI implementation (for example, MPICH, Intel® MPI, and others), the library works with MPI via a message-passing library for linear algebra called BLACS.

Cluster FFT functions of Intel® oneAPI Math Kernel Library (oneMKL) provide one-dimensional, two-dimensional, and multi-dimensional (up to the order of 7) functions and both Fortran and C interfaces for all transform functions.

To develop applications using the cluster FFT functions, you should have basic skills in MPI programming.

The interfaces for the Intel® oneAPI Math Kernel Library (oneMKL) cluster FFT functions are similar to the corresponding interfaces for the conventional Intel® oneAPI Math Kernel Library (oneMKL)FFT functions. Refer there for details not explained in this section.

Table "Cluster FFT Functions in Intel® oneAPI Math Kernel Library (oneMKL)" lists cluster FFT functions implemented in Intel® oneAPI Math Kernel Library (oneMKL):

Cluster FFT Functions in oneMKL

Function Name	Operation
Descriptor Manipulation Functions	
`DftiCreateDescriptorDM`	Allocates memory for the descriptor data structure and preliminarily initializes it.

Function Name	Operation
DftiCommitDescriptorDM	Performs all initialization for the actual FFT computation.
DftiFreeDescriptorDM	Frees memory allocated for a descriptor.
FFT Computation Functions	
DftiComputeForwardDM	Computes the forward FFT.
DftiComputeBackwardDM	Computes the backward FFT.
Descriptor Configuration Functions	
DftiSetValueDM	Sets one particular configuration parameter with the specified configuration value.
DftiGetValueDM	Gets the value of one particular configuration parameter.

Computing Cluster FFT

The Intel® oneAPI Math Kernel Library (oneMKL)cluster FFT functions are provided with Fortran and C interfaces. Fortran stands for Fortran 95.

Cluster FFT computation is performed by DftiComputeForwardDM and DftiComputeBackwardDM functions, called in a program using MPI, which will be referred to as MPI program. After an MPI program starts, a number of processes are created. MPI identifies each process by its rank. The processes are independent of one another and communicate via MPI. A function called in an MPI program is invoked in all the processes. Each process manipulates data according to its rank. Input or output data for a cluster FFT transform is a sequence of real or complex values. A cluster FFT computation function operates on the local part of the input data, that is, some part of the data to be operated in a particular process, as well as generates local part of the output data. While each process performs its part of computations, running in parallel and communicating through MPI, the processes perform the entire FFT computation. FFT computations using the Intel® oneAPI Math Kernel Library (oneMKL) cluster FFT functions are typically effected by a number of steps listed below:

1. Initiate MPI by calling `MPI_INIT` (the function must be called prior to calling any FFT function and any MPI function).
2. Allocate memory for the descriptor and create it by calling DftiCreateDescriptorDM.
3. Specify one of several values of configuration parameters by one or more calls to DftiSetValueDM.
4. Obtain values of configuration parameters needed to create local data arrays; the values are retrieved by calling DftiGetValueDM.
5. Initialize the descriptor for the FFT computation by calling DftiCommitDescriptorDM.
6. Create arrays for local parts of input and output data and fill the local part of input data with values. (For more information, see Distributing Data among Processes.)
7. Compute the transform by calling DftiComputeForwardDM or DftiComputeBackwardDM.
8. Gather local output data into the global array using MPI functions. (This step is optional because you may need to immediately employ the data differently.)
9. Release memory allocated for the descriptor by calling DftiFreeDescriptorDM.
10. Finalize communication through MPI by calling `MPI_FINALIZE` (the function must be called after the last call to a cluster FFT function and the last call to an MPI function).

Several code examples in Examples for Cluster FFT Functions in the Code Examples appendix illustrate cluster FFT computations.

Distributing Data Among Processes

The Intel® oneAPI Math Kernel Library (oneMKL) cluster FFT functions store all input and output multi-dimensional arrays (matrices) in one-dimensional arrays (vectors). The arrays are stored in the column-major order. For example, a two-dimensional matrix `A` of size (*m*,*n*) is stored in a vector `B` of size *m***n* so that

`B((j-1)*m+i)=A(i,j)` (*i=1, ..., m, j=1, ..., n*) .

NOTE
Order of FFT dimensions is the same as the order of array dimensions in the programming language. For example, a 3-dimensional FFT with Lengths=(*m,n,l*) can be computed over an array `AR(m,n,l)`.

All MPI processes involved in cluster FFT computation operate their own portions of data. These local arrays make up the virtual global array that the fast Fourier transform is applied to. It is your responsibility to properly allocate local arrays (if needed), fill them with initial data and gather resulting data into an actual global array or process the resulting data differently. To be able do this, see sections below on how the virtual global array is composed of the local ones.

Multi-dimensional transforms

If the dimension of transform is greater than one, the cluster FFT function library splits data in the dimension whose index changes most slowly, so that the parts contain all elements with several consecutive values of this index. It is the first dimension in C and the last dimension in Fortran. If the global array is two-dimensional, in C, it gives each process several consecutive rows. The term "rows" will be used regardless of the array dimension and programming language. Local arrays are placed in memory allocated for the virtual global array consecutively, in the order determined by process ranks. For example, in case of two processes, during the computation of a three-dimensional transform whose matrix has size (11,15,12), the processes may store local arrays of sizes (6,15,12) and (5,15,12), respectively.

If *p* is the number of MPI processes and the matrix of a transform to be computed has size (*m,n,l*), in C, each MPI process works with local data array of size (m_q , *n, l*), where $\Sigma m_q=m$, *q=0, ... , p-1*. Local input arrays must contain appropriate parts of the actual global input array, and then local output arrays will contain appropriate parts of the actual global output array. You can figure out which particular rows of the global array the local array must contain from the following configuration parameters of the cluster FFT interface: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, and `CDFT_LOCAL_SIZE`. To retrieve values of the parameters, use the `DftiGetValueDM` function:

- `CDFT_LOCAL_NX` specifies how many rows of the global array the current process receives.
- `CDFT_LOCAL_START_X` specifies which row of the global input or output array corresponds to the first row of the local input or output array. If `A` is a global array and `L` is the appropriate local array, then

  `L(i,j,k)=A(i,j,k+cdft_local_start_x-1)`, where *i=1, ..., m, j=1, ..., n, k=1, ..., l_q*.

Example "2D Out-of-place Cluster FFT Computation" shows how the data is distributed among processes for a two-dimensional cluster FFT computation.

One-dimensional transforms

In this case, input and output data are distributed among processes differently and even the numbers of elements stored in a particular process before and after the transform may be different. Each local array stores a segment of consecutive elements of the appropriate global array. Such segment is determined by the number of elements and a shift with respect to the first array element. So, to specify segments of the global input and output arrays that a particular process receives, *four* configuration parameters are needed: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, `CDFT_LOCAL_OUT_NX`, and `CDFT_LOCAL_OUT_START_X`. Use the `DftiGetValueDM` function to retrieve their values. The meaning of the four configuration parameters depends upon the type of the transform, as shown in Table "Data Distribution Configuration Parameters for 1D Transforms":

Data Distribution Configuration Parameters for 1D Transforms

Meaning of the Parameter	Forward Transform	Backward Transform
Number of elements in input array	`CDFT_LOCAL_NX`	`CDFT_LOCAL_OUT_NX`

Meaning of the Parameter	Forward Transform	Backward Transform
Elements shift in input array	CDFT_LOCAL_START_X	CDFT_LOCAL_OUT_START_X
Number of elements in output array	CDFT_LOCAL_OUT_NX	CDFT_LOCAL_NX
Elements shift in output array	CDFT_LOCAL_OUT_START_X	CDFT_LOCAL_START_X

Memory size for local data

The memory size needed for local arrays cannot be just calculated from CDFT_LOCAL_NX (CDFT_LOCAL_OUT_NX), because the cluster FFT functions sometimes require allocating a little bit more memory for local data than just the size of the appropriate sub-array. The configuration parameter CDFT_LOCAL_SIZE specifies the size of the local input and output array in data elements. Each local input and output arrays must have size not less than CDFT_LOCAL_SIZE**size_of_element*. Note that in the current implementation of the cluster FFT interface, data elements can be real or complex values, each complex value consisting of the real and imaginary parts. If you employ a user-defined workspace for in-place transforms (for more information, refer to Table "Settable configuration Parameters"), it must have the same size as the local arrays. Example "1D In-place Cluster FFT Computations" illustrates how the cluster FFT functions distribute data among processes in case of a one-dimensional FFT computation performed with a user-defined workspace.

Available Auxiliary Functions

If a global input array is located on one MPI process and you want to obtain its local parts or you want to gather the global output array on one MPI process, you can use functions MKL_CDFT_ScatterData and MKL_CDFT_GatherData to distribute or gather data among processes, respectively. These functions are defined in a file that is delivered with Intel® oneAPI Math Kernel Library (oneMKL) and located in the following subdirectory of the Intel® oneAPI Math Kernel Library (oneMKL) installation directory: examples/cdftf/source/cdft_example_support.f90.

Restriction on Lengths of Transforms

The algorithm that the Intel® oneAPI Math Kernel Library (oneMKL) cluster FFT functions use to distribute data among processes imposes a restriction on lengths of transforms with respect to the number of MPI processes used for the FFT computation:

- For a multi-dimensional transform, the lengths of the last two dimensions must be not less than the number of MPI processes.
- The length of a one-dimensional transform must be the product of two integers each of which is not less than the number of MPI processes.

Non-compliance with the restriction causes an error CDFT_SPREAD_ERROR (refer to Error Codes for details). To achieve the compliance, you can change the transform lengths and/or the number of MPI processes, which is specified at start of an MPI program. MPI-2 enables changing the number of processes during execution of an MPI program.

Cluster FFT Interface

To use the cluster FFT functions, you need to access the module MKL_CDFT through the "use" statement.

The Fortran interface provides a derived type DFTI_DESCRIPTOR_DM; a number of named constants representing various names of configuration parameters and their possible values; and a number of overloaded functions through the generic functionality of Fortran 95.

To provide communication between parallel processes through MPI, the following include statement must be present in your code:

- Fortran:

  ```
  INCLUDE "mpif.h"
  ```

  (for some MPI versions, `"mpif90.h"` header may be used instead).

There are three main categories of the cluster FFT functions in Intel® oneAPI Math Kernel Library (oneMKL):

1. **Descriptor Manipulation**. There are three functions in this category. The `DftiCreateDescriptorDM` function creates an FFT descriptor whose storage is allocated dynamically. The `DftiCommitDescriptorDM` function "commits" the descriptor to all its settings. The `DftiFreeDescriptorDM` function frees up the memory allocated for the descriptor.
2. **FFT Computation**. There are two functions in this category. The `DftiComputeForwardDM` function performs the forward FFT computation, and the `DftiComputeBackwardDM` function performs the backward FFT computation.
3. **Descriptor Configuration**. There are two functions in this category. The `DftiSetValueDM` function sets one specific configuration value to one of the many configuration parameters. The `DftiGetValueDM` function gets the current value of any of these configuration parameters, all of which are readable. These parameters, though many, are handled one at a time.

Cluster FFT Descriptor Manipulation Functions

There are three functions in this category: create a descriptor, commit a descriptor, and free a descriptor.

DftiCreateDescriptorDM

Allocates memory for the descriptor data structure and preliminarily initializes it.

Syntax

```
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, size)
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, sizes)
```

Include Files

- `mkl_cdft.f90`

Input Parameters

comm	MPI communicator, e.g. `MPI_COMM_WORLD`.
v1	Precision of the transform.
v2	Type of the forward domain. Must be `DFTI_COMPLEX` for complex-to-complex transforms or `DFTI_REAL` for real-to-complex transforms.
dim	Dimension of the transform.
size	Length of the transform in a one-dimensional case.
sizes	Lengths of the transform in a multi-dimensional case.

Output Parameters

handle	Pointer to the descriptor handle of transform. If the function completes successfully, the pointer to the created handle is stored in the variable.

Description

This function allocates memory in a particular MPI process for the descriptor data structure and instantiates it with default configuration settings with respect to the precision, domain, dimension, and length of the desired transform. The domain is understood to be the domain of the forward transform. The result is a

pointer to the created descriptor. This function is slightly different from the "initialization" function DftiCommitDescriptorDM in a more traditional software packages or libraries used for computing the FFT. This function does not perform any significant computation work, such as twiddle factors computation, because the default configuration settings can still be changed using the function DftiSetValueDM.

The value of the parameter *v1* is specified through named constants DFTI_SINGLE and DFTI_DOUBLE. It corresponds to precision of input data, output data, and computation. A setting of DFTI_SINGLE indicates single-precision floating-point data type and a setting of DFTI_DOUBLE indicates double-precision floating-point data type.

The parameter *dim* is a simple positive integer indicating the dimension of the transform.

In Fortran, length is an integer or an array of integers.

Return Values

The function returns DFTI_NO_ERROR when completes successfully. In this case, the pointer to the created descriptor handle is stored in *handle*. If the function fails, it returns a value of another error class constant (for the list of constants, refer to Error Codes).

Interface

```
INTERFACE DftiCreateDescriptorDM
    INTEGER(4) FUNCTION DftiCreateDescriptorDMn(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L(*)
    END FUNCTION
    INTEGER(4) FUNCTION DftiCreateDescriptorDM1(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L
    END FUNCTION
END INTERFACE
```

DftiCommitDescriptorDM

Performs all initialization for the actual FFT computation.

Syntax

```
Status = DftiCommitDescriptorDM(handle)
```

Include Files

- mkl_cdft.f90

Input Parameters

handle	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM.

Description

The cluster FFT interface requires a function that completes initialization of a previously created descriptor before the descriptor can be used for FFT computations in a particular MPI process. The DftiCommitDescriptorDM function performs all initialization that facilitates the actual FFT computation. For the current implementation, it may involve exploring many different factorizations of the input length to search for a highly efficient computation method.

Any changes of configuration parameters of a committed descriptor via the set value function (see Descriptor Configuration Functions) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function is called right before a computation function call (see FFT Computation Functions).

Return Values

The function returns DFTI_NO_ERROR when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to Error Codes).

Interface

```
INTERFACE DftiCommitDescriptorDM
   INTEGER(4) FUNCTION DftiCommitDescriptorDM(handle);
     TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
 END FUNCTION
END INTERFACE
```

DftiFreeDescriptorDM

Frees memory allocated for a descriptor.

Syntax

Status = DftiFreeDescriptorDM(*handle*)

Include Files

- mkl_cdft.f90

Input Parameters

handle	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM.

Output Parameters

handle	The descriptor handle. Memory allocated for the handle is released on output.

Description

This function frees up all memory allocated for a descriptor in a particular MPI process. Call the DftiFreeDescriptorDM function to delete the descriptor handle. Upon successful completion of DftiFreeDescriptorDM the descriptor handle is no longer valid.

Return Values

The function returns DFTI_NO_ERROR when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to Error Codes).

Interface

```
INTERFACE DftiFreeDescriptorDM
 INTEGER(4) FUNCTION DftiFreeDescriptorDM(handle)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
```

```
   END FUNCTION
END INTERFACE
```

Cluster FFT Computation Functions

There are two functions in this category: compute the forward transform and compute the backward transform.

DftiComputeForwardDM

Computes the forward FFT.

Syntax

`Status = DftiComputeForwardDM(handle, in_X, out_X)`

`Status = DftiComputeForwardDM(handle, in_out_X)`

Include Files

- `mkl_cdft.f90`

Input Parameters

handle	The descriptor handle.
in_X, in_out_X	Local part of input data. Array of real or complex values (depending on the forward domain type). Refer to Distributing Data among Processes on how to allocate and initialize the array.

Output Parameters

out_X, in_out_X	Local part of output data. Array of complex values. Refer to Distributing Data among Processes on how to allocate the array.

Description

The `DftiComputeForwardDM` function computes the forward FFT. Forward FFT is the transform using the factor $e^{-i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by an internal call to the `DftiComputeForward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeForward`.

The local part of input data, as well as the local part of the output data, is an appropriate sequence of real or complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See Distributing Data Among Processes for details.

Refer to Configuration Settings for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter DFTI_PLACEMENT informs the function whether the computation should be in-place. If the value of this parameter is DFTI_INPLACE (default), you must call the function with two parameters, otherwise you must supply three parameters. If DFTI_PLACEMENT = DFTI_INPLACE and three parameters are supplied, then the third parameter is ignored.

Caution
Even in case of an out-of-place transform, local array of input data *in_X* may be changed. To save data, make its copy before calling DftiComputeForwardDM.

In case of an in-place transform, DftiComputeForwardDM dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE
You can specify your own workspace of the same size through the configuration parameter CDFT_WORKSPACE to avoid redundant memory allocation.

Return Values

The function returns DFTI_NO_ERROR when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to Error Codes).

Interface

```
INTERFACE DftiComputeForwardDM
   INTEGER(4) FUNCTION DftiComputeForwardDM(h, in_X, out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
   COMPLEX(8), DIMENSION(*) :: in_x, out_X
   END FUNCTION DftiComputeForwardDM
   INTEGER(4) FUNCTION DftiComputeForwardDMi(h, in_out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      COMPLEX(8), DIMENSION(*) :: in_out_X
   END FUNCTION DftiComputeForwardDMi
   INTEGER(4) FUNCTION DftiComputeForwardDMs(h, in_X, out_X)

   END FUNCTION DftiComputeForwardDMs
   INTEGER(4) FUNCTION DftiComputeForwardDMis(h, in_out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      COMPLEX(4), DIMENSION(*) :: in_out_X
   END FUNCTION DftiComputeForwardDMis
END INTERFACE
```

DftiComputeBackwardDM

Computes the backward FFT.

Syntax

```
Status = DftiComputeBackwardDM(handle, in_X, out_X)
```

```
Status = DftiComputeBackwardDM(handle, in_out_X)
```

Include Files

- mkl_cdft.f90

Input Parameters

handle	The descriptor handle.
in_X, in_out_X	Local part of input data. Array of complex values. Refer to Distributing Data among Processes on how to allocate and initialize the array.

Output Parameters

out_X, in_out_X	Local part of output data. Array of real or complex values (depending on the forward domain type. Refer to Distributing Data among Processes on how to allocate the array.

Description

The DftiComputeBackwardDM function computes the backward FFT. Backward FFT is the transform using the factor $e^{i2\pi/n}$.

Before you call the function, the valid descriptor, created by DftiCreateDescriptorDM, must be configured and committed using the DftiCommitDescriptorDM function.

The computation is carried out by an internal call to the DftiComputeBackward function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of DftiComputeBackward.

The local part of input data, as well as the local part of the output data, is an appropriate sequence of real or complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See Distributing Data among Processes for details.

Refer to Configuration Settings for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter DFTI_PRECISION determines the precision of input data, output data, and transform: a setting of DFTI_SINGLE indicates single-precision floating-point data type and a setting of DFTI_DOUBLE indicates double-precision floating-point data type.

The configuration parameter DFTI_PLACEMENT informs the function whether the computation should be in-place. If the value of this parameter is DFTI_INPLACE (default), you must call the function with two parameters, otherwise you must supply three parameters. If DFTI_PLACEMENT = DFTI_INPLACE and three parameters are supplied, then the third parameter is ignored.

Caution
Even in case of an out-of-place transform, local array of input data *in_X* may be changed. To save data, make its copy before calling DftiComputeBackwardDM.

In case of an in-place transform, DftiComputeBackwardDM dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE
You can specify your own workspace of the same size through the configuration parameter CDFT_WORKSPACE to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to Error Codes).

Interface

```
INTERFACE DftiComputeBackwardDM
   INTEGER(4) FUNCTION DftiComputeBackwardDM(h, in_X, out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      COMPLEX(8), DIMENSION(*) :: in_x, out_X
   END FUNCTION DftiComputeBackwardDM
   INTEGER(4) FUNCTION DftiComputeBackwardDMi(h, in_out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      COMPLEX(8), DIMENSION(*) :: in_out_X
   END FUNCTION DftiComputeBackwardDMi
   INTEGER(4) FUNCTION DftiComputeBackwardDMs(h, in_X, out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      COMPLEX(4), DIMENSION(*) :: in_x, out_X
   END FUNCTION DftiComputeBackwardDMs
   INTEGER(4) FUNCTION DftiComputeBackwardDMis(h, in_out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      COMPLEX(4), DIMENSION(*) :: in_out_X
   END FUNCTION DftiComputeBackwardDMis
END INTERFACE
```

Cluster FFT Descriptor Configuration Functions

There are two functions in this category: the value-setting function `DftiSetValueDM` sets one particular configuration parameter to an appropriate value, and the value-getting function `DftiGetValueDM` reads the value of one particular configuration parameter.

Some configuration parameters used by cluster FFT functions originate from the conventional FFT interface (see Configuration Settings for details).

Other configuration parameters are specific to the cluster FFT. Integer values of these parameters have type `INTEGER(4)`. The exact type of the configuration parameters being floating-point scalars is `REAL(4)` or `REAL(8)`. The configuration parameters whose values are named constants have the `INTEGER` type. They are defined in the `MKL_CDFT` module.

The names of the configuration parameters specific to the cluster FFT interface have the `CDFT` prefix.

DftiSetValueDM

Sets one particular configuration parameter with the specified configuration value.

Syntax

`Status = DftiSetValueDM (`*`handle`*`, `*`param`*`, `*`value`*`)`

Include Files

- `mkl_cdft.f90`

Input Parameters

`handle`	The descriptor handle. Must be valid, that is, created in a call to `DftiCreateDescriptorDM`.

param Name of a parameter to be set up in the descriptor handle. See Table "Settable Configuration Parameters" for the list of available parameters.

value Value of the parameter.

Description

This function sets one particular configuration parameter with the specified configuration value. The configuration parameter is one of the named constants listed in the table below, and the configuration value must have the corresponding type. See Configuration Settings for details of the meaning of each setting and for possible values of the parameters whose values are named constants.

Settable Configuration Parameters

Parameter Name	Data Type	Description	Default Value
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor of forward transform.	1.0
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor of backward transform.	1.0
DFTI_PLACEMENT	Named constant	Placement of the computation result.	DFTI_INPLACE
DFTI_ORDERING	Named constant	Scrambling of data order.	DFTI_ORDERED
CDFT_WORKSPACE	Array of an appropriate type	Auxiliary buffer, a user-defined workspace. Enables saving memory during in-place computations.	NULL (allocate workspace dynamically).
DFTI_PACKED_FORMAT	Named constant	Packed format for storing conjugate-even sequence (in the case of a real forward domain).	• DFTI_PERM_FORMAT — default and the only available value for one-dimensional transforms • DFTI_CCE_FORMAT — default and the only available value for multi-dimensional transforms
DFTI_TRANSPOSE	Named constant	This parameter determines how the output data is located for multi-dimensional transforms. If the parameter value is DFTI_NONE, the data is located in a usual manner described in this document. If the value is DFTI_ALLOW, the last (first) global transposition is not performed for a forward (backward) transform.	DFTI_NONE

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to Error Codes).

Interface

```
INTERFACE DftiSetValueDM
   INTEGER(4) FUNCTION DftiSetValueDM(h, p, v)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      INTEGER(4) :: p, v
   END FUNCTION
   INTEGER(4) FUNCTION DftiSetValueDMd(h, p, v)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      INTEGER(4) :: p
      REAL(8) :: v
   END FUNCTION
   INTEGER(4) FUNCTION DftiSetValueDMs(h, p, v)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      INTEGER(4) :: p
      REAL(4) :: v
   END FUNCTION
   INTEGER(4) FUNCTION DftiSetValueDMsw(h, p, v)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      INTEGER(4) :: p
      COMPLEX(4) :: v(*)
   END FUNCTION
   INTEGER(4) FUNCTION DftiSetValueDMdw(h, p, v)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      INTEGER(4) :: p
      COMPLEX(8) :: v(*)
   END FUNCTION
END INTERFACE
```

DftiGetValueDM

Gets the value of one particular configuration parameter.

Syntax

`Status = DftiGetValueDM(`*`handle`*`, `*`param`*`, `*`value`*`)`

Include Files

- `mkl_cdft.f90`

Input Parameters

`handle`	The descriptor handle. Must be valid, that is, created in a call to `DftiCreateDescriptorDM`.
`param`	Name of a parameter to be retrieved from the descriptor. See Table "Retrievable Configuration Parameters" for the list of available parameters.

Output Parameters

value	Value of the parameter.

Description

This function gets the configuration value of one particular configuration parameter. The configuration parameter is one of the named constants listed in the table below, and the configuration value is the corresponding appropriate type, which can be a named constant or a native type. Possible values of the named constants can be found in Table "Configuration Parameters" and relevant subsections of the Configuration Settings section.

Retrievable Configuration Parameters

Parameter Name	Data Type	Description
DFTI_PRECISION	Named constant	Precision of computation, input data and output data.
DFTI_DIMENSION	Integer scalar	Dimension of the transform
DFTI_LENGTHS	Array of integer values	Array of lengths of the transform. Number of lengths corresponds to the dimension of the transform.
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor of forward transform.
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor of backward transform.
DFTI_PLACEMENT	Named constant	Placement of the computation result.
DFTI_COMMIT_STATUS	Named constant	Shows whether descriptor has been committed.
DFTI_FORWARD_DOMAIN	Named constant	Forward domain of transforms, has the value of DFTI_COMPLEX or DFTI_REAL.
DFTI_ORDERING	Named constant	Scrambling of data order.
CDFT_MPI_COMM	Type of MPI communicator	MPI communicator used for transforms.
CDFT_LOCAL_SIZE	Integer scalar	Necessary size of input, output, and buffer arrays in data elements.
CDFT_LOCAL_X_START	Integer scalar	Row/element number of the global array that corresponds to the first row/element of the local array. For more information, see Distributing Data among Processes.
CDFT_LOCAL_NX	Integer scalar	The number of rows/elements of the global array stored in the local array. For more information, see Distributing Data among Processes.
CDFT_LOCAL_OUT_X_START	Integer scalar	Element number of the appropriate global array that corresponds to the first element of the input or output local array in a 1D case. For details, see Distributing Data among Processes.

Parameter Name	Data Type	Description
CDFT_LOCAL_OUT_NX	Integer scalar	The number of elements of the appropriate global array that are stored in the input or output local array in a 1D case. For details, see Distributing Data among Processes.

Return Values

The function returns DFTI_NO_ERROR when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to Error Codes).

Interface

```
INTERFACE DftiGetValueDM
   INTEGER(4) FUNCTION DftiGetValueDM(h, p, v)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      INTEGER(4) :: p, v
   END FUNCTION
   INTEGER(4) FUNCTION DftiGetValueDMar(h, p, v)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      INTEGER(4) :: p, v(*)
   END FUNCTION
   INTEGER(4) FUNCTION DftiGetValueDMd(h, p, v)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      INTEGER(4) :: p
      REAL(8) :: v
   END FUNCTION
   INTEGER(4) FUNCTION DftiGetValueDMs(h, p, v)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      INTEGER(4) :: p
      REAL(4) :: v
   END FUNCTION
END INTERFACE
```

Error Codes

All the cluster FFT functions return an integer value denoting the status of the operation. These values are identified by named constants. Each function returns DFTI_NO_ERROR if no errors were encountered during execution. Otherwise, a function generates an error code. In addition to FFT error codes, the cluster FFT interface has its own ones. The named constants specific to the cluster FFT interface have the CDFT prefix in their names. Table "Error Codes that Cluster FFT Functions Return" lists error codes that the cluster FFT functions may return.

Error Codes that Cluster FFT Functions Return

Named Constants	Comments
DFTI_NO_ERROR	No error.
DFTI_MEMORY_ERROR	Usually associated with memory allocation.
DFTI_INVALID_CONFIGURATION	Invalid settings of one or more configuration parameters.
DFTI_INCONSISTENT_CONFIGURATION	Inconsistent configuration or input parameters.

Named Constants	Comments
DFTI_NUMBER_OF_THREADS_ERROR	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function).
DFTI_MULTITHREADED_ERROR	Usually associated with a value that OMP routines return in case of errors.
DFTI_BAD_DESCRIPTOR	Descriptor is unusable for computation.
DFTI_UNIMPLEMENTED	Unimplemented legitimate settings; implementation dependent.
DFTI_MKL_INTERNAL_ERROR	Internal library error.
DFTI_1D_LENGTH_EXCEEDS_INT32	Length of one of the dimensions exceeds 2^{32} -1 (4 bytes).
CDFT_SPREAD_ERROR	Data cannot be distributed (For more information, see Distributing Data among Processes.)
CDFT_MPI_ERROR	MPI error. Occurs when calling MPI.

PBLAS Routines

Intel® oneAPI Math Kernel Libraryimplements the PBLAS (Parallel Basic Linear Algebra Subprograms) routines from the ScaLAPACK package for distributed-memory architecture. PBLAS is intended for using in vector-vector, matrix-vector, and matrix-matrix operations to simplify the parallelization of linear codes. The design of PBLAS is as consistent as possible with that of the BLAS. The routine descriptions are arranged in several sections according to the PBLAS level of operation:

- PBLAS Level 1 Routines (distributed vector-vector operations)
- PBLAS Level 2 Routines (distributed matrix-vector operations)
- PBLAS Level 3 Routines (distributed matrix-matrix operations)

Each section presents the routine and function group descriptions in alphabetical order by the routine group name; for example, the `p?asum` group, the `p?axpy` group. The question mark in the group name corresponds to a character indicating the data type (`s`, `d`, `c`, and `z` or their combination); see *Routine Naming Conventions*.

NOTE
PBLAS routines are provided only with Intel® oneAPI Math Kernel Library (oneMKL) versions for Linux* and Windows* OSs.

Generally, PBLAS runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of PBLAS optimized for the target architecture. The Intel® oneAPI Math Kernel Library (oneMKL) version of PBLAS is optimized for Intel® processors. For the detailed system and environment requirements see*Intel® oneAPI Math Kernel Library (oneMKL) Release Notes* and *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*.

For full reference on PBLAS routines and related information, see http://www.netlib.org/scalapack/html/pblas_qref.html.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

PBLAS Routines Overview

The model of the computing environment for PBLAS is represented as a one-dimensional array of processes or also a two-dimensional process grid. To use PBLAS, all global matrices or vectors must be distributed on this array or grid prior to calling the PBLAS routines.

PBLAS uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, as well as gives the opportunity to use PBLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global array and its corresponding process and memory location is contained in the so called *array descriptor* associated with each global array. Table "Content of the array descriptor for dense matrices" gives an example of an array descriptor structure.

Content of Array Descriptor for Dense Matrices

Array Element #	Name	Definition
1	*dtype*	Descriptor type (=1 for dense matrices)
2	*ctxt*	BLACS context handle for the process grid
3	*m*	Number of rows in the global array
4	*n*	Number of columns in the global array
5	*mb*	Row blocking factor
6	*nb*	Column blocking factor
7	*rsrc*	Process row over which the first row of the global array is distributed
8	*csrc*	Process column over which the first column of the global array is distributed
9	*lld*	Leading dimension of the local array

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by *LOCr*() and *LOCc*(), respectively. To compute these numbers, you can use the ScaLAPACK tool routine numroc.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix of the global matrix *A*, which is contained in the global subarray sub(*A*), defined by the following 6 values (for dense matrices):

m	The number of rows of sub(*A*)
n	The number of columns of sub(*A*)
a	A pointer to the local array containing the entire global array *A*
ia	The row index of sub(*A*) in the global array
ja	The column index of sub(*A*) in the global array
desca	The array descriptor for the global array *A*

Intel® oneAPI Math Kernel Library (oneMKL) provides the PBLAS routines with interface similar to the interface used in the Netlib PBLAS (see http://www.netlib.org/scalapack/html/pblas_qref.html).

PBLAS Routine Naming Conventions

The naming convention for PBLAS routines is similar to that used for BLAS routines (see Routine Naming Conventions). A general rule is that each routine name in PBLAS, which has a BLAS equivalent, is simply the BLAS name prefixed by initial letter p that stands for "parallel".

The Intel® oneAPI Math Kernel Library (oneMKL) PBLAS routine names have the following structure:

```
p <character> <name> <mod> ( )
```

The <*character*> field indicates the Fortran data type:

s	real, single precision
c	complex, single precision
d	real, double precision
z	complex, double precision
i	integer

Some routines and functions can have combined character codes, such as sc or dz.

For example, the function pscasum uses a complex input array and returns a real value.

The <*name*> field, in PBLAS level 1, indicates the operation type. For example, the PBLAS level 1 routines p?dot, p?swap, p?copy compute a vector dot product, vector swap, and a copy vector, respectively.

In PBLAS level 2 and 3, <*name*> reflects the matrix argument type:

ge	general matrix
sy	symmetric matrix
he	Hermitian matrix
tr	triangular matrix

In PBLAS level 3, the <*name*>=tran indicates the transposition of the matrix.

The <*mod*> field, if present, provides additional details of the operation. The PBLAS level 1 names can have the following characters in the <*mod*> field:

c	conjugated vector
u	unconjugated vector

The PBLAS level 2 names can have the following additional characters in the <*mod*> field:

mv	matrix-vector product
sv	solving a system of linear equations with matrix-vector operations
r	rank-1 update of a matrix
r2	rank-2 update of a matrix.

The PBLAS level 3 names can have the following additional characters in the <*mod*> field:

mm	matrix-matrix product
sm	solving a system of linear equations with matrix-matrix operations
rk	rank-*k* update of a matrix
r2k	rank-2*k* update of a matrix.

The examples below show how to interpret PBLAS routine names:

pddot	<p> <d> <dot>: double-precision real distributed vector-vector dot product
pcdotc	<p> <c> <dot> <c>: complex distributed vector-vector dot product, conjugated
pscasum	<p> <sc> <asum>: sum of magnitudes of distributed vector elements, single precision real output and single precision complex input
pcdotu	<p> <c> <dot> <u>: distributed vector-vector dot product, unconjugated, complex

psgemv	<p> <s> <ge> <mv>: distributed matrix-vector product, general matrix, single precision
pztrmm	<p> <z> <tr> <mm>: distributed matrix-matrix product, triangular matrix, double-precision complex.

PBLAS Level 1 Routines

PBLAS Level 1 includes routines and functions that perform distributed vector-vector operations. Table "PBLAS Level 1 Routine Groups and Their Data Types" lists the PBLAS Level 1 routine groups and the data types associated with them.

PBLAS Level 1 Routine Groups and Their Data Types

Routine or Function Group	Data Types	Description
p?amax	s, d, c, z	Calculates an index of the distributed vector element with maximum absolute value
p?asum	s, d, sc, dz	Calculates sum of magnitudes of a distributed vector
p?axpy	s, d, c, z	Calculates distributed vector-scalar product
p?copy	s, d, c, z	Copies a distributed vector
p?dot	s, d	Calculates a dot product of two distributed real vectors
p?dotc	c, z	Calculates a dot product of two distributed complex vectors, one of them is conjugated
p?dotu	c, z	Calculates a dot product of two distributed complex vectors
p?nrm2	s, d, sc, dz	Calculates the 2-norm (Euclidean norm) of a distributed vector
p?scal	s, d, c, z, cs, zd	Calculates a product of a distributed vector by a scalar
p?swap	s, d, c, z	Swaps two distributed vectors

p?amax

Computes the global index of the element of a distributed vector with maximum absolute value.

Syntax

```
call psamax(n, amax, indx, x, ix, jx, descx, incx)
call pdamax(n, amax, indx, x, ix, jx, descx, incx)
call pcamax(n, amax, indx, x, ix, jx, descx, incx)
call pzamax(n, amax, indx, x, ix, jx, descx, incx)
```

Include Files

- mkl_pblas.h

Description

The functions p?amax compute global index of the maximum element in absolute value of a distributed vector sub(*x*),

where sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1.

Input Parameters

n	(global) INTEGER. The length of distributed vector sub(*x*), *n*≥0.
x	(local) REAL for psamax DOUBLE PRECISION for pdamax COMPLEX for pcamax DOUBLE COMPLEX for pzamax Array, size (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.
descx	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

amax	(global)REAL for psamax. DOUBLE PRECISION for pdamax. COMPLEX for pcamax. DOUBLE COMPLEX for pzamax. Maximum absolute value (magnitude) of elements of the distributed vector only in its scope.
indx	(global) INTEGER. The global index of the maximum element in absolute value of the distributed vector sub(*x*) only in its scope.

p?asum

Computes the sum of magnitudes of elements of a distributed vector.

Syntax

```
call psasum(n, asum, x, ix, jx, descx, incx)
call pscasum(n, asum, x, ix, jx, descx, incx)
```

```
call pdasum(n, asum, x, ix, jx, descx, incx)
call pdzasum(n, asum, x, ix, jx, descx, incx)
```

Include Files

- mkl_pblas.h

Description

The functions p?asum compute the sum of the magnitudes of elements of a distributed vector sub(*x*), where sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1.

Input Parameters

n	(global) INTEGER. The length of distributed vector sub(*x*), *n*≥0.
x	(local) REAL for psasum DOUBLE PRECISION for pdasum COMPLEX for pscasum DOUBLE COMPLEX for pdzasum Array, size (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.
descx	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

asum	(local) REAL for psasum and pscasum. DOUBLE PRECISION for pdasum and pdzasum Contains the sum of magnitudes of elements of the distributed vector only in its scope.

p?axpy

Computes a distributed vector-scalar product and adds the result to a distributed vector.

Syntax

```
call psaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pcaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- mkl_pblas.h

Description

The p?axpy routines perform the following operation with distributed vectors:

```
sub(y) := sub(y) + a*sub(x)
```

where:

a is a scalar;

sub(*x*) and sub(*y*) are *n*-element distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1;

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy*=*m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy*= 1.

Input Parameters

n	(global) INTEGER. The length of distributed vectors, *n*≥0.
a	(local) REAL for psaxpy DOUBLE PRECISION for pdaxpy COMPLEX for pcaxpy DOUBLE COMPLEX for pzaxpy Specifies the scalar *a*.
x	(local) REAL for psaxpy DOUBLE PRECISION for pdaxpy COMPLEX for pcaxpy DOUBLE COMPLEX for pzaxpy Array, size (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.
descx	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
y	(local) REAL for psaxpy DOUBLE PRECISION for pdaxpy COMPLEX for pcaxpy DOUBLE COMPLEX for pzaxpy Array, size (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).

iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*Y*), respectively.
descy	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y	Overwritten by sub(*y*) := sub(*y*) + *a**sub(*x*).

p?copy

Copies one distributed vector to another vector.

Syntax

```
call pscopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdcopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pccopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzcopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call picopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- mkl_pblas.h

Description

The p?copy routines perform a copy operation with distributed vectors defined as

```
sub(y) = sub(x),
```

where sub(*x*) and sub(*y*) are *n*-element distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1;

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy*=*m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy*= 1.

Input Parameters

n	(global) INTEGER. The length of distributed vectors, *n*≥0.
x	(local) REAL for pscopy DOUBLE PRECISION for pdcopy COMPLEX for pccopy DOUBLE COMPLEX for pzcopy INTEGER for picopy Array, size (*jx*-1)**m_x* + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).

ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.
descx	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
y	(local) REAL for pscopy DOUBLE PRECISION for pdcopy COMPLEX for pccopy DOUBLE COMPLEX for pzcopy INTEGER for picopy Array, size (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*Y*), respectively.
descy	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y	Overwritten with the distributed vector sub(*x*).

p?dot

Computes the dot product of two distributed real vectors.

Syntax

```
call psdot(n, dot, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pddot(n, dot, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- mkl_pblas.h

Description

The ?dot functions compute the dot product *dot* of two distributed real vectors defined as

```
dot  = sub(x)'*sub(y)
```

where sub(*x*) and sub(*y*) are *n*-element distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1;

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy*=*m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy*= 1.

Input Parameters

n — (global) INTEGER. The length of distributed vectors, *n*≥0.

x — (local) REAL for psdot

DOUBLE PRECISION for pddot

Array, size (*jx*-1)**m_x* + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx* — (global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.

descx — (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx — (global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

y — (local)REAL for psdot

DOUBLE PRECISION for pddot

Array, size (*jy*-1)**m_y* + *iy*+(*n*-1)*abs(*incy*)).

This array contains the entries of the distributed vector sub(*y*).

iy, *jy* — (global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*Y*), respectively.

descy — (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.

incy — (global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

dot — (local) REAL for psdot

DOUBLE PRECISION for pddot

Dot product of sub(*x*) and sub(*y*) only in their scope.

p?dotc

Computes the dot product of two distributed complex vectors, one of them is conjugated.

Syntax

```
call pcdotc(n, dotc, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzdotc(n, dotc, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- mkl_pblas.h

Description

The p?dotc functions compute the dot product *dotc* of two distributed vectors, with one vector conjugated:

```
dotc  = conjg(sub(x)')*sub(y)
```

where sub(*x*) and sub(*y*) are *n*-element distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1;

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy*=*m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy*= 1.

Input Parameters

n
(global) INTEGER. The length of distributed vectors, *n*≥0.

x
(local)COMPLEX for pcdotc

DOUBLE COMPLEX for pzdotc

Array, size (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx*
(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.

descx
(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx
(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

y
(local) COMPLEX for pcdotc

DOUBLE COMPLEX for pzdotc

Array, size (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)).

This array contains the entries of the distributed vector sub(*y*).

iy, *jy*
(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*Y*), respectively.

descy
(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.

incy
(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

dotc
(local) COMPLEX for pcdotc

DOUBLE COMPLEX for pzdotc

Dot product of sub(*x*) and sub(*y*) only in their scope.

p?dotu

Computes the dot product of two distributed complex vectors.

Syntax

```
call pcdotu(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzdotu(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- mkl_pblas.h

Description

The p?dotu functions compute the dot product *dotu* of two distributed vectors defined as

```
dotu  = sub(x)'*sub(y)
```

where sub(*x*) and sub(*y*) are *n*-element distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1;

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy*=*m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy*= 1.

Input Parameters

n
(global) INTEGER. The length of distributed vectors, *n*≥0.

x
(local) COMPLEX for pcdotu
DOUBLE COMPLEX for pzdotu
Array, size (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).
This array contains the entries of the distributed vector sub(*x*).

ix, *jx*
(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.

descx
(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx
(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

y
(local) COMPLEX for pcdotu
DOUBLE COMPLEX for pzdotu
Array, size (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)).
This array contains the entries of the distributed vector sub(*y*).

iy, *jy*
(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*Y*), respectively.

descy
(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.

incy (global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

dotu (local) COMPLEX for pcdotu

DOUBLE COMPLEX for pzdotu

Dot product of sub(*x*) and sub(*y*) only in their scope.

p?nrm2

Computes the Euclidean norm of a distributed vector.

Syntax

```
call psnrm2(n, norm2, x, ix, jx, descx, incx)
call pdnrm2(n, norm2, x, ix, jx, descx, incx)
call pscnrm2(n, norm2, x, ix, jx, descx, incx)
call pdznrm2(n, norm2, x, ix, jx, descx, incx)
```

Include Files

- mkl_pblas.h

Description

The p?nrm2 functions compute the Euclidean norm of a distributed vector sub(*x*),

where sub(*x*) is an *n*-element distributed vector.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1.

Input Parameters

n (global) INTEGER. The length of distributed vector sub(*x*), *n*≥0.

x (local) REAL for psnrm2

DOUBLE PRECISION for pdnrm2

COMPLEX for pscnrm2

DOUBLE COMPLEX for pdznrm2

Array, size (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx* (global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.

descx (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx (global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

norm2 (local) REAL for psnrm2 and pscnrm2.

DOUBLE PRECISION for pdnrm2 and pdznrm2

Contains the Euclidean norm of a distributed vector only in its scope.

p?scal

Computes a product of a distributed vector by a scalar.

Syntax

```
call psscal(n, a, x, ix, jx, descx, incx)
call pdscal(n, a, x, ix, jx, descx, incx)
call pcscal(n, a, x, ix, jx, descx, incx)
call pzscal(n, a, x, ix, jx, descx, incx)
call pcsscal(n, a, x, ix, jx, descx, incx)
call pzdscal(n, a, x, ix, jx, descx, incx)
```

Include Files

- mkl_pblas.h

Description

The p?scal routines multiplies a n-element distributed vector sub(x) by the scalar a:

```
sub(x) = a*sub(x),
```

where sub(x) denotes $X(ix, jx:jx+n-1)$ if $incx=m\_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$.

Input Parameters

n (global) INTEGER. The length of distributed vector sub(x), $n \geq 0$.

a (global) REAL for psscal and pcsscal

DOUBLE PRECISION for pdscal and pzdscal

COMPLEX for pcscal

DOUBLE COMPLEX for pzscal

Specifies the scalar a.

x (local) REAL for psscal

DOUBLE PRECISION for pdscal

COMPLEX for pcscal and pcsscal

DOUBLE COMPLEX for pzscal and pzdscal

Array, size $(jx-1)*m\_x + ix+(n-1)*abs(incx))$.

This array contains the entries of the distributed vector sub(x).

ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.
descx	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

x	Overwritten by the updated distributed vector sub(*x*)

p?swap

Swaps two distributed vectors.

Syntax

```
call psswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pcswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- mkl_pblas.h

Description

Given two distributed vectors sub(*x*) and sub(*y*), the p?swap routines return vectors sub(*y*) and sub(*x*) swapped, each replacing the other.

Here sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1;

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy*=*m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy*= 1.

Input Parameters

n	(global) INTEGER. The length of distributed vectors, *n*≥0.
x	(local) REAL for psswap DOUBLE PRECISION for pdswap COMPLEX for pcswap DOUBLE COMPLEX for pzswap Array, size (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.

descx	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
y	(local) REAL for psswap DOUBLE PRECISION for pdswap COMPLEX for pcswap DOUBLE COMPLEX for pzswap Array, size (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*Y*), respectively.
descy	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

x	Overwritten by distributed vector sub(*y*).
y	Overwritten by distributed vector sub(*x*).

PBLAS Level 2 Routines

This section describes PBLAS Level 2 routines, which perform distributed matrix-vector operations. Table "PBLAS Level 2 Routine Groups and Their Data Types" lists the PBLAS Level 2 routine groups and the data types associated with them.

PBLAS Level 2 Routine Groups and Their Data Types

Routine Groups	Data Types	Description
p?gemv	s, d, c, z	Matrix-vector product using a distributed general matrix
p?agemv	s, d, c, z	Matrix-vector product using absolute values for a distributed general matrix
p?ger	s, d	Rank-1 update of a distributed general matrix
p?gerc	c, z	Rank-1 update (conjugated) of a distributed general matrix
p?geru	c, z	Rank-1 update (unconjugated) of a distributed general matrix
p?hemv	c, z	Matrix-vector product using a distributed Hermitian matrix
p?ahemv	c, z	Matrix-vector product using absolute values for a distributed Hermitian matrix

Routine Groups	Data Types	Description
p?her	c, z	Rank-1 update of a distributed Hermitian matrix
p?her2	c, z	Rank-2 update of a distributed Hermitian matrix
p?symv	s, d	Matrix-vector product using a distributed symmetric matrix
p?asymv	s, d	Matrix-vector product using absolute values for a distributed symmetric matrix
p?syr	s, d	Rank-1 update of a distributed symmetric matrix
p?syr2	s, d	Rank-2 update of a distributed symmetric matrix
p?trmv	s, d, c, z	Distributed matrix-vector product using a triangular matrix
p?atrmv	s, d, c, z	Distributed matrix-vector product using absolute values for a triangular matrix
p?trsv	s, d, c, z	Solves a system of linear equations whose coefficients are in a distributed triangular matrix

p?gemv

Computes a distributed matrix-vector product using a general matrix.

Syntax

```
call psgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pdgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pcgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pzgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

Include Files

- mkl_pblas.h

Description

The p?gemv routines perform a distributed matrix-vector operation defined as

```
sub(y)  := alpha*sub(A)*sub(x) + beta*sub(y),
```

or

```
sub(y)  := alpha*sub(A)'*sub(x) + beta*sub(y),
```

or

```
sub(y)  := alpha*conjg(sub(A)')*sub(x) + beta*sub(y),
```

where

alpha and *beta* are scalars,

sub(*A*) is a *m*-by-*n* submatrix, sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1),

sub(*x*) and sub(*y*) are subvectors.

When *trans* = 'N' or 'n', sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1, sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*m*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*m*-1, *jy*) if *incy* = 1.

When *trans* = 'T' or 't', or 'C', or 'c', sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*m*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*m*-1, *jx*) if *incx* = 1, sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*m*-1, *jy*) if *incy* = 1.

Input Parameters

trans

(global) CHARACTER*1. Specifies the operation:

if *trans*= 'N' or 'n', then sub(*y*) := *alpha**sub(*A*)'*sub(*x*) + *beta**sub(*y*);

if *trans*= 'T' or 't', then sub(*y*) := *alpha**sub(*A*)'*sub(*x*) + *beta**sub(*y*);

if *trans*= 'C' or 'c', then sub(*y*) := *alpha**conjg(sub*A*)')*sub(*x*) + *beta**sub(*y*).

m

(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*A*), *m*≥0.

n

(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*A*), *n*≥0.

alpha

(global)REAL for psgemv

DOUBLE PRECISION for pdgemv

COMPLEX for pcgemv

DOUBLE COMPLEX for pzgemv

Specifies the scalar *alpha*.

a

(local)REAL for psgemv

DOUBLE PRECISION for pdgemv

COMPLEX for pcgemv

DOUBLE COMPLEX for pzgemv

Array, size (*lld_a*, LOCq(*ja*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*A*).

ia, *ja*

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

x

(local)REAL for psgemv

DOUBLE PRECISION for pdgemv

COMPLEX for pcgemv

DOUBLE COMPLEX for pzgemv

Array, size (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)) when *trans* = 'N' or 'n', and (*jx*-1)*m_x + *ix*+(*m*-1)*abs(*incx*)) otherwise.

This array contains the entries of the distributed vector sub(*x*).

ix, *jx* — (global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx — (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx — (global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

beta — (global)REAL for psgemv

DOUBLE PRECISION for pdgemv

COMPLEX for pcgemv

DOUBLE COMPLEX for pzgemv

Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.

y — (local)REAL for psgemv

DOUBLE PRECISION for pdgemv

COMPLEX for pcgemv

DOUBLE COMPLEX for pzgemv

Array, size (*jy*-1)*m_y + *iy*+(*m*-1)*abs(*incy*)) when *trans* = 'N' or 'n', and (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)) otherwise.

This array contains the entries of the distributed vector sub(*y*).

iy, *jy* — (global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.

descy — (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.

incy — (global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y — Overwritten by the updated distributed vector sub(*y*).

p?agemv

Computes a distributed matrix-vector product using absolute values for a general matrix.

Syntax

call psagemv(*trans*, *m*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

call pdagemv(*trans*, *m*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

call pcagemv(*trans*, *m*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

call pzagemv(*trans*, *m*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

Include Files

- mkl_pblas.h

Description

The p?agemv routines perform a distributed matrix-vector operation defined as

```
sub(y)  := abs(alpha)*abs(sub(A)')*abs(sub(x)) + abs(beta*sub(y)),
```

or

```
sub(y)  := abs(alpha)*abs(sub(A)')*abs(sub(x)) + abs(beta*sub(y)),
```

or

```
sub(y)  := abs(alpha)*abs(conjg(sub(A)'))*abs(sub(x)) + abs(beta*sub(y)),
```

where

alpha and *beta* are scalars,

sub(*A*) is a *m*-by-*n* submatrix, sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1),

sub(*x*) and sub(*y*) are subvectors.

When *trans* = 'N' or 'n',

sub(*x*) denotes *X*(*ix*:*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and

X(*ix*:*ix*+*n*-1, *jx*:*jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*:*iy*, *jy*:*jy*+*m*-1) if *incy* = *m_y*, and

Y(*iy*:*iy*+*m*-1, *jy*:*jy*) if *incy* = 1.

When *trans* = 'T' or 't', or 'C', or 'c',

sub(*x*) denotes *X*(*ix*:*ix*, *jx*:*jx*+*m*-1) if *incx* = *m_x*, and

X(*ix*:*ix*+*m*-1, *jx*:*jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*:*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and

Y(*iy*:*iy*+*m*-1, *jy*:*jy*) if *incy* = 1.

Input Parameters

trans (global) CHARACTER*1. Specifies the operation:

if *trans*= 'N' or 'n', then sub(*y*) := |*alpha*|*|sub(*A*)|*|sub(*x*)| + |*beta**sub(*y*)|

if *trans*= 'T' or 't', then sub(*y*) := |*alpha*|*|sub(*A*)'|*|sub(*x*)| + |*beta**sub(*y*)|

if *trans*= 'C' or 'c', then sub(*y*) := |*alpha*|*|sub(*A*)'|*|sub(*x*)| + |*beta**sub(*y*)|.

m (global) INTEGER. Specifies the number of rows of the distributed matrix sub(*A*), *m*≥0.

n (global) INTEGER. Specifies the number of columns of the distributed matrix sub(*A*), *n*≥0.

alpha (global)REAL for psagemv

DOUBLE PRECISION for pdagemv

COMPLEX for pcagemv

DOUBLE COMPLEX for pzagemv

Specifies the scalar *alpha*.

a (local)REAL for psagemv

DOUBLE PRECISION for pdagemv

COMPLEX for pcagemv

DOUBLE COMPLEX for pzagemv

Array, size (*lld_a*, LOCq(*ja*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

x (local)REAL for psagemv

DOUBLE PRECISION for pdagemv

COMPLEX for pcagemv

DOUBLE COMPLEX for pzagemv

Array, size (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)) when *trans* = 'N' or 'n', and (*jx*-1)*m_x + *ix*+(*m*-1)*abs(*incx*)) otherwise.

This array contains the entries of the distributed vector sub(*x*).

ix, *jx* (global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx (global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

beta	(global)REAL for psagemv DOUBLE PRECISION for pdagemv COMPLEX for pcagemv DOUBLE COMPLEX for pzagemv Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.
y	(local)REAL for psagemv DOUBLE PRECISION for pdagemv COMPLEX for pcagemv DOUBLE COMPLEX for pzagemv Array, size (*jy*-1)*m_y + *iy*+(*m*-1)*abs(*incy*)) when *trans* = 'N' or 'n', and (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)) otherwise. This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y	Overwritten by the updated distributed vector sub(*y*).

p?ger

Performs a rank-1 update of a distributed general matrix.

Syntax

```
call psger(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
call pdger(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
```

Include Files

- mkl_pblas.h

Description

The p?ger routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(y)' + sub(A),
```

where:

alpha is a scalar,

sub(*A*) is a *m*-by-*n* distributed general matrix, sub(*A*)=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1),

sub(*x*) is an *m*-element distributed vector, sub(*y*) is an *n*-element distributed vector,

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*m*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*m*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

m
(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*A*), *m*≥0.

n
(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*A*), *n*≥0.

alpha
(global)REAL for psger

DOUBLE REAL for pdger

Specifies the scalar *alpha*.

x
(local)REAL for psger

DOUBLE REAL for pdger

Array, size at least (*jx*-1)*m_x + *ix*+(*m*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx*
(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx
(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx
(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

y
(local)REAL for psger

DOUBLE REAL for pdger

Array, size at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)).

This array contains the entries of the distributed vector sub(*y*).

iy, *jy*
(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.

descy
(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.

incy
(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

a
(local)REAL for psger

DOUBLE REAL for pdger

Array, size (*lld_a*, LOCq(*ja*+*n*-1)).

	Before entry this array contains the local pieces of the distributed matrix sub(*A*).
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

Output Parameters

a	Overwritten by the updated distributed matrix sub(*A*).

p?gerc

Performs a rank-1 update (conjugated) of a distributed general matrix.

Syntax

```
call pcgerc(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
call pzgerc(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
```

Include Files

- mkl_pblas.h

Description

The p?gerc routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*conjg(sub(y)') + sub(A),
```

where:

alpha is a scalar,

sub(*A*) is a *m*-by-*n* distributed general matrix, sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1),

sub(*x*) is an *m*-element distributed vector, sub(*y*) is an*n*-element distributed vector,

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*m*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*m*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

m	(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*A*), *m*≥ 0.
n	(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*A*), *n*≥ 0.
alpha	(global)COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Specifies the scalar *alpha*.

x	(local)COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Array, size at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.
descx	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
y	(local)COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Array, size at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.
a	(local)COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Array, size at least (*lld_a*, LOCq(*ja*+*n*-1)). Before entry this array contains the local pieces of the distributed matrix sub(*A*).
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

Output Parameters

a	Overwritten by the updated distributed matrix sub(*A*).

p?geru

Performs a rank-1 update (unconjugated) of a distributed general matrix.

Syntax

call pcgeru(*m*, *n*, *alpha*, *x*, *ix*, *jx*, *descx*, *incx*, *y*, *iy*, *jy*, *descy*, *incy*, *a*, *ia*, *ja*, *desca*)

call pzgeru(*m*, *n*, *alpha*, *x*, *ix*, *jx*, *descx*, *incx*, *y*, *iy*, *jy*, *descy*, *incy*, *a*, *ia*, *ja*, *desca*)

Include Files

- mkl_pblas.h

Description

The p?geru routines perform a matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(y)' + sub(A),
```

where:

alpha is a scalar,

sub(*A*) is a *m*-by-*n* distributed general matrix, sub(*A*)=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1),

sub(*x*) is an *m*-element distributed vector, sub(*y*) is an *n*-element distributed vector,

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*m*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*m*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

m

(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*A*), *m*≥ 0.

n

(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*A*), *n*≥ 0.

alpha

(global)COMPLEX for pcgeru

DOUBLE COMPLEX for pzgeru

Specifies the scalar *alpha*.

x

(local)COMPLEX for pcgeru

DOUBLE COMPLEX for pzgeru

Array, size at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx*

(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx

(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

y

(local)COMPLEX for pcgeru

DOUBLE COMPLEX for pzgeru

	Array, size at least `(jy-1)*m_y + iy+(n-1)*abs(incy))`. This array contains the entries of the distributed vector `sub(y)`.
iy, *jy*	(global) `INTEGER`. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix `sub(y)`, respectively.
descy	(global and local) `INTEGER` array of dimension 9. The array descriptor of the distributed matrix *Y*.
incy	(global) `INTEGER`. Specifies the increment for the elements of `sub(y)`. Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.
a	(local)`COMPLEX` for `pcgeru` `DOUBLE COMPLEX` for `pzgeru` Array, size at least `(lld_a, LOCq(ja+n-1))`. Before entry this array contains the local pieces of the distributed matrix `sub(A)`.
ia, *ja*	(global) `INTEGER`. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix `sub(A)`, respectively.
desca	(global and local) `INTEGER` array of dimension 9. The array descriptor of the distributed matrix *A*.

Output Parameters

a	Overwritten by the updated distributed matrix `sub(A)`.

p?hemv

Computes a distributed matrix-vector product using a Hermitian matrix.

Syntax

`call pchemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)`

`call pzhemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)`

Include Files

- `mkl_pblas.h`

Description

The `p?hemv` routines perform a distributed matrix-vector operation defined as

```
sub(y) := alpha*sub(A)*sub(x) + beta*sub(y),
```

where:

alpha and *beta* are scalars,

`sub(A)` is a *n*-by-*n* Hermitian distributed matrix, `sub(A)=A(ia:ia+n-1, ja:ja+n-1)` ,

`sub(x)` and `sub(y)` are distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

uplo

(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix sub(*A*) is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used.

If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.

n

(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), $n \geq 0$.

alpha

(global)COMPLEX for pchemv

DOUBLE COMPLEX for pzhemv

Specifies the scalar *alpha*.

a

(local)COMPLEX for pchemv

DOUBLE COMPLEX for pzhemv

Array, size (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*).

Before entry when *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and when *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja*

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

x

(local)COMPLEX for pchemv

DOUBLE COMPLEX for pzhemv

Array, size at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx*

(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
beta	(global)COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.
y	(local)COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, size at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y	Overwritten by the updated distributed vector sub(*y*).

p?ahemv

Computes a distributed matrix-vector product using absolute values for a Hermitian matrix.

Syntax

```
call pcahemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

```
call pzahemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

Include Files

- mkl_pblas.h

Description

The p?ahemv routines perform a distributed matrix-vector operation defined as

```
sub(y) := abs(alpha)*abs(sub(A))*abs(sub(x)) + abs(beta*sub(y)),
```

where:

alpha and *beta* are scalars,

sub(*A*) is a *n*-by-*n* Hermitian distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) ,

sub(*x*) and sub(*y*) are distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

uplo

(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix sub(*A*) is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used.

If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.

n

(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n*≥ 0.

alpha

(global)COMPLEX for pcahemv

DOUBLE COMPLEX for pzahemv

Specifies the scalar *alpha*.

a

(local)COMPLEX for pcahemv

DOUBLE COMPLEX for pzahemv

Array, size (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*).

Before entry when *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and when *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja*

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

x

(local)COMPLEX for pcahemv

DOUBLE COMPLEX for pzahemv

Array, size at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx*

(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx

(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

beta	(global)COMPLEX for pcahemv DOUBLE COMPLEX for pzahemv Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.
y	(local)COMPLEX for pcahemv DOUBLE COMPLEX for pzahemv Array, size at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y	Overwritten by the updated distributed vector sub(*y*).

p?her

Performs a rank-1 update of a distributed Hermitian matrix.

Syntax

```
call pcher(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
call pzher(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
```

Include Files

- mkl_pblas.h

Description

The p?her routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*conjg(sub(x)') + sub(A),
```

where:

alpha is a real scalar,

sub(*A*) is a *n*-by-*n* distributed Hermitian matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1),

sub(*x*) is distributed vector.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1.

Input Parameters

uplo

(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix sub(*A*) is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used.

If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.

n

(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), $n \geq 0$.

alpha

(global)REAL for pcher

DOUBLE REAL for pzher

Specifies the scalar *alpha*.

x

(local)COMPLEX for pcher

DOUBLE COMPLEX for pzher

Array, size at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx*

(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx

(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

a

(local)COMPLEX for pcher

DOUBLE COMPLEX for pzher

Array, size (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*).

Before entry with *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and with *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja*

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

Output Parameters

a — With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated distributed matrix sub(*A*).

With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated distributed matrix sub(*A*).

p?her2

Performs a rank-2 update of a distributed Hermitian matrix.

Syntax

call pcher2(*uplo*, *n*, *alpha*, *x*, *ix*, *jx*, *descx*, *incx*, *y*, *iy*, *jy*, *descy*, *incy*, *a*, *ia*, *ja*, *desca*)

call pzher2(*uplo*, *n*, *alpha*, *x*, *ix*, *jx*, *descx*, *incx*, *y*, *iy*, *jy*, *descy*, *incy*, *a*, *ia*, *ja*, *desca*)

Include Files

- mkl_pblas.h

Description

The p?her2 routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*conj(sub(y)')+ conj(alpha)*sub(y)*conj(sub(x)') + sub(A),
```

where:

alpha is a scalar,

sub(*A*) is a *n*-by-*n* distributed Hermitian matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1),

sub(*x*) and sub(*y*) are distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

uplo — (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the distributed Hermitian matrix sub(*A*) is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used.

If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.

n — (global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n*≥ 0.

alpha — (global)COMPLEX for pcher2

DOUBLE COMPLEX for pzher2

Specifies the scalar *alpha*.

x (local)COMPLEX for pcher2

DOUBLE COMPLEX for pzher2

Array, size at least (*jx*-1)*m_*x* + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx* (global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx (global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

y (local)COMPLEX for pcher2

DOUBLE COMPLEX for pzher2

Array, size at least (*jy*-1)*m_*y* + *iy*+(*n*-1)*abs(*incy*)).

This array contains the entries of the distributed vector sub(*y*).

iy, *jy* (global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.

descy (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.

incy (global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

a (local)COMPLEX for pcher2

DOUBLE COMPLEX for pzher2

Array, size (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*).

Before entry with *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and with *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

Output Parameters

a — With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated distributed matrix sub(*A*).

With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated distributed matrix sub(*A*).

p?symv

Computes a distributed matrix-vector product using a symmetric matrix.

Syntax

```
call pssymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pdsymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

Include Files

- mkl_pblas.h

Description

The p?symv routines perform a distributed matrix-vector operation defined as

```
sub(y)  := alpha*sub(A)*sub(x) + beta*sub(y),
```

where:

alpha and *beta* are scalars,

sub(*A*) is a *n*-by-*n* symmetric distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) ,

sub(*x*) and sub(*y*) are distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

uplo — (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix sub(*A*) is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used.

If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.

n — (global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n*≥ 0.

alpha — (global)REAL for pssymv

DOUBLE REAL for pdsymv

Specifies the scalar *alpha*.

a

(local)REAL for pssymv

DOUBLE REAL for pdsymv

Array, size (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*).

Before entry when *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and when *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja*

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

x

(local)REAL for pssymv

DOUBLE REAL for pdsymv

Array, size at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx*

(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx

(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

beta

(global)REAL for pssymv

DOUBLE REAL for pdsymv

Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.

y

(local)REAL for pssymv

DOUBLE REAL for pdsymv

Array, size at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)).

This array contains the entries of the distributed vector sub(*y*).

iy, *jy*

(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.

descy

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.

incy (global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y Overwritten by the updated distributed vector sub(*y*).

p?asymv

Computes a distributed matrix-vector product using absolute values for a symmetric matrix.

Syntax

call psasymv(*uplo*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

call pdasymv(*uplo*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

Include Files

- mkl_pblas.h

Description

The p?symv routines perform a distributed matrix-vector operation defined as

```
sub(y)  := abs(alpha)*abs(sub(A))*abs(sub(x)) + abs(beta*sub(y)),
```

where:

alpha and *beta* are scalars,

sub(*A*) is a *n*-by-*n* symmetric distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) ,

sub(*x*) and sub(*y*) are distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

uplo (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix sub(*A*) is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used.

If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.

n (global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n*≥ 0.

alpha (global)REAL for psasymv

DOUBLE REAL for pdasymv

Specifies the scalar *alpha*.

a (local)REAL for psasymv

DOUBLE REAL for pdasymv

Array, size (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*).

Before entry when *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and when *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja*

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

x

(local)REAL for psasymv

DOUBLE PRECISION for pdasymv

Array, size at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx*

(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx

(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

beta

(global)REAL for psasymv

DOUBLE PRECISION for pdasymv

Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.

y

(local)REAL for psasymv

DOUBLE PRECISION for pdasymv

Array, size at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)).

This array contains the entries of the distributed vector sub(*y*).

iy, *jy*

(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.

descy

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.

incy (global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y Overwritten by the updated distributed vector sub(*y*).

p?syr

Performs a rank-1 update of a distributed symmetric matrix.

Syntax

```
call pssyr(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
call pdsyr(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
```

Include Files

- mkl_pblas.h

Description

The p?syr routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(x)' + sub(A),
```

where:

alpha is a scalar,

sub(*A*) is a *n*-by-*n* distributed symmetric matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) ,

sub(*x*) is distributed vector.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

Input Parameters

uplo (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix sub(*A*) is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used.

If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.

n (global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n*≥ 0.

alpha (global)REAL for pssyr

DOUBLE REAL for pdsyr

Specifies the scalar *alpha*.

x (local)REAL for pssyr

DOUBLE REAL for pdsyr

Array, size at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx*

(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx

(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

a

(local)REAL for pssyr

DOUBLE REAL for pdsyr

Array, size (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*).

Before entry with *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and with *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja*

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

Output Parameters

a

With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated distributed matrix sub(*A*).

With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated distributed matrix sub(*A*).

p?syr2

Performs a rank-2 update of a distributed symmetric matrix.

Syntax

call pssyr2(*uplo*, *n*, *alpha*, *x*, *ix*, *jx*, *descx*, *incx*, *y*, *iy*, *jy*, *descy*, *incy*, *a*, *ia*, *ja*, *desca*)

call pdsyr2(*uplo*, *n*, *alpha*, *x*, *ix*, *jx*, *descx*, *incx*, *y*, *iy*, *jy*, *descy*, *incy*, *a*, *ia*, *ja*, *desca*)

Include Files

- mkl_pblas.h

Description

The p?syr2 routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(y)'+ alpha*sub(y)*sub(x)' + sub(A),
```

where:

alpha is a scalar,

sub(*A*) is a *n*-by-*n* distributed symmetric matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) ,

sub(*x*) and sub(*y*) are distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

uplo

(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the distributed symmetric matrix sub(*A*) is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used.

If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.

n

(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n*≥ 0.

alpha

(global)REAL for pssyr2

DOUBLE REAL for pdsyr2

Specifies the scalar *alpha*.

x

(local)REAL for pssyr2

DOUBLE REAL for pdsyr2

Array, size at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx*

(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx

(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

y

(local)REAL for pssyr2

DOUBLE REAL for pdsyr2

Array, size at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)).

This array contains the entries of the distributed vector sub(*y*).

iy, *jy* (global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.

descy (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.

incy (global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

a (local)REAL for pssyr2

DOUBLE REAL for pdsyr2

Array, size (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*).

Before entry with *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the distributed symmetric matrix and the strictly lower triangular part of sub(*A*) is not referenced, and with *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the distributed symmetric matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

Output Parameters

a With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated distributed matrix sub(*A*).

With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated distributed matrix sub(*A*).

p?trmv

Computes a distributed matrix-vector product using a triangular matrix.

Syntax

```
call pstrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pdtrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pctrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pztrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
```

Include Files

- mkl_pblas.h

Description

The p?trmv routines perform one of the following distributed matrix-vector operations defined as

sub(*x*) := sub(*A*)*sub(*x*), or sub(*x*) :=sub(*A*)'*sub(*x*), or sub(*x*) := conjg(sub(*A*)')*sub(*x*),

where:

sub(*A*) is a *n*-by-*n* unit, or non-unit, upper or lower triangular distributed matrix, sub(*A*) = *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1),

sub(*x*) is an *n*-element distributed vector.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

Input Parameters

uplo

(global) CHARACTER*1. Specifies whether the distributed matrix sub(*A*) is upper or lower triangular:

if *uplo* = 'U' or 'u', then the matrix is upper triangular;

if *uplo* = 'L' or 'l', then the matrix is low triangular.

trans

(global) CHARACTER*1. Specifies the form of op(sub(*A*)) used in the matrix equation:

if *transa* = 'N' or 'n', then sub(*x*) := sub(*A*)*sub(*x*);

if *transa* = 'T' or 't', then sub(*x*) :=sub(*A*)'*sub(*x*);

if *transa* = 'C' or 'c', then sub(*x*) := conjg(sub(*A*)')*sub(*x*).

diag

(global) CHARACTER*1. Specifies whether the matrix sub(*A*) is unit triangular:

if *diag* = 'U' or 'u' then the matrix is unit triangular;

if *diag* = 'N' or 'n', then the matrix is not unit triangular.

n

(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n*≥0.

a

(local)REAL for pstrmv

DOUBLE PRECISION for pdtrmv

COMPLEX for pctrmv

DOUBLE COMPLEX for pztrmv

Array, size at least (*lld_a*, LOCq(1, *ja*+*n*-1)).

Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix sub(*A*) is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix sub(*A*) is not referenced .

When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix sub(*A*) are not referenced either, but are assumed to be unity.

ia, *ja*
(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca
(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

x
(local)REAL for pstrmv

DOUBLE PRECISION for pdtrmv

COMPLEX for pctrmv

DOUBLE COMPLEX for pztrmv

Array, size at least (*jx*-1)**m_x* + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx*
(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx
(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx
(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

x
Overwritten by the transformed distributed vector sub(*x*).

p?atrmv

Computes a distributed matrix-vector product using absolute values for a triangular matrix.

Syntax

call psatrmv(*uplo*, *trans*, *diag*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

call pdatrmv(*uplo*, *trans*, *diag*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

call pcatrmv(*uplo*, *trans*, *diag*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

call pzatrmv(*uplo*, *trans*, *diag*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

Include Files

- mkl_pblas.h

Description

The p?atrmv routines perform one of the following distributed matrix-vector operations defined as

sub(*y*) := abs(*alpha*)*abs(sub(*A*))*abs(sub(*x*))+ abs(*beta**sub(*y*)), or

sub(*y*) := abs(*alpha*)*abs(sub(*A*)')*abs(sub(*x*))+ abs(*beta**sub(*y*)), or

sub(*y*) := abs(*alpha*)*abs(conjg(sub(*A*)'))*abs(sub(*x*))+ abs(*beta**sub(*y*)),

where:

alpha and *beta* are scalars,

sub(*A*) is a *n*-by-*n* unit, or non-unit, upper or lower triangular distributed matrix, sub(*A*) = *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1),

sub(*x*) is an *n*-element distributed vector.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1.

Input Parameters

uplo

(global) CHARACTER*1. Specifies whether the distributed matrix sub(*A*) is upper or lower triangular:

if *uplo* = 'U' or 'u', then the matrix is upper triangular;

if *uplo* = 'L' or 'l', then the matrix is low triangular.

trans

(global) CHARACTER*1. Specifies the form of op(sub(*A*)) used in the matrix equation:

if *trans* = 'N' or 'n', then sub(*y*) := |*alpha*|*|sub(*A*)|*|sub(*x*)|+|*beta**sub(*y*)|;

if *trans* = 'T' or 't', then sub(*y*) := |*alpha*|*|sub(*A*)'|*|sub(*x*)|+|*beta**sub(*y*)|;

if *trans* = 'C' or 'c', then sub(*y*) := |*alpha*|*|conjg(sub(*A*)')|*|sub(*x*)|+|*beta**sub(*y*)|.

diag

(global) CHARACTER*1. Specifies whether the matrix sub(*A*) is unit triangular:

if *diag* = 'U' or 'u' then the matrix is unit triangular;

if *diag* = 'N' or 'n', then the matrix is not unit triangular.

n

(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n*≥0.

alpha

(global)REAL for psatrmv

DOUBLE PRECISION for pdatrmv

COMPLEX for pcatrmv

DOUBLE COMPLEX for pzatrmv

Specifies the scalar *alpha*.

a

(local)REAL for psatrmv

DOUBLE PRECISION for pdatrmv

COMPLEX for pcatrmv

DOUBLE COMPLEX for pzatrmv

Array, size at least (*lld_a*, LOCq(1, *ja*+*n*-1)).

Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix sub(*A*) is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix sub(*A*) is not referenced.

When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix sub(*A*) are not referenced either, but are assumed to be unity.

ia, *ja*

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

x

(local)REAL for psatrmv

DOUBLE PRECISION for pdatrmv

COMPLEX for pcatrmv

DOUBLE COMPLEX for pzatrmv

Array, size at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).

This array contains the entries of the distributed vector sub(*x*).

ix, *jx*

(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.

incx

(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

beta

(global)REAL for psatrmv

DOUBLE PRECISION for pdatrmv

COMPLEX for pcatrmv

DOUBLE COMPLEX for pzatrmv

Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.

y

(local)REAL for psatrmv

DOUBLE PRECISION for pdatrmv

COMPLEX for pcatrmv

DOUBLE COMPLEX for pzatrmv

Array, size (*jy*-1)*m_y + *iy*+(*m*-1)*abs(*incy*)) when *trans* = 'N' or 'n', and (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)) otherwise.

This array contains the entries of the distributed vector sub(*y*).

iy, *jy* — (global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.

descy — (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *Y*.

incy — (global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y — Overwritten by the transformed distributed vector sub(*y*).

p?trsv

Solves a system of linear equations whose coefficients are in a distributed triangular matrix.

Syntax

```
call pstrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pdtrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pctrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pztrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
```

Include Files

- mkl_pblas.h

Description

The p?trsv routines solve one of the systems of equations:

sub(*A*)*sub(*x*) = *b*, or sub(*A*)'*sub(*x*) = *b*, or conjg(sub(*A*)')*sub(*x*) = *b*,

where:

sub(*A*) is a *n*-by-*n* unit, or non-unit, upper or lower triangular distributed matrix, sub(*A*) = *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1),

b and sub(*x*) are *n*-element distributed vectors,

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,.

The routine does not test for singularity or near-singularity. Such tests must be performed before calling this routine.

Input Parameters

uplo — (global) CHARACTER*1. Specifies whether the distributed matrix sub(*A*) is upper or lower triangular:

if *uplo* = 'U' or 'u', then the matrix is upper triangular;

if *uplo* = 'L' or 'l', then the matrix is low triangular.

trans (global) CHARACTER*1. Specifies the form of the system of equations:

if *transa* = 'N' or 'n', then sub(*A*)*sub(*x*) = *b*;

if *transa* = 'T' or 't', then sub(*A*)'*sub(*x*) = *b*;

if *transa* = 'C' or 'c', then conjg(sub(*A*)')*sub(*x*) = *b*.

diag (global) CHARACTER*1. Specifies whether the matrix sub(*A*) is unit triangular:

if *diag* = 'U' or 'u' then the matrix is unit triangular;

if *diag* = 'N' or 'n', then the matrix is not unit triangular.

n (global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n*≥ 0.

a (local)REAL for pstrsv

DOUBLE PRECISION for pdtrsv

COMPLEX for pctrsv

DOUBLE COMPLEX for pztrsv

Array, size at least (*lld_a*, LOCq(1, *ja*+*n*-1)).

Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix sub(*A*) is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix sub(*A*) is not referenced .

When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix sub(*A*) are not referenced either, but are assumed to be unity.

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

x (local)REAL for pstrsv

DOUBLE PRECISION for pdtrsv

COMPLEX for pctrsv

DOUBLE COMPLEX for pztrsv

Array, size at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).

	This array contains the entries of the distributed vector sub(*x*). Before entry, sub(*x*) must contain the *n*-element right-hand side distributed vector *b*.
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.
descx	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

x	Overwritten with the solution vector.

PBLAS Level 3 Routines

The PBLAS Level 3 routines perform distributed matrix-matrix operations. Table "PBLAS Level 3 Routine Groups and Their Data Types" lists the PBLAS Level 3 routine groups and the data types associated with them.

PBLAS Level 3 Routine Groups and Their Data Types

Routine Group	Data Types	Description
p?geadd	s, d, c, z	Distributed matrix-matrix sum of general matrices
p?tradd	s, d, c, z	Distributed matrix-matrix sum of triangular matrices
p?gemm	s, d, c, z	Distributed matrix-matrix product of general matrices
p?hemm	c, z	Distributed matrix-matrix product, one matrix is Hermitian
p?herk	c, z	Rank-k update of a distributed Hermitian matrix
p?her2k	c, z	Rank-2k update of a distributed Hermitian matrix
p?symm	s, d, c, z	Matrix-matrix product of distributed symmetric matrices
p?syrk	s, d, c, z	Rank-k update of a distributed symmetric matrix
p?syr2k	s, d, c, z	Rank-2k update of a distributed symmetric matrix
p?tran	s, d	Transposition of a real distributed matrix
p?tranc	c, z	Transposition of a complex distributed matrix (conjugated)
p?tranu	c, z	Transposition of a complex distributed matrix
p?trmm	s, d, c, z	Distributed matrix-matrix product, one matrix is triangular
p?trsm	s, d, c, z	Solution of a distributed matrix equation, one matrix is triangular

p?geadd

Performs sum operation for two distributed general matrices.

Syntax

```
call psgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pdgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pcgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pzgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- mkl_pblas.h

Description

The p?geadd routines perform sum operation for two distributed general matrices. The operation is defined as

```
sub(C):=beta*sub(C) + alpha*op(sub(A)),
```

where:

op(*x*) is one of op(*x*) = *x*, or op(*x*) = *x*',

alpha and *beta* are scalars,

sub(*C*) is an *m*-by-*n* distributed matrix, sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*m*-1).

Input Parameters

trans

(global) CHARACTER*1. Specifies the operation:

if *trans* = 'N' or 'n', then op(sub(*A*)) := sub(*A*);

if *trans* = 'T' or 't', then op(sub(*A*)) := sub(*A*)';

if *trans* = 'C' or 'c', then op(sub(*A*)) := sub(*A*)'.

m

(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*C*) and the number of columns of the submatrix sub(*A*), $m \geq 0$.

n

(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*C*) and the number of rows of the submatrix sub(*A*), $n \geq 0$.

alpha

(global)REAL for psgeadd

DOUBLE PRECISION for pdgeadd

COMPLEX for pcgeadd

DOUBLE COMPLEX for pzgeadd

Specifies the scalar *alpha*.

a

(local)REAL for psgeadd

DOUBLE PRECISION for pdgeadd

COMPLEX for pcgeadd

DOUBLE COMPLEX for pzgeadd

Array, size (*lld_a*, LOCq(*ja*+*m*-1)). This array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja* — (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca — (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

beta — (global)REAL for psgeadd

DOUBLE PRECISION for pdgeadd

COMPLEX for pcgeadd

DOUBLE COMPLEX for pzgeadd

Specifies the scalar *beta*.

When *beta* is equal to zero, then sub(*C*) need not be set on input.

c — (local)REAL for psgeadd

DOUBLE PRECISION for pdgeadd

COMPLEX for pcgeadd

DOUBLE COMPLEX for pzgeadd

Array, size (*lld_c*, LOCq(*jc*+*n*-1)).

This array contains the local pieces of the distributed matrix sub(*C*).

ic, *jc* — (global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.

descc — (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c — Overwritten by the updated submatrix.

p?tradd

Performs sum operation for two distributed triangular matrices.

Syntax

```
call pstradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pdtradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pctradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pztradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- mkl_pblas.h

Description

The p?tradd routines perform sum operation for two distributed triangular matrices. The operation is defined as

```
sub(C):=beta*sub(C) + alpha*op(sub(A)),
```

where:

op(*x*) is one of op(*x*) = *x*, or op(*x*) = *x*', or op(*x*) = conjg(*x*').

alpha and *beta* are scalars,

sub(*C*) is an *m*-by-*n* distributed matrix, sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*m*-1).

Input Parameters

uplo

(global) CHARACTER*1. Specifies whether the distributed matrix sub(*C*) is upper or lower triangular:

if *uplo* = 'U' or 'u', then the matrix is upper triangular;

if *uplo* = 'L' or 'l', then the matrix is low triangular.

trans

(global) CHARACTER*1. Specifies the operation:

if *trans* = 'N' or 'n', then op(sub(*A*)) := sub(*A*);

if *trans* = 'T' or 't', then op(sub(*A*)) := sub(*A*)';

if *trans* = 'C' or 'c', then op(sub(*A*)) := conjg(sub(*A*)').

m

(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*C*) and the number of columns of the submatrix sub(*A*), $m \geq 0$.

n

(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*C*) and the number of rows of the submatrix sub(*A*), $n \geq 0$.

alpha

(global)REAL for pstradd

DOUBLE PRECISION for pdtradd

COMPLEX for pctradd

DOUBLE COMPLEX for pztradd

Specifies the scalar *alpha*.

a

(local)REAL for pstradd

DOUBLE PRECISION for pdtradd

COMPLEX for pctradd

DOUBLE COMPLEX for pztradd

Array, size (*lld_a*, LOCq(*ja*+*m*-1)). This array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.
beta	(global)REAL for pstradd DOUBLE PRECISION for pdtradd COMPLEX for pctradd DOUBLE COMPLEX for pztradd Specifies the scalar *beta*. When *beta* is equal to zero, then sub(*C*) need not be set on input.
c	(local)REAL for pstradd DOUBLE PRECISION for pdtradd COMPLEX for pctradd DOUBLE COMPLEX for pztradd Array, size (*lld_c*, LOCq(*jc*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*C*).
ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.
descc	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c	Overwritten by the updated submatrix.

p?gemm

Computes a scalar-matrix-matrix product and adds the result to a scalar-matrix product for distributed matrices.

Syntax

call psgemm(*transa*, *transb*, *m*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pdgemm(*transa*, *transb*, *m*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pcgemm(*transa*, *transb*, *m*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pzgemm(*transa*, *transb*, *m*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

Include Files

- mkl_pblas.h

Description

The p?gemm routines perform a matrix-matrix operation with general distributed matrices. The operation is defined as

```
sub(C) := alpha*op(sub(A))*op(sub(B)) + beta*sub(C),
```

where:

op(*x*) is one of op(*x*) = *x*, or op(*x*) = *x*',

alpha and *beta* are scalars,

sub(*A*)=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*k*-1), sub(*B*)=*B*(*ib*:*ib*+*k*-1, *jb*:*jb*+*n*-1), and sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1), are distributed matrices.

Input Parameters

transa

(global) CHARACTER*1. Specifies the form of op(sub(*A*)) used in the matrix multiplication:

if *transa* = 'N' or 'n', then op(sub(*A*)) = sub(*A*);

if *transa* = 'T' or 't', then op(sub(*A*)) = sub(*A*)';

if *transa* = 'C' or 'c', then op(sub(*A*)) = sub(*A*)'.

transb

(global) CHARACTER*1. Specifies the form of op(sub(*B*)) used in the matrix multiplication:

if *transb* = 'N' or 'n', then op(sub(*B*)) = sub(*B*);

if *transb* = 'T' or 't', then op(sub(*B*)) = sub(*B*)';

if *transb* = 'C' or 'c', then op(sub(*B*)) = sub(*B*)'.

m

(global) INTEGER. Specifies the number of rows of the distributed matrices op(sub(*A*)) and sub(*C*), $m \geq 0$.

n

(global) INTEGER. Specifies the number of columns of the distributed matrices op(sub(*B*)) and sub(*C*), $n \geq 0$.

The value of *n* must be at least zero.

k

(global) INTEGER. Specifies the number of columns of the distributed matrix op(sub(*A*)) and the number of rows of the distributed matrix op(sub(*B*)).

The value of *k* must be greater than or equal to 0.

alpha

(global)REAL for psgemm

DOUBLE PRECISION for pdgemm

COMPLEX for pcgemm

DOUBLE COMPLEX for pzgemm

Specifies the scalar *alpha*.

When *alpha* is equal to zero, then the local entries of the arrays *a* and *b* corresponding to the entries of the submatrices sub(*A*) and sub(*B*) respectively need not be set on input.

a (local) REAL for psgemm

DOUBLE PRECISION for pdgemm

COMPLEX for pcgemm

DOUBLE COMPLEX for pzgemm

Array, size *lld_a* by *kla*, where *kla* is LOCc(*ja*+*k*-1) when *transa* = 'N' or 'n', and is LOCq(*ja*+*m*-1) otherwise. Before entry this array must contain the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively

desca (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

b (local)REAL for psgemm

DOUBLE PRECISION for pdgemm

COMPLEX for pcgemm

DOUBLE COMPLEX for pzgemm

Array, size *lld_b* by *klb*, where *klb* is LOCc(*jb*+*n*-1) when *transb* = 'N' or 'n', and is LOCq(*jb*+*k*-1) otherwise. Before entry this array must contain the local pieces of the distributed matrix sub(*B*).

ib, *jb* (global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively

descb (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *B*.

beta (global)REAL for psgemm

DOUBLE PRECISION for pdgemm

COMPLEX for pcgemm

DOUBLE COMPLEX for pzgemm

Specifies the scalar *beta*.

When *beta* is equal to zero, then sub(*C*) need not be set on input.

c (local)REAL for psgemm

DOUBLE PRECISION for pdgemm

COMPLEX for pcgemm

DOUBLE COMPLEX for pzgemm

Array, size (*lld_a*, LOCq(*jc*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*C*).

ic, *jc* (global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively

descc (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c Overwritten by the *m*-by-*n* distributed matrix *alpha**op(sub(*A*))*op(sub(*B*)) + *beta**sub(*C*).

p?hemm

Performs a scalar-matrix-matrix product (one matrix operand is Hermitian) and adds the result to a scalar-matrix product.

Syntax

call pchemm(*side*, *uplo*, *m*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pzhemm(*side*, *uplo*, *m*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

Include Files

- mkl_pblas.h

Description

The p?hemm routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

sub(*C*):=*alpha**sub(*A*)*sub(*B*)+ *beta**sub(*C*),

or

sub(*C*):=*alpha**sub(*B*)*sub(*A*)+ *beta**sub(*C*),

where:

alpha and *beta* are scalars,

sub(*A*) is a Hermitian distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*m*-1), if *side* = 'L', and sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1), if *side* = 'R'.

sub(*B*) and sub(*C*) are *m*-by-*n* distributed matrices.

sub(*B*)=*B*(*ib*:*ib*+*m*-1, *jb*:*jb*+*n*-1), sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1).

Input Parameters

side (global) CHARACTER*1. Specifies whether the Hermitian distributed matrix sub(*A*) appears on the left or right in the operation:

if *side* = 'L' or 'l', then sub(*C*) := *alpha**sub(*A*) *sub(*B*) + *beta**sub(*C*);

if *side* = 'R' or 'r', then sub(*C*) := *alpha**sub(*B*) *sub(*A*) + *beta**sub(*C*).

uplo (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix sub(*A*) is used:

if *uplo* = 'U' or 'u', then the upper triangular part is used;

if *uplo* = 'L' or 'l', then the lower triangular part is used.

m (global) INTEGER. Specifies the number of rows of the distribute submatrix sub(*C*), $m \geq 0$.

n (global) INTEGER. Specifies the number of columns of the distribute submatrix sub(*C*), $n \geq 0$.

alpha (global)COMPLEX for pchemm

DOUBLE COMPLEX for pzhemm

Specifies the scalar *alpha*.

a (local)COMPLEX for pchemm

DOUBLE COMPLEX for pzhemm

Array, size (*lld_a*, LOCq(*ja*+*na*-1)).

Before entry this array must contain the local pieces of the symmetric distributed matrix sub(*A*), such that when *uplo* = 'U' or 'u', the *na*-by-*na* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and when *uplo* = 'L' or 'l', the *na*-by-*na* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively

desca (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

b (local)COMPLEX for pchemm

DOUBLE COMPLEX for pzhemm

Array, size (*lld_b*, LOCq(*jb*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*B*).

ib, *jb* (global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.

descb (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *B*.

beta (global)COMPLEX for pchemm

DOUBLE COMPLEX for pzhemm

Specifies the scalar *beta*.

When *beta* is set to zero, then sub(*C*) need not be set on input.

c	(local)COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Array, size (*lld_c*, LOCq(*jc*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*C*).
ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively
descc	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c	Overwritten by the *m*-by-*n* updated distributed matrix.

p?herk

Performs a rank-k update of a distributed Hermitian matrix.

Syntax

```
call pcherk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pzherk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- mkl_pblas.h

Description

The p?herk routines perform a distributed matrix-matrix operation defined as

```
sub(C):=alpha*sub(A)*conjg(sub(A)')+ beta*sub(C),
```

or

```
sub(C):=alpha*conjg(sub(A)')*sub(A)+ beta*sub(C),
```

where:

alpha and *beta* are scalars,

sub(*C*) is an *n*-by-*n* Hermitian distributed matrix, sub(*C*)=C(*ic*:*ic*+*n*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*k*-1), if *trans* = 'N' or 'n', and sub(*A*)=*A*(*ia*:*ia*+*k*-1, *ja*:*ja*+*n*-1) otherwise.

Input Parameters

uplo	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix sub(*C*) is used: If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*C*) is used. If *uplo* = 'L' or 'l', then the low triangular part of the sub(*C*) is used.
trans	(global) CHARACTER*1. Specifies the operation:

if *trans* = 'N' or 'n', then sub(*C*) := *alpha**sub(*A*)*conjg(sub(*A*)') + *beta**sub(*C*);

if *trans* = 'C' or 'c', then sub(*C*) := *alpha**conjg(sub(*A*)')*sub(*A*) + *beta**sub(*C*).

n (global) INTEGER. Specifies the order of the distributed matrix sub(*C*), *n*≥ 0.

k (global) INTEGER. On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the distributed matrix sub(*A*) , and on entry with *trans* = 'T' or 't' or 'C' or 'c', *k* specifies the number of rows of the distributed matrix sub(*A*), *k*≥ 0.

alpha (global)REAL for pcherk

DOUBLE PRECISION for pzherk

Specifies the scalar *alpha*.

a (local)COMPLEX for pcherk

DOUBLE COMPLEX for pzherk

Array, size (*lld_a*, *kla*), where *kla* is LOCq(*ja*+*k*-1) when *trans* = 'N' or 'n', and is LOCq(*ja*+*n*-1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

beta (global)REAL for pcherk

DOUBLE PRECISION for pzherk

Specifies the scalar *beta*.

c (local)COMPLEX for pcherk

DOUBLE COMPLEX for pzherk

Array, size (*lld_c*, LOCq(*jc*+*n*-1)).

Before entry with *uplo* = 'U' or 'u', this array contains *n*-by-*n* upper triangular part of the symmetric distributed matrix sub(*C*) and its strictly lower triangular part is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains *n*-by-*n* lower triangular part of the symmetric distributed matrix sub(*C*) and its strictly upper triangular part is not referenced.

ic, *jc* (global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.

descc (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c — With *uplo* = 'U' or 'u', the upper triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.

With *uplo* = 'L' or 'l', the lower triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.

p?her2k

Performs a rank-2k update of a Hermitian distributed matrix.

Syntax

call pcher2k(*uplo*, *trans*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pzher2k(*uplo*, *trans*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

Include Files

- mkl_pblas.h

Description

The p?her2k routines perform a distributed matrix-matrix operation defined as

sub(*C*):=*alpha**sub(*A*)*conjg(sub(*B*)')+ conjg(*alpha*)*sub(*B*)*conjg(sub(*A*)')+*beta**sub(*C*),

or

sub(*C*):=*alpha**conjg(sub(*A*)')*sub(*A*)+ conjg(*alpha*)*conjg(sub(*B*)')*sub(*A*) + *beta**sub(*C*),

where:

alpha and *beta* are scalars,

sub(*C*) is an *n*-by-*n* Hermitian distributed matrix, sub(*C*) = C(*ic*:*ic*+*n*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*k*-1), if *trans* = 'N' or 'n', and sub(*A*) = *A*(*ia*:*ia*+*k*-1, *ja*:*ja*+*n*-1) otherwise.

sub(*B*) is a distributed matrix, sub(*B*) = *B*(*ib*:*ib*+*n*-1, *jb*:*jb*+*k*-1), if *trans* = 'N' or 'n', and sub(*B*)=*B*(*ib*:*ib*+*k*-1, *jb*:*jb*+*n*-1) otherwise.

Input Parameters

uplo — (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix sub(*C*) is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*C*) is used.

If *uplo* = 'L' or 'l', then the low triangular part of the sub(*C*) is used.

trans — (global) CHARACTER*1. Specifies the operation:

if *trans* = 'N' or 'n', then sub(*C*) := *alpha**sub(*A*)*conjg(sub(*B*)') + conjg(*alpha*)*sub(*B*)*conjg(sub(*A*)') + *beta**sub(*C*);

if *trans* = 'C' or 'c', then sub(*C*) := *alpha**conjg(sub(*A*)')*sub(*A*) + conjg(*alpha*)*conjg(sub(*B*)')*sub(*A*) + *beta**sub(*C*).

n

(global) INTEGER. Specifies the order of the distributed matrix sub(*C*), $n \geq 0$.

k

(global) INTEGER. On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the distributed matrices sub(*A*) and sub(*B*), and on entry with *trans* = 'C' or 'c' , *k* specifies the number of rows of the distributed matrices sub(*A*) and sub(*B*), $k \geq 0$.

alpha

(global)COMPLEX for pcher2k

DOUBLE COMPLEX for pzher2k

Specifies the scalar *alpha*.

a

(local)COMPLEX for pcher2k

DOUBLE COMPLEX for pzher2k

Array, size (*lld_a*, *kla*), where *kla* is LOCq(*ja*+*k*-1) when *trans* = 'N' or 'n', and is LOCq(*ja*+*n*-1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja*

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

b

(local)COMPLEX for pcher2k

DOUBLE COMPLEX for pzher2k

Array, size (*lld_b*, *klb*), where *klb* is LOCq(*jb*+*k*-1) when *trans* = 'N' or 'n', and is LOCq(*jb*+*n*-1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(*B*).

ib, *jb*

(global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.

descb

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *B*.

beta

(global)REAL for pcher2k

DOUBLE PRECISION for pzher2k

Specifies the scalar *beta*.

c

(local)COMPLEX for pcher2k

DOUBLE COMPLEX for pzher2k

Array, size (*lld_c*, LOCq(*jc*+*n*-1)).

Before entry with *uplo* = 'U' or 'u', this array contains *n*-by-*n* upper triangular part of the symmetric distributed matrix sub(*C*) and its strictly lower triangular part is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains *n*-by-*n* lower triangular part of the symmetric distributed matrix sub(*C*) and its strictly upper triangular part is not referenced.

ic, *jc*

(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.

descc

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c

With *uplo* = 'U' or 'u', the upper triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.

With *uplo* = 'L' or 'l', the lower triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.

p?symm

Performs a scalar-matrix-matrix product (one matrix operand is symmetric) and adds the result to a scalar-matrix product for distribute matrices.

Syntax

call pssymm(*side*, *uplo*, *m*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pdsymm(*side*, *uplo*, *m*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pcsymm(*side*, *uplo*, *m*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pzsymm(*side*, *uplo*, *m*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

Include Files

- mkl_pblas.h

Description

The p?symm routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

sub(*C*):=*alpha**sub(*A*)*sub(*B*)+ *beta**sub(*C*),

or

sub(*C*):=*alpha**sub(*B*)*sub(*A*)+ *beta**sub(*C*),

where:

alpha and *beta* are scalars,

sub(*A*) is a symmetric distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*m*-1), if *side* ='L', and sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1), if *side* ='R'.

sub(*B*) and sub(*C*) are *m*-by-*n* distributed matrices.

sub(*B*)=*B*(*ib*:*ib*+*m*-1, *jb*:*jb*+*n*-1), sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1).

Input Parameters

side

(global) CHARACTER*1. Specifies whether the symmetric distributed matrix sub(*A*) appears on the left or right in the operation:

if *side* = 'L' or 'l', then sub(*C*) := *alpha**sub(*A*) *sub(*B*) + *beta**sub(*C*);

if *side* = 'R' or 'r', then sub(*C*) := *alpha**sub(*B*) *sub(*A*) + *beta**sub(*C*).

uplo

(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix sub(*A*) is used:

if *uplo* = 'U' or 'u', then the upper triangular part is used;

if *uplo* = 'L' or 'l', then the lower triangular part is used.

m

(global) INTEGER. Specifies the number of rows of the distribute submatrix sub(*C*), $m \geq 0$.

n

(global) INTEGER. Specifies the number of columns of the distribute submatrix sub(*C*), $m \geq 0$.

alpha

(global)REAL for pssymm

DOUBLE PRECISION for pdsymm

COMPLEX for pcsymm

DOUBLE COMPLEX for pzsymm

Specifies the scalar *alpha*.

a

(local)REAL for pssymm

DOUBLE PRECISION for pdsymm

COMPLEX for pcsymm

DOUBLE COMPLEX for pzsymm

Array, size (*lld_a*, LOCq(*ja*+*na*-1)).

Before entry this array must contain the local pieces of the symmetric distributed matrix sub(*A*), such that when *uplo* = 'U' or 'u', the *na*-by-*na* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and when *uplo* = 'L' or 'l', the *na*-by-*na* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja*

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

b

(local)REAL for pssymm

DOUBLE PRECISION for pdsymm

COMPLEX for pcsymm

DOUBLE COMPLEX for pzsymm

Array, size (*lld_b*, LOCq(*jb*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*B*).

ib, *jb* — (global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.

descb — (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *B*.

beta — (global)REAL for pssymm

DOUBLE PRECISION for pdsymm

COMPLEX for pcsymm

DOUBLE COMPLEX for pzsymm

Specifies the scalar *beta*.

When *beta* is set to zero, then sub(*C*) need not be set on input.

c — (local)REAL for pssymm

DOUBLE PRECISION for pdsymm

COMPLEX for pcsymm

DOUBLE COMPLEX for pzsymm

Array, size (*lld_c*, LOCq(*jc*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*C*).

ic, *jc* — (global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.

descc — (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c — Overwritten by the *m*-by-*n* updated matrix.

p?syrk

Performs a rank-k update of a symmetric distributed matrix.

Syntax

```
call pssyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pdsyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pcsyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pzsyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- mkl_pblas.h

Description

The p?syrk routines perform a distributed matrix-matrix operation defined as

```
sub(C):=alpha*sub(A)*sub(A)'+ beta*sub(C),
```

or

```
sub(C):=alpha*sub(A)'*sub(A)+ beta*sub(C),
```

where:

alpha and *beta* are scalars,

sub(*C*) is an *n*-by-*n* symmetric distributed matrix, sub(*C*)=C(*ic*:*ic*+*n*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*k*-1), if *trans* = 'N' or 'n', and sub(*A*)=*A*(*ia*:*ia*+*k*-1, *ja*:*ja*+*n*-1) otherwise.

Input Parameters

uplo

(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix sub(*C*) is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*C*) is used.

If *uplo* = 'L' or 'l', then the low triangular part of the sub(*C*) is used.

trans

(global) CHARACTER*1. Specifies the operation:

if *trans* = 'N' or 'n', then sub(*C*) := *alpha**sub(*A*)*sub(*A*)' + *beta**sub(*C*);

if *trans* = 'T' or 't', then sub(*C*) := *alpha**sub(*A*)'*sub(*A*) + *beta**sub(*C*).

n

(global) INTEGER. Specifies the order of the distributed matrix sub(*C*), $n \geq 0$.

k

(global) INTEGER. On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the distributed matrix sub(*A*) , and on entry with *trans* = 'T' or 't' , *k* specifies the number of rows of the distributed matrix sub(*A*), $k \geq 0$.

alpha

(global)REAL for pssyrk

DOUBLE PRECISION for pdsyrk

COMPLEX for pcsyrk

DOUBLE COMPLEX for pzsyrk

Specifies the scalar *alpha*.

a

(local)REAL for pssyrk

DOUBLE PRECISION for pdsyrk

COMPLEX for pcsyrk

DOUBLE COMPLEX for pzsyrk

Array, size (*lld_a*, *kla*), where *kla* is LOCq(*ja*+*k*-1) when *trans* = 'N' or 'n', and is LOCq(*ja*+*n*-1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja* — (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca — (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

beta — (global)REAL for pssyrk

DOUBLE PRECISION for pdsyrk

COMPLEX for pcsyrk

DOUBLE COMPLEX for pzsyrk

Specifies the scalar *beta*.

c — (local)REAL for pssyrk

DOUBLE PRECISION for pdsyrk

COMPLEX for pcsyrk

DOUBLE COMPLEX for pzsyrk

Array, size (*lld_c*, LOCq(*jc*+*n*-1)).

Before entry with *uplo* = 'U' or 'u', this array contains *n*-by-*n* upper triangular part of the symmetric distributed matrix sub(*C*) and its strictly lower triangular part is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains *n*-by-*n* lower triangular part of the symmetric distributed matrix sub(*C*) and its strictly upper triangular part is not referenced.

ic, *jc* — (global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.

descc — (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c — With *uplo* = 'U' or 'u', the upper triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.

With *uplo* = 'L' or 'l', the lower triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.

p?syr2k

Performs a rank-2k update of a symmetric distributed matrix.

Syntax

call pssyr2k(*uplo*, *trans*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pdsyr2k(*uplo*, *trans*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pcsyr2k(*uplo*, *trans*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pzsyr2k(*uplo*, *trans*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

Include Files

- mkl_pblas.h

Description

The p?syr2k routines perform a distributed matrix-matrix operation defined as

sub(*C*):=*alpha**sub(*A*)*sub(*B*)'+*alpha**sub(*B*)*sub(*A*)'+ *beta**sub(*C*),

or

sub(*C*):=*alpha**sub(*A*)'*sub(*B*) +*alpha**sub(*B*)'*sub(*A*) + *beta**sub(*C*),

where:

alpha and *beta* are scalars,

sub(*C*) is an *n*-by-*n* symmetric distributed matrix, sub(*C*)=C(*ic*:*ic*+*n*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*k*-1), if *trans* = 'N' or 'n', and sub(*A*)=*A*(*ia*:*ia*+*k*-1, *ja*:*ja*+*n*-1) otherwise.

sub(*B*) is a distributed matrix, sub(*B*)=*B*(*ib*:*ib*+*n*-1, *jb*:*jb*+*k*-1), if *trans* = 'N' or 'n', and sub(*B*)=*B*(*ib*:*ib*+*k*-1, *jb*:*jb*+*n*-1) otherwise.

Input Parameters

uplo

(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix sub(*C*) is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*C*) is used.

If *uplo* = 'L' or 'l', then the low triangular part of the sub(*C*) is used.

trans

(global) CHARACTER*1. Specifies the operation:

if *trans* = 'N' or 'n', then sub(*C*) := *alpha**sub(*A*)*sub(*B*)' + *alpha**sub(*B*)*sub(*A*)' + *beta**sub(*C*);

if *trans* = 'T' or 't', then sub(*C*) := *alpha**sub(*B*)'*sub(*A*) + *alpha**sub(*A*)'*sub(*B*) + *beta**sub(*C*).

n

(global) INTEGER. Specifies the order of the distributed matrix sub(*C*), *n*≥ 0.

k (global) INTEGER. On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the distributed matrices sub(*A*) and sub(*B*), and on entry with *trans* = 'T' or 't' , *k* specifies the number of rows of the distributed matrices sub(*A*) and sub(*B*), *k*≥ 0.

alpha (global)REAL for pssyr2k

DOUBLE PRECISION for pdsyr2k

COMPLEX for pcsyr2k

DOUBLE COMPLEX for pzsyr2k

Specifies the scalar *alpha*.

a (local)REAL for pssyr2k

DOUBLE PRECISION for pdsyr2k

COMPLEX for pcsyr2k

DOUBLE COMPLEX for pzsyr2k

Array, size (*lld_a*, *kla*), where *kla* is LOCq(*ja*+*k*–1) when *trans* = 'N' or 'n', and is LOCq(*ja*+*n*–1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

b (local)REAL for pssyr2k

DOUBLE PRECISION for pdsyr2k

COMPLEX for pcsyr2k

DOUBLE COMPLEX for pzsyr2k

Array, size (*lld_b*, *klb*), where *klb* is LOCq(*jb*+*k*–1) when *trans* = 'N' or 'n', and is LOCq(*jb*+*n*–1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(*B*).

ib, *jb* (global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.

descb (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *B*.

beta (global)REAL for pssyr2k

DOUBLE PRECISION for pdsyr2k

COMPLEX for pcsyr2k

DOUBLE COMPLEX for pzsyr2k

Specifies the scalar *beta*.

c (local)REAL for pssyr2k

	DOUBLE PRECISION for pdsyr2k COMPLEX for pcsyr2k DOUBLE COMPLEX for pzsyr2k Array, size (*lld_c*, LOCq(*jc*+*n*-1)). Before entry with *uplo* = 'U' or 'u', this array contains *n*-by-*n* upper triangular part of the symmetric distributed matrix sub(*C*) and its strictly lower triangular part is not referenced. Before entry with *uplo* = 'L' or 'l', this array contains *n*-by-*n* lower triangular part of the symmetric distributed matrix sub(*C*) and its strictly upper triangular part is not referenced.
ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.
descc	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c	With *uplo* = 'U' or 'u', the upper triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix. With *uplo* = 'L' or 'l', the lower triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.

p?tran

Transposes a real distributed matrix.

Syntax

```
call pstran(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pdtran(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- mkl_pblas.h

Description

The p?tran routines transpose a real distributed matrix. The operation is defined as

```
sub(C):=beta*sub(C) + alpha*sub(A)',
```

where:

alpha and *beta* are scalars,

sub(*C*) is an *m*-by-*n* distributed matrix, sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*m*-1).

Input Parameters

m	(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*C*), *m*≥ 0.
n	(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*C*) , *n*≥ 0.
alpha	(global)REAL for pstran DOUBLE PRECISION for pdtran Specifies the scalar *alpha*.
a	(local)REAL for pstran DOUBLE PRECISION for pdtran Array, size (*lld_a*, LOCq(*ja*+*m*-1)). This array contains the local pieces of the distributed matrix sub(*A*).
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.
beta	(global)REAL for pstran DOUBLE PRECISION for pdtran Specifies the scalar *beta*. When *beta* is equal to zero, then sub(*C*) need not be set on input.
c	(local)REAL for pstran DOUBLE PRECISION for pdtran Array, size (*lld_c*, LOCq(*jc*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*C*).
ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.
descc	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c	Overwritten by the updated submatrix.

p?tranu

Transposes a distributed complex matrix.

Syntax

```
call pctranu(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

```
call pztranu(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- mkl_pblas.h

Description

The p?tranu routines transpose a complex distributed matrix. The operation is defined as

```
sub(C):=beta*sub(C) + alpha*sub(A)',
```

where:

alpha and *beta* are scalars,

sub(*C*) is an *m*-by-*n* distributed matrix, sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*m*-1).

Input Parameters

m	(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*C*), *m*≥ 0.
n	(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*C*) , *n*≥ 0.
alpha	(global)COMPLEX for pctranu DOUBLE COMPLEX for pztranu Specifies the scalar *alpha*.
a	(local)COMPLEX for pctranu DOUBLE COMPLEX for pztranu Array, size (*lld_a*, LOCq(*ja*+*m*-1)). This array contains the local pieces of the distributed matrix sub(*A*).
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.
beta	(global)COMPLEX for pctranu DOUBLE COMPLEX for pztranu Specifies the scalar *beta*. When *beta* is equal to zero, then sub(*C*) need not be set on input.
c	(local)COMPLEX for pctranu DOUBLE COMPLEX for pztranu Array, size (*lld_c*, LOCq(*jc*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*C*).

ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.
descc	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c	Overwritten by the updated submatrix.

p?tranc

Transposes a complex distributed matrix, conjugated.

Syntax

```
call pctranc(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pztranc(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- mkl_pblas.h

Description

The p?tranc routines transpose a complex distributed matrix. The operation is defined as

```
sub(C):=beta*sub(C) + alpha*conjg(sub(A)'),
```

where:

alpha and *beta* are scalars,

sub(*C*) is an *m*-by-*n* distributed matrix, sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*m*-1).

Input Parameters

m	(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*C*), *m*≥ 0.
n	(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*C*) , *n*≥ 0.
alpha	(global)COMPLEX for pctranc DOUBLE COMPLEX for pztranc Specifies the scalar *alpha*.
a	(local)COMPLEX for pctranc DOUBLE COMPLEX for pztranc Array, size (*lld_a*, LOCq(*ja*+*m*-1)). This array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.
beta	(global)COMPLEX for pctranc DOUBLE COMPLEX for pztranc Specifies the scalar *beta*. When *beta* is equal to zero, then sub(*C*) need not be set on input.
c	(local)COMPLEX for pctranc DOUBLE COMPLEX for pztranc Array, size (*lld_c*, LOCq(*jc*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*C*).
ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.
descc	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c	Overwritten by the updated submatrix.

p?trmm

Computes a scalar-matrix-matrix product (one matrix operand is triangular) for distributed matrices.

Syntax

```
call pstrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pdtrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pctrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pztrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
```

Include Files

- mkl_pblas.h

Description

The p?trmm routines perform a matrix-matrix operation using triangular matrices. The operation is defined as

```
sub(B) := alpha*op(sub(A))*sub(B)
```

or

```
sub(B) := alpha*sub(B)*op(sub(A))
```

where:

alpha is a scalar,

sub(*B*) is an *m*-by-*n* distributed matrix, sub(*B*)=*B*(*ib*:*ib*+*m*-1, *jb*:*jb*+*n*-1).

A is a unit, or non-unit, upper or lower triangular distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*m*-1), if *side* = 'L' or 'l', and sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1), if *side* = 'R' or 'r'.

op(sub(*A*)) is one of op(sub(*A*)) = sub(*A*), or op(sub(*A*)) = sub(*A*)', or op(sub(*A*)) = conjg(sub(*A*)').

Input Parameters

side
(global) CHARACTER*1. Specifies whether op(sub(*A*)) appears on the left or right of sub(*B*) in the operation:

if *side* = 'L' or 'l', then sub(*B*) := *alpha**op(sub(*A*))*sub(*B*);

if *side* = 'R' or 'r', then sub(*B*) := *alpha**sub(*B*)*op(sub(*A*)).

uplo
(global) CHARACTER*1. Specifies whether the distributed matrix sub(*A*) is upper or lower triangular:

if *uplo* = 'U' or 'u', then the matrix is upper triangular;

if *uplo* = 'L' or 'l', then the matrix is low triangular.

transa
(global) CHARACTER*1. Specifies the form of op(sub(*A*)) used in the matrix multiplication:

if *transa* = 'N' or 'n', then op(sub(*A*)) = sub(*A*);

if *transa* = 'T' or 't', then op(sub(*A*)) = sub(*A*)' ;

if *transa* = 'C' or 'c', then op(sub(*A*)) = conjg(sub(*A*)').

diag
(global) CHARACTER*1. Specifies whether the matrix sub(*A*) is unit triangular:

if *diag* = 'U' or 'u' then the matrix is unit triangular;

if *diag* = 'N' or 'n', then the matrix is not unit triangular.

m
(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*B*), $m \geq 0$.

n
(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*B*), $n \geq 0$.

alpha
(global)REAL for pstrmm

DOUBLE PRECISION for pdtrmm

COMPLEX for pctrmm

DOUBLE COMPLEX for pztrmm

Specifies the scalar *alpha*.

When *alpha* is zero, then the array*b* need not be set before entry.

a
(local)REAL for pstrmm

DOUBLE PRECISION for pdtrmm

COMPLEX for pctrmm

DOUBLE COMPLEX for pztrmm

Array, size *lld_a* by *ka*, where *ka* is at least LOCq(1, *ja*+*m*-1) when *side* = 'L' or 'l' and is at least LOCq(1, *ja*+*n*-1) when *side* = 'R' or 'r'.

Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix sub(*A*) is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix sub(*A*) is not referenced .

When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix sub(*A*) are not referenced either, but are assumed to be unity.

ia, *ja* — (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca — (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

b — (local)REAL for pstrmm

DOUBLE PRECISION for pdtrmm

COMPLEX for pctrmm

DOUBLE COMPLEX for pztrmm

Array, size (*lld_b*, LOCq(1, *jb*+*n*-1)).

Before entry, this array contains the local pieces of the distributed matrix sub(*B*).

ib, *jb* — (global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.

descb — (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *B*.

Output Parameters

b — Overwritten by the transformed distributed matrix.

p?trsm

Solves a distributed matrix equation (one matrix operand is triangular).

Syntax

```
call pstrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pdtrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pctrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
```

```
call pztrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
```

Include Files

- mkl_pblas.h

Description

The p?trsm routines solve one of the following distributed matrix equations:

```
op(sub(A))*X = alpha*sub(B),
```

or

```
X*op(sub(A)) = alpha*sub(B),
```

where:

alpha is a scalar,

X and sub(*B*) are *m*-by-*n* distributed matrices, sub(*B*)=*B*(*ib*:*ib*+*m*-1, *jb*:*jb*+*n*-1);

A is a unit, or non-unit, upper or lower triangular distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*m*-1), if *side* = 'L' or 'l', and sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1), if *side* = 'R' or 'r';

op(sub(*A*)) is one of op(sub(*A*)) = sub(*A*), or op(sub(*A*)) = sub(*A*)', or op(sub(*A*)) = conjg(sub(*A*)').

The distributed matrix sub(*B*) is overwritten by the solution matrix *X*.

Input Parameters

side

(global) CHARACTER*1. Specifies whether op(sub(*A*)) appears on the left or right of *X* in the equation:

if *side* = 'L' or 'l', then op(sub(*A*))*X = *alpha*sub(*B*);

if *side* = 'R' or 'r', then *X*op(sub(*A*)) = *alpha*sub(*B*).

uplo

(global) CHARACTER*1. Specifies whether the distributed matrix sub(*A*) is upper or lower triangular:

if *uplo* = 'U' or 'u', then the matrix is upper triangular;

if *uplo* = 'L' or 'l', then the matrix is low triangular.

transa

(global) CHARACTER*1. Specifies the form of op(sub(*A*)) used in the matrix equation:

if *transa* = 'N' or 'n', then op(sub(*A*)) = sub(*A*);

if *transa* = 'T' or 't', then op(sub(*A*)) = sub(*A*)';

if *transa* = 'C' or 'c', then op(sub(*A*)) = conjg(sub(*A*)').

diag

(global) CHARACTER*1. Specifies whether the matrix sub(*A*) is unit triangular:

if *diag* = 'U' or 'u' then the matrix is unit triangular;

if *diag* = 'N' or 'n', then the matrix is not unit triangular.

m

(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*B*), $m \geq 0$.

n (global) INTEGER. Specifies the number of columns of the distributed matrix sub(*B*), *n*≥ 0.

alpha (global)REAL for pstrsm

DOUBLE PRECISION for pdtrsm

COMPLEX for pctrsm

DOUBLE COMPLEX for pztrsm

Specifies the scalar *alpha*.

When *alpha* is zero, then *a* is not referenced and *b* need not be set before entry.

a (local)REAL for pstrsm

DOUBLE PRECISION for pdtrsm

COMPLEX for pctrsm

DOUBLE COMPLEX for pztrsm

Array, size *lld_a* by *ka*, where *ka* is at least LOCq(1, *ja*+*m*-1) when *side* = 'L' or 'l' and is at least LOCq(1, *ja*+*n*-1) when *side* = 'R' or 'r'.

Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix sub(*A*) is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix sub(*A*) is not referenced .

When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix sub(*A*) are not referenced either, but are assumed to be unity.

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

b (local)REAL for pstrsm

DOUBLE PRECISION for pdtrsm

COMPLEX for pctrsm

DOUBLE COMPLEX for pztrsm

Array, size (*lld_b*, LOCq(1, *jb*+*n*-1)).

Before entry, this array contains the local pieces of the distributed matrix sub(*B*).

ib, *jb*	(global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.
descb	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *B*.

Output Parameters

b	Overwritten by the solution distributed matrix *X*.

Partial Differential Equations Support

The Intel® oneAPI Math Kernel Library (oneMKL) provides tools for solving Partial Differential Equations (PDE). These tools are Trigonometric Transform interface routines (seeTrigonometric Transform Routines) and Poisson Solver (see Fast Poisson Solver Routines).

Poisson Solver is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The solver is based on the Trigonometric Transform interface, which is, in turn, based on the Intel® oneAPI Math Kernel Library (oneMKL) Fast Fourier Transform (FFT) interface (refer toFourier Transform Functions), optimized for Intel® processors.

Direct use of the Trigonometric Transform routines may be helpful to those who have already implemented their own solvers similar to the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver. As it may be hard enough to modify the original code so as to make it work with Poisson Solver, you are encouraged to use fast (staggered) sine/cosine transforms implemented in the Trigonometric Transform interface to improve performance of your solver.

Both Trigonometric Transform and Poisson Solver routines can be called from C and Fortran, although the interfaces description uses C convention. Fortran users can find routine calls specifics in Calling PDE Support Routines from Fortran.

NOTE
Intel® oneAPI Math Kernel Library (oneMKL) Trigonometric Transform and Poisson Solver routines support Fortran versions starting with Fortran 90.

Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

Notice revision #20201201

Trigonometric Transform Routines

In addition to the Fast Fourier Transform (FFT) interface, described in Fast Fourier Transforms, Intel® oneAPI Math Kernel Library (oneMKL) supports theReal Discrete Trigonometric Transforms (sometimes called real-to-real Discrete Fourier Transforms) interface. In this document, the interface is referred to as TT interface. It implements a group of routines (TT routines) used to compute sine/cosine, staggered sine/cosine, and twice staggered sine/cosine transforms (referred to as staggered2 sine/cosine transforms, for brevity). The TT interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manually tuning routine parameters or just call routines with default parameter values. The current Intel® oneAPI Math Kernel Library (oneMKL) implementation of the TT interface can be used in solving partial differential equations and contains routines that are helpful for Fast Poisson and similar solvers.

To describe the Intel® oneAPI Math Kernel Library (oneMKL) TT interface, the C convention is used. Fortran users should refer toCalling PDE Support Routines from Fortran.

For the list of Trigonometric Transforms currently implemented in Intel® oneAPI Math Kernel Library (oneMKL) TT interface, seeTransforms Implemented.

If you have got used to the FFTW interface (www.fftw.org), you can call the TT interface functions through real-to-real FFTW to Intel® oneAPI Math Kernel Library (oneMKL) wrappers without changing FFTW function calls in your code (refer toFFTW to Intel® MKL Wrappers for FFTW 3.x for details). However, you are strongly encouraged to use the native TT interface for better performance. Another reason why you should use the wrappers cautiously is that TT and the real-to-real FFTW interfaces are not fully compatible and some features of the real-to-real FFTW, such as strides and multidimensional transforms, are not available through wrappers.

Trigonometric Transforms Implemented

TT routines allow computing the following transforms:

Forward sine transform

$$F(k) = \frac{2}{n}\sum_{i=1}^{n-1} f(i)\sin\frac{ki\pi}{n},\ k = 1,\ ...,\ n-1$$

Backward sine transform

$$f(i) = \sum_{k=1}^{n-1} F(k)\sin\frac{ki\pi}{n},\ i = 1,\ ...,\ n-1$$

Forward staggered sine transform

$$F(k) = \frac{1}{n}\sin\frac{(2k-1)\pi}{2}f(n) + \frac{2}{n}\sum_{i=1}^{n-1} f(i)\sin\frac{(2k-1)i\pi}{2n},\ k = 1,\ ...,\ n$$

Backward staggered sine transform

$$f(i) = \sum_{k=1}^{n} F(k)\sin\frac{(2k-1)i\pi}{2n},\ i = 1,\ ...,\ n$$

Forward staggered2 sine transform

$$F(k) = \frac{2}{n}\sum_{i=1}^{n} f(i)\sin\frac{(2k-1)(2i-1)\pi}{4n},\ k = 1,\ ...,\ n$$

Backward staggered2 sine transform

$$f(i) = \sum_{k=1}^{n} F(k)\sin\frac{(2k-1)(2i-1)\pi}{4n},\ i = 1,\ ...,\ n$$

Forward cosine transform

$$F(k) = \frac{1}{n}[f(o) + f(n)\cos k\pi] + \frac{2}{n}\sum_{i=1}^{n-1} f(i)\cos\frac{ki\pi}{n},\ k = 0,\ ...,\ n$$

Backward cosine transform

$$f(i) = \frac{1}{2}[F(o) + F(n)\cos i\pi] + \sum_{k=1}^{n-1} F(k)\cos\frac{ki\pi}{n},\ i = 0,\ ...,\ n$$

Forward staggered cosine transform

$$F(k) = \frac{1}{n}f(0) + \frac{2}{n}\sum_{i=1}^{n-1} f(i)\cos\frac{(2k+1)i\pi}{2n},\ k = 0,\ ...,\ n-1$$

Backward staggered cosine transform

$$f(i) = \sum_{k=0}^{n-1} F(k) \cos\frac{(2k+1)i\pi}{2n},\ i = 0,\ ...,\ n-1$$

Forward staggered2 cosine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^{n} f(i) \cos\frac{(2k-1)(2i-1)\pi}{4n},\ k = 1,\ ...,\ n$$

Backward staggered2 cosine transform

$$f(i) = \sum_{k=1}^{n} F(k) \cos\frac{(2k-1)(2i-1)\pi}{4n},\ i = 1,\ ...,\ n$$

NOTE
The size of the transform *n* can be any integer greater or equal to 2.

Sequence of Invoking TT Routines

Computation of a transform using TT interface is conceptually divided into four steps, each of which is performed via a dedicated routine. Table "TT Interface Routines" lists the routines and briefly describes their purpose and use.

Most TT routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "`s`" and "`d`". The wildcard "`?`" stands for either of these symbols in routine names.

TT Interface Routines

Routine	Description
`?_init_trig_transform`	Initializes basic data structures of Trigonometric Transforms.
`?_commit_trig_transform`	Checks consistency and correctness of user-defined data and creates a data structure to be used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface[1].
`?_forward_trig_transform` `?_backward_trig_transform`	Computes a forward/backward Trigonometric Transform of a specified type using the appropriate formula (see Transforms Implemented).
`free_trig_transform`	Releases the memory used by a data structure needed for calling FFT interface[1].

[1]TT routines call Intel® oneAPI Math Kernel Library (oneMKL) FFT interface for better performance.

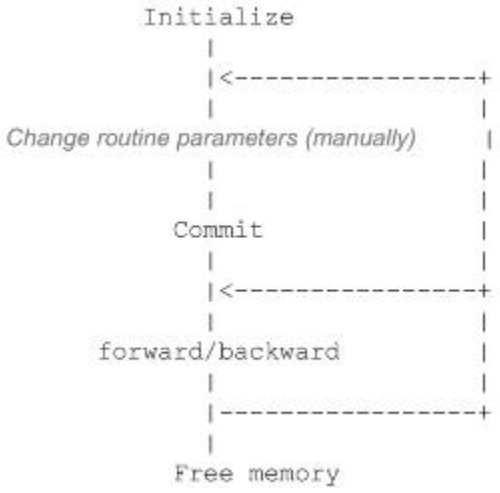
To find a transformed vector for a particular input vector only once, the Intel® oneAPI Math Kernel Library (oneMKL) TT interface routines are normally invoked in the order in which they are listed inTable "TT Interface Routines".

NOTE
Though the order of invoking TT routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in Figure "Typical Order of Invoking TT Interface Routines" indicates the typical order in which TT interface routines can be invoked in a general case (prefixes and suffixes in routine names are omitted).

__border__top

Typical Order of Invoking TT Interface Routines



A general scheme of using TT routines for double-precision computations is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names.

```
...
    d_init_trig_transform(&n, &tt_type, ipar, dpar, &ir);
/* Change parameters in ipar if necessary. */
/* Note that the result of the Transform will be in f. If you want to preserve the data stored
in f,
save it to another location before the function call below */
    d_commit_trig_transform(f, &handle, ipar, dpar, &ir);
    d_forward_trig_transform(f, &handle, ipar, dpar, &ir);
    d_backward_trig_transform(f, &handle, ipar, dpar, &ir);
    free_trig_transform(&handle, ipar, &ir);
/* here the user may clean the memory used by f, dpar, ipar */
...
```

You can find examples of code that uses TT interface routines to solve one-dimensional Helmholtz problem in the `examples\pdettf\source` folderin your Intel® oneAPI Math Kernel Library (oneMKL) directory.

Trigonometric Transform Interface Description

All types in this documentation are either standard C types `float` and `double` or `MKL_INT` integer type. Fortran users can call the routines with `REAL` and `DOUBLE PRECISION` types of floating-point values and `INTEGER` or `INTEGER`*8 integer type depending on the programming interface (LP64 or ILP64). To better understand usage of the types, see examples in the `examples\pdettf\source` folderin your Intel® oneAPI Math Kernel Library (oneMKL) directory.

Routine Options

All TT routines use parameters to pass various options to one another. These parameters are arrays *ipar*, *dpar* and *spar*. Values for these parameters should be specified very carefully (see Common Parameters). You can change these values during computations to meet your needs.

WARNING
To avoid failure or incorrect results, you must provide correct and consistent parameters to the routines.

User Data Arrays

TT routines take arrays of user data as input. For example, user arrays are passed to the routine `d_forward_trig_transform`to compute a forward Trigonometric Transform. To minimize storage requirements and improve the overall run-time efficiency, Intel® oneAPI Math Kernel Library (oneMKL) TT routines do not make copies of user input arrays.

> **NOTE**
> If you need a copy of your input data arrays, you must save them yourself.

For better performance, align your data arrays as recommended in the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* (search the document for coding techniques to improve performance).

TT Routines

The section gives detailed description of TT routines, their syntax, parameters and values they return. Double-precision and single-precision versions of the same routine are described together.

TT routines call Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (described inFFT Functions), which enhances performance of the routines.

?_init_trig_transform

Initializes basic data structures of a Trigonometric Transform.

Syntax

```
void d_init_trig_transform(MKL_INT *n, MKL_INT *tt_type, MKL_INT ipar[], double dpar[],
MKL_INT *stat);
```

```
void s_init_trig_transform(MKL_INT *n, MKL_INT *tt_type, MKL_INT ipar[], float spar[],
MKL_INT *stat);
```

Include Files

- `mkl_trig_transforms.f90`

Input Parameters

n	`MKL_INT*`. Contains the size of the problem, which should be a positive integer greater than 1. Note that data vector of the transform, which other TT routines will use, must have size *n*+1 for all but staggered2 transforms. Staggered2 transforms require the vector of size *n*.
tt_type	`MKL_INT*`. Contains the type of transform to compute, defined via a set of named constants. The following constants are available in the current implementation of TT interface: `MKL_SINE_TRANSFORM`, `MKL_STAGGERED_SINE_TRANSFORM`, `MKL_STAGGERED2_SINE_TRANSFORM`; `MKL_COSINE_TRANSFORM`, `MKL_STAGGERED_COSINE_TRANSFORM`, `MKL_STAGGERED2_COSINE_TRANSFORM`.

Output Parameters

ipar	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
dpar	double array of size 5*n*/2+2. Contains double-precision data needed for Trigonometric Transform computations.
spar	float array of size 5*n*/2+2. Contains single-precision data needed for Trigonometric Transform computations.
stat	MKL_INT*. Contains the routine completion status, which is also written to *ipar[6]*. The status should be 0 to proceed to other TT routines.

Description

The ?_init_trig_transform routine initializes basic data structures for Trigonometric Transforms of appropriate precision. After a call to ?_init_trig_transform, all subsequently invoked TT routines use values of *ipar* and *dpar* (*spar*) array parameters returned by ?_init_trig_transform. The routine initializes the entire array *ipar*. In the *dpar* or *spar* array, ?_init_trig_transform initializes elements that do not depend upon the type of transform. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to Common Parameters. You can skip a call to the initialization routine in your code. For more information, see Caveat on Parameter Modifications.

Return Values

stat= 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this *stat* value.
stat= -99999	The routine failed to complete the task.

?_commit_trig_transform

Checks consistency and correctness of user's data as well as initializes certain data structures required to perform the Trigonometric Transform.

Syntax

```
void d_commit_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);
```

```
void s_commit_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

Include Files

- mkl_trig_transforms.f90

Input Parameters

f	double for d_commit_trig_transform, float for s_commit_trig_transform,

array of size *n* for staggered2 transforms and of size *n*+1 for all other transforms, where *n* is the size of the problem. Contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:

- *f*[0] and *f*[*n*] for sine transforms
- *f*[*n*] for staggered cosine transforms
- *f*[0] for staggered sine transforms.

Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. These restrictions meet the requirements of the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver, which the TT interface is primarily designed for (for details, seeFast Poisson Solver Routines).

ipar — `MKL_INT` array of size 128. Contains integer data needed for Trigonometric Transform computations.

dpar — `double` array of size 5*n*/2+2. Contains double-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.

spar — `float` array of size 5*n*/2+2. Contains single-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.

Output Parameters

handle — `DFTI_DESCRIPTOR_HANDLE*`. The data structure used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer toFFT Functions).

ipar — Contains integer data needed for Trigonometric Transform computations. On output, *ipar[6]* is updated with the *stat* value.

dpar — Contains double-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.

spar — Contains single-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.

stat — `MKL_INT*`. Contains the routine completion status, which is also written to *ipar[6]*.

Description

The routine `?_commit_trig_transform` checks consistency and correctness of the parameters to be passed to the transform routines `?_forward_trig_transform` and/or `?_backward_trig_transform`. The routine also initializes the following data structures: *handle*, *dpar* in case of `d_commit_trig_transform`, and *spar* in case of `s_commit_trig_transform`. The `?_commit_trig_transform` routine initializes only those elements of *dpar* or *spar* that depend upon the type of transform, defined in the `?_init_trig_transform` routine and passed to `?_commit_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to Common Parameters. The routine performs only a basic check for correctness and consistency

of the parameters. If you are going to modify parameters of TT routines, see Caveat on Parameter Modifications. Unlike `?_init_trig_transform`, you must call the `?_commit_trig_transform` routine in your code.

Return Values

stat= 11	The routine produced some warnings and made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning *ipar[6]*=0 if you are sure that the parameters are correct.
stat= 10	The routine made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning *ipar[6]*=0 if you are sure that the parameters are correct.
stat= 1	The routine produced some warnings. You may proceed with computations by assigning *ipar[6]*=0 if you are sure that the parameters are correct.
stat= 0	The routine completed the task normally.
stat= -100	The routine stopped for any of the following reasons: • An error in the user's data was encountered. • Data in *ipar*, *dpar* or *spar* parameters became incorrect and/or inconsistent as a result of modifications.
stat= -1000	The routine stopped because of an FFT interface error.
stat= -10000	The routine stopped because the initialization failed to complete or the parameter *ipar[0]* was altered by mistake.

NOTE
Although positive values of *stat* usually indicate minor problems with the input data and Trigonometric Transform computations can be continued, you are highly recommended to investigate the problem first and achieve *stat*=0.

?_forward_trig_transform

Computes the forward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_forward_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);
```

```
void s_forward_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

Include Files

- `mkl_trig_transforms.f90`

Input Parameters

f	`double` for `d_forward_trig_transform`, `float` for `s_forward_trig_transform`, array of size *n* for staggered2 transforms and of size *n*+1 for all other transforms, where *n* is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors: • *f*[0] and *f*[*n*] for sine transforms • *f*[*n*] for staggered cosine transforms • *f*[0] for staggered sine transforms. Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver, which the TT interface is primarily designed for (for details, seeFast Poisson Solver Routines).
handle	`DFTI_DESCRIPTOR_HANDLE*`. The data structure used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, seeFFT Functions).
ipar	`MKL_INT` array of size 128. Contains integer data needed for Trigonometric Transform computations.
dpar	`double` array of size 5*n*/2+2. Contains double-precision data needed for Trigonometric Transform computations.
spar	`float` array of size 5*n*/2+2. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

f	Contains the transformed vector on output.
ipar	Contains integer data needed for Trigonometric Transform computations. On output, *ipar[6]* is updated with the *stat* value.
stat	`MKL_INT*`. Contains the routine completion status, which is also written to *ipar[6]*.

Description

The routine computes the forward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_forward_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to Common Parameters. The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in Transforms Implemented. The routine replaces the input vector *f* with the transformed vector.

NOTE
If you need a copy of the data vector *f* to be transformed, make the copy before calling the ?_forward_trig_transform routine.

Return Values

stat= 0	The routine completed the task normally.
stat= -100	The routine stopped for any of the following reasons: • An error in the user's data was encountered. • Data in *ipar*, *dpar* or *spar* parameters became incorrect and/or inconsistent as a result of modifications.
stat= -1000	The routine stopped because of an FFT interface error.
stat= -10000	The routine stopped because its commit step failed to complete or the parameter *ipar[0]* was altered by mistake.

?_backward_trig_transform

Computes the backward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_backward_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);
```

```
void s_backward_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

Include Files

- mkl_trig_transforms.f90

Input Parameters

f	double for d_backward_trig_transform, float for s_backward_trig_transform, array of size *n* for staggered2 transforms and of size *n*+1 for all other transforms, where *n* is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors: • *f*[0] and *f*[*n*] for sine transforms • *f*[*n*] for staggered cosine transforms • *f*[0] for staggered sine transforms. Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver, which the TT interface is primarily designed for (for details, seeFast Poisson Solver Routines).

handle	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, seeFFT Functions).
ipar	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
dpar	double array of size 5*n*/2+2. Contains double-precision data needed for Trigonometric Transform computations.
spar	float array of size 5*n*/2+2. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

f	Contains the transformed vector on output.
ipar	Contains integer data needed for Trigonometric Transform computations. On output, *ipar[6]* is updated with the *stat* value.
stat	MKL_INT*. Contains the routine completion status, which is also written to *ipar[6]*.

Description

The routine computes the backward Trigonometric Transform of type defined in the ?_init_trig_transform routine and passed to ?_backward_trig_transform with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called ?_init_trig_transform routine. The other data that facilitates the computation is created by ?_commit_trig_transform and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to Common Parameters. The routine has a commit step, which calls the ?_commit_trig_transform routine. The transform is computed according to formulas given in Transforms Implemented. The routine replaces the input vector *f* with the transformed vector.

NOTE
If you need a copy of the data vector *f* to be transformed, make the copy before calling the ?_backward_trig_transform routine.

Return Values

stat= 0	The routine completed the task normally.
stat= -100	The routine stopped for any of the following reasons: • An error in the user's data was encountered. • Data in *ipar*, *dpar* or *spar* parameters became incorrect and/or inconsistent as a result of modifications.
stat= -1000	The routine stopped because of an FFT interface error.
stat= -10000	The routine stopped because its commit step failed to complete or the parameter *ipar[0]* was altered by mistake.

free_trig_transform

Cleans the memory allocated for the data structure used by the FFT interface.

Syntax

```
void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], MKL_INT *stat);
```

Include Files

- mkl_trig_transforms.f90

Input Parameters

ipar	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
handle	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer toFFT Functions).

Output Parameters

handle	The data structure used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface. Memory allocated for the structure is released on output.
ipar	Contains integer data needed for Trigonometric Transform computations. On output, *ipar[6]* is updated with the *stat* value.
stat	MKL_INT*. Contains the routine completion status, which is also written to *ipar[6]*.

Description

The free_trig_transform routine cleans the memory used by the *handle*structure, needed for Intel® oneAPI Math Kernel Library (oneMKL) FFT functions. To release the memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

stat= 0	The routine completed the task normally.
stat= -1000	The routine stopped because of an FFT interface error.
stat= -99999	The routine failed to complete the task.

Common Parameters of the Trigonometric Transforms

This section provides description of array parameters that hold TT routine options: *ipar*, *dpar* and *spar*.

NOTE
Initial values are assigned to the array parameters by the appropriate ?_init_trig_transform and ?_commit_trig_transform routines.

ipar	MKL_INT array of size 128, holds integer data needed for Trigonometric Transform computations. Its elements are described in Table "Elements of the ipar Array":

Elements of the ipar Array

Index	Description
0	Contains the size of the problem to solve. The ?_init_trig_transform routine sets *ipar[0]*=*n*, and all subsequently called TT routines use *ipar[0]* as the size of the transform.
1	Contains error messaging options: • *ipar[1]*=-1 indicates that all error messages will be printed to the file MKL_Trig_Transforms_log.txt in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • *ipar[1]*=0 indicates that no error messages will be printed. • *ipar[1]*=1 (default) indicates that all error messages will be printed to the preconnected default output device (usually, screen). In case of errors, each TT routine assigns a non-zero value to *stat* regardless of the *ipar[1]* setting.
2	Contains warning messaging options: • *ipar[2]*=-1 indicates that all warning messages will be printed to the file MKL_Trig_Transforms_log.txt in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • *ipar[2]*=0 indicates that no warning messages will be printed. • *ipar[2]*=1 (default) indicates that all warning messages will be printed to the preconnected default output device (usually, screen). In case of warnings, the *stat* parameter will acquire a non-zero value regardless of the *ipar[2]* setting.
3 through 4	Reserved for future use.
5	Contains the type of the transform. The ?_init_trig_transform routine sets *ipar[5]*=*tt_type*, and all subsequently called TT routines use *ipar[5]* as the type of the transform.
6	Contains the *stat* value returned by the last completed TT routine. Used to check that the previous call to a TT routine completed with *stat*=0.
7	Informs the ?_commit_trig_transform routines whether to initialize data structures *dpar* (*spar*) and *handle*. *ipar[7]*=0 indicates that the routine should skip the initialization and only check correctness and consistency of the parameters. Otherwise, the routine initializes the data structures. The default value is 1. The possibility to check correctness and consistency of input data without initializing data structures *dpar*, *spar* and *handle* enables avoiding performance losses in a repeated use of the same transform for different data vectors. Note that you can benefit from the opportunity that *ipar[7]* gives only if you are sure to have supplied proper tolerance value in the *dpar* or *spar* array. Otherwise, avoid tuning this parameter.
8	Contains message style options for TT routines. If *ipar[8]*=0 then TT routines print all error and warning messages in Fortran-style notations. The default value is 1.

Index	Description
	When specifying message style options, be aware that by default, numbering of elements in Fortran arrays starts at 1. The use of *ipar[8]* enables you to view messages in a more convenient style.
9	Specifies the number of OpenMP threads to run TT routines in the OpenMP environment of the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver. The default value is 1. You are highly recommended not to alter this value. See alsoCaveat on Parameter Modifications.
10	Specifies the mode of compatibility with FFTW. The default value is 0. Set the value to 1 to invoke compatibility with FFTW. In the latter case, results will not be normalized, because FFTW does not do this. It is highly recommended not to alter this value, but rather use real-to-real FFTW to MKL wrappers, described in FFTW to Intel® MKL Wrappers for FFTW 3.x. See also Caveat on Parameter Modifications.
11 through 127	Reserved for future use.

NOTE
While you can declare the *ipar* array as `MKL_INT ipar[11]`, for future compatibility you should declare *ipar* as `MKL_INT ipar[128]`.

Arrays *dpar* and *spar* are the same except in the data precision:

dpar	`double` array of size 5*n*/2+2, holds data needed for double-precision routines to perform TT computations. This array is initialized in the `d_init_trig_transform` and `d_commit_trig_transform` routines.
spar	`float` array of size 5*n*/2+2, holds data needed for single-precision routines to perform TT computations. This array is initialized in the `s_init_trig_transform` and `s_commit_trig_transform` routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in Table "Elements of the dpar and spar Arrays":

Elements of the dpar and spar Arrays

Index	Description
0	Contains the first absolute tolerance used by the appropriate `?_commit_trig_transform` routine. For a staggered cosine or a sine transform, *f[n]* should be equal to 0.0 and for a staggered sine or a sine transform, *f[0]* should be equal to 0.0. The `?_commit_trig_transform` routine checks whether absolute values of these parameters are below *dpar[0]*n* or *spar[0]*n*, depending on the routine precision. To suppress warnings resulting from tolerance checks, set *dpar[0]* or *spar[0]* to a sufficiently large number.
1	Reserved for future use.
2 through 5*n*/2+1	Contain tabulated values of trigonometric functions. Contents of the elements depend upon the type of transform *tt_type*, set up in the `?_commit_trig_transform` routine: • If *tt_type*=`MKL_SINE_TRANSFORM`, the transform uses only the first *n*/2 array elements, which contain tabulated sine values. • If *tt_type*=`MKL_STAGGERED_SINE_TRANSFORM`, the transform uses only the first 3*n*/2 array elements, which contain tabulated sine and cosine values. • If *tt_type*=`MKL_STAGGERED2_SINE_TRANSFORM`, the transform uses all the 5*n*/2 array elements, which contain tabulated sine and cosine values.

Index	Description
	• If *tt_type*=MKL_COSINE_TRANSFORM, the transform uses only the first *n* array elements, which contain tabulated cosine values. • If *tt_type*=MKL_STAGGERED_COSINE_TRANSFORM, the transform uses only the first 3*n*/2 elements, which contain tabulated sine and cosine values. • If *tt_type*=MKL_STAGGERED2_COSINE_TRANSFORM, the transform uses all the 5*n*/2 elements, which contain tabulated sine and cosine values.

NOTE
To save memory, you can define the array size depending upon the type of transform.

Caveat on Parameter Modifications

Flexibility of the TT interface enables you to skip a call to the ?_init_trig_transform routine and to initialize the basic data structures explicitly in your code. You may also need to modify the contents of *ipar*, *dpar* and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the ?_commit_trig_transform routine; however, this does not ensure the correct result of a transform but only reduces the chance of errors or wrong results.

NOTE
To supply correct and consistent parameters to TT routines, you should have considerable experience in using the TT interface and good understanding of elements that the *ipar*, *spar* and *dpar* arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail to compute a transform using TT routines after the parameter modifications. In cases like these, refer for technical support at http://www.intel.com/software/products/support/ .

WARNING
The only way that ensures proper computation of the Trigonometric Transforms is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar* and *spar* arrays unless a strong need arises.

Trigonometric Transform Implementation Details

Several aspects of the Intel® oneAPI Math Kernel Library (oneMKL) TT interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, Intel® oneAPI Math Kernel Library (oneMKL) provides you with the TT language-specific header file to include in your code:

- mkl_trig_transforms.f90, to be used together with mkl_dfti.f90.

NOTE

- Intel® oneAPI Math Kernel Library (oneMKL) TT interface supports Fortran versions starting with Fortran 90.
- Use of the Intel® oneAPI Math Kernel Library (oneMKL) TT software without including the above language-specific header files is not supported.

Header File

The header file below defines the following function prototypes:

```
SUBROUTINE D_INIT_TRIG_TRANSFORM(n, tt_type, ipar, dpar, stat)
    INTEGER, INTENT(IN) :: n, tt_type
    INTEGER, INTENT(INOUT) :: ipar(*)

END SUBROUTINE FREE_TRIG_TRANSFORM
```

Fortran specifics of the TT routines usage are similar for all Intel® oneAPI Math Kernel Library (oneMKL) PDE support tools and described inCalling PDE Support Routines from Fortran.

Fast Poisson Solver Routines

In addition to the Real Discrete Trigonometric Transforms (TT) interface (refer to Trigonometric Transform Routines), Intel® oneAPI Math Kernel Library (oneMKL) supports thethe Poisson Solver interface. This interface implements a group of routines (Poisson Solver routines) used to compute a solution of Laplace, Poisson, and Helmholtz problems of a special kind using discrete Fourier transforms. Laplace and Poisson problems are special cases of a more general Helmholtz problem. The problems that are solved by the Poisson Solver interface are defined more exactly in Poisson Solver Implementation. The Poisson Solver interface provides much flexibility of use: you can call routines with the default parameter values or adjust routines to your particular needs by manually tuning routine parameters. You can adjust the style of error and warning messages to a Fortrannotation by setting up a dedicated parameter. This adds convenience to debugging, because you can read information in the way that is natural for your code. The Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver interface currently contains only routines that implement the following solvers:

- Fast Laplace, Poisson and Helmholtz solvers in a Cartesian coordinate system
- Fast Poisson and Helmholtz solvers in a spherical coordinate system.

To describe the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver interface, the C convention is used. Fortran usage specifics can be found inCalling PDE Support Routines from Fortran.

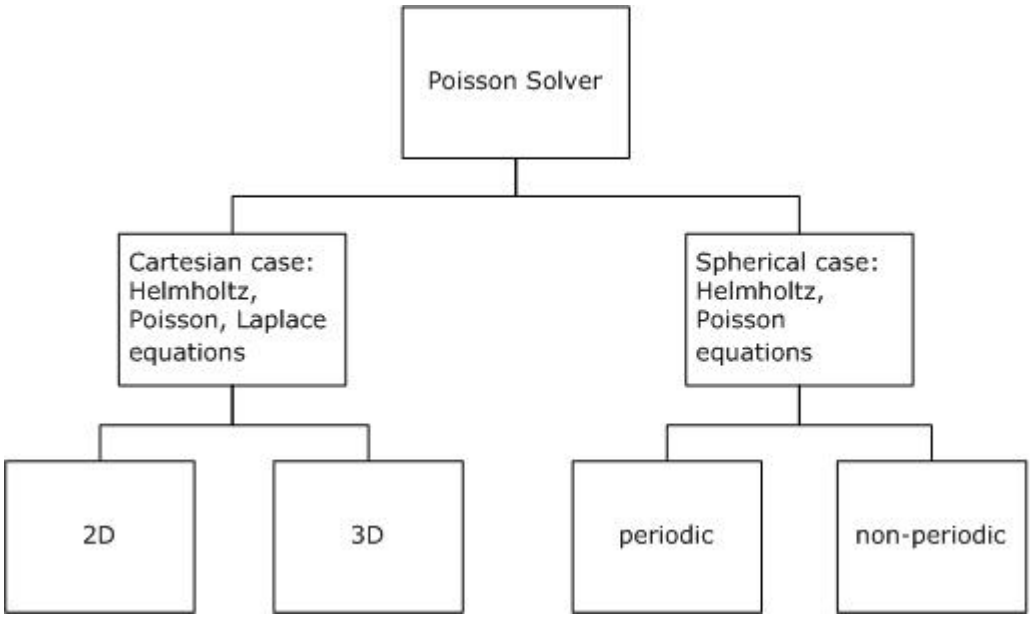
NOTE
Fortran users should keep in mind that array indices in Fortran start at 1 instead of 0, as they do in C.

Poisson Solver Implementation

Poisson Solver routines enable approximate solving of certain two-dimensional and three-dimensional problems. Figure "Structure of the Poisson Solver" shows the general structure of the Poisson Solver.

__border__top

Structure of the Poisson Solver



NOTE
Although in the Cartesian case, both periodic and non-periodic solvers are also supported, they use the same interfaces.

Sections below provide details of the problems that can be solved using Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver.

Two-Dimensional Problems

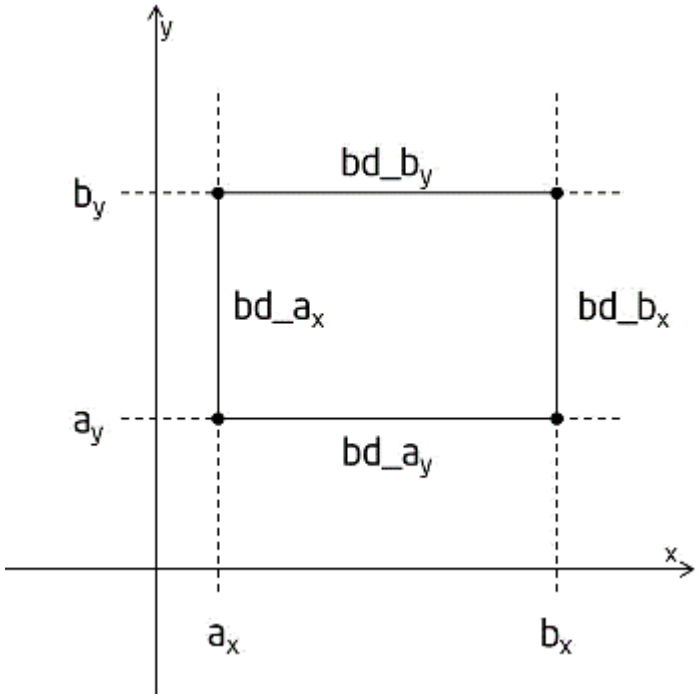
Notational Conventions

The Poisson Solver interface description uses the following notation for boundaries of a rectangular domain $a_x < x < b_x$, $a_y < y < b_y$ on a Cartesian plane:

$bd\_a_x = \{x = a_x, a_y \le y \le b_y\}$, $bd\_b_x = \{x = b_x, a_y \le y \le b_y\}$

$bd\_a_y = \{a_x \le x \le b_x, y = a_y\}$, $bd\_b_y = \{a_x \le x \le b_x, y = b_y\}$.

The following figure shows these boundaries:



The wildcard "+" may stand for any of the symbols a_x, b_x, a_y, b_y, so *bd_+* denotes any of the above boundaries.

The Poisson Solver interface description uses the following notation for boundaries of a rectangular domain $a_\varphi < \varphi < b_\varphi$, $a_\theta < \theta < b_\theta$ on a sphere $0 \le \varphi \le 2\pi$, $0 \le \theta \le \pi$:

bd_a$_\varphi$ = {$\varphi = a_\varphi$, $a_\theta \le \theta \le b_\theta$}, *bd_b*$_\varphi$ = {$\varphi = b_\varphi$, $a_\theta \le \theta \le b_\theta$},

bd_a$_\theta$ = {$a_\varphi \le \varphi \le b_\varphi$, $\theta = a_\theta$}, *bd_b*$_\theta$ = {$a_\varphi \le \varphi \le b_\varphi$, $\theta = b_\theta$}.

The wildcard "~" may stand for any of the symbols a_φ, b_φ, a_θ, b_θ, so *bd_~* denotes any of the above boundaries.

Two-dimensional Helmholtz problem on a Cartesian plane

The two-dimensional (2D) Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} + qu = f(x,y),\ q = const \ge 0$$

in a rectangle, that is, a rectangular domain $a_x < x < b_x$, $a_y < y < b_y$, with one of the following boundary conditions on each boundary *bd_+*:

- The Dirichlet boundary condition

  $$u(x,y) = G(x,y)$$
- The Neumann boundary condition

  $$\frac{\partial u}{\partial n}(x,y) = g(x,y)$$

  where

  $n = -x$ on *bd_a*$_x$, $n = x$ on *bd_b*$_x$,

  $n = -y$ on *bd_a*$_y$, $n = y$ on *bd_b*$_y$.
- Periodic boundary conditions

  $$u(a_x,y) = u(b_x,y),\ \frac{\partial}{\partial x}u(a_x,y) = \frac{\partial}{\partial x}u(b_x,y),$$

$$u(x, a_y) = u(x, b_y),\ \frac{\partial}{\partial y}u(x, a_y) = \frac{\partial}{\partial y}u(x, b_y).$$

Two-dimensional Poisson problem on a Cartesian plane

The Poisson problem is a special case of the Helmholtz problem, when *q*=0. The 2D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = f(x, y)$$

in a rectangle $a_x < x < b_x$, $a_y < y < b_y$ with the Dirichlet, Neumann, or periodic boundary conditions on each boundary *bd_+*. In case of a problem with the Neumann boundary condition on the entire boundary, you can find the solution of the problem only up to a constant. In this case, the Poisson Solver will compute the solution that provides the minimal Euclidean norm of a residual.

Two-dimensional (2D) Laplace problem on a Cartesian plane

The Laplace problem is a special case of the Helmholtz problem, when *q*=0 and *f(x, y)*=0. The 2D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

in a rectangle $a_x < x < b_x$, $a_y < y < b_y$ with the Dirichlet, Neumann, or periodic boundary conditions on each boundary *bd_+*.

Helmholtz problem on a sphere

The Helmholtz problem on a sphere is to find an approximate solution of the Helmholtz equation

$$-\Delta_s u + qu = f,\ q = const \geq 0,$$

$$\Delta_s = \frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\phi^2} + \frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right)$$

in a domain bounded by angles $a_\varphi \leq \varphi \leq b_\varphi$, $a_\theta \leq \theta \leq b_\theta$ (spherical rectangle), with boundary conditions for particular domains listed in Table "Details of Helmholtz Problem on a Sphere".

Details of Helmholtz Problem on a Sphere

Domain on a sphere	Boundary condition	Periodic/non-periodic case
Rectangular, that is, $b_\varphi - a_\varphi < 2\pi$ and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on each boundary *bd_~*	*non-periodic*
Where $a_\varphi = 0$, $b_\varphi = 2\pi$, and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on the boundaries *bd_*a_θ and *bd_*b_θ	*periodic*
Entire sphere, that is, $a_\varphi = 0$, $b_\varphi = 2\pi$, $a_\theta = 0$, and $b_\theta = \pi$	Boundary condition $\left(\sin\theta\frac{\partial u}{\partial\theta}\right) = 0^{\theta \to 0}_{\theta \to \pi}$ at the poles	*periodic*

Poisson problem on a sphere

The Poisson problem is a special case of the Helmholtz problem, when *q*=0. The Poisson problem on a sphere is to find an approximate solution of the Poisson equation

$$-\Delta_s u = f,\ \Delta_s = \frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\phi^2} + \frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right)$$

in a spherical rectangle $a_\varphi \le \varphi \le b_\varphi$, $a_\theta \le \theta \le b_\theta$ in cases listed in Table "Details of Helmholtz Problem on a Sphere". The solution to the Poisson problem on the entire sphere can be found up to a constant only. In this case, Poisson Solver will compute the solution that provides the minimal Euclidean norm of a residual.

Approximation of 2D problems

To find an approximate solution for any of the 2D problems, in the rectangular domain a uniform mesh can be defined for the Cartesian case as:

$$\left\{x_i = a_x + ih_x, y_j = a_y + jh_y\right\},$$

$$i = 0, ..., n_x,\ j = 0, ..., n_y,\ h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}$$

and for the spherical case as:

$$\left\{\phi_i = a_\phi + ih_\phi, \theta_j = a_\theta + jh_\theta\right\},$$

$$i = 0, ..., n_\phi,\ j = 0, ..., n_\theta,\ h_\phi = \frac{b_\phi - a_\phi}{n_\phi}, h_\theta = \frac{b_\theta - a_\theta}{n_\theta}.$$

The Poisson Solver uses the standard five-point finite difference approximation on this mesh to compute the approximation to the solution:

- In the Cartesian case, the values of the approximate solution will be computed in the mesh points (x_i , y_j) provided that you can supply the values of the right-hand side *f(x, y)* in these points and the values of the appropriate boundary functions *G(x, y)* and/or *g(x,y)* in the mesh points laying on the boundary of the rectangular domain.
- In the spherical case, the values of the approximate solution will be computed in the mesh points (φ_i , θ_j) provided that you can supply the values of the right-hand side $f(\varphi, \theta)$ in these points.

> **NOTE**
> The number of mesh intervals n_φ in the φ direction of a spherical mesh must be even in the periodic case. The Poisson Solver does not support spherical meshes that do not meet this condition.

Three-Dimensional Problems

Notational Conventions

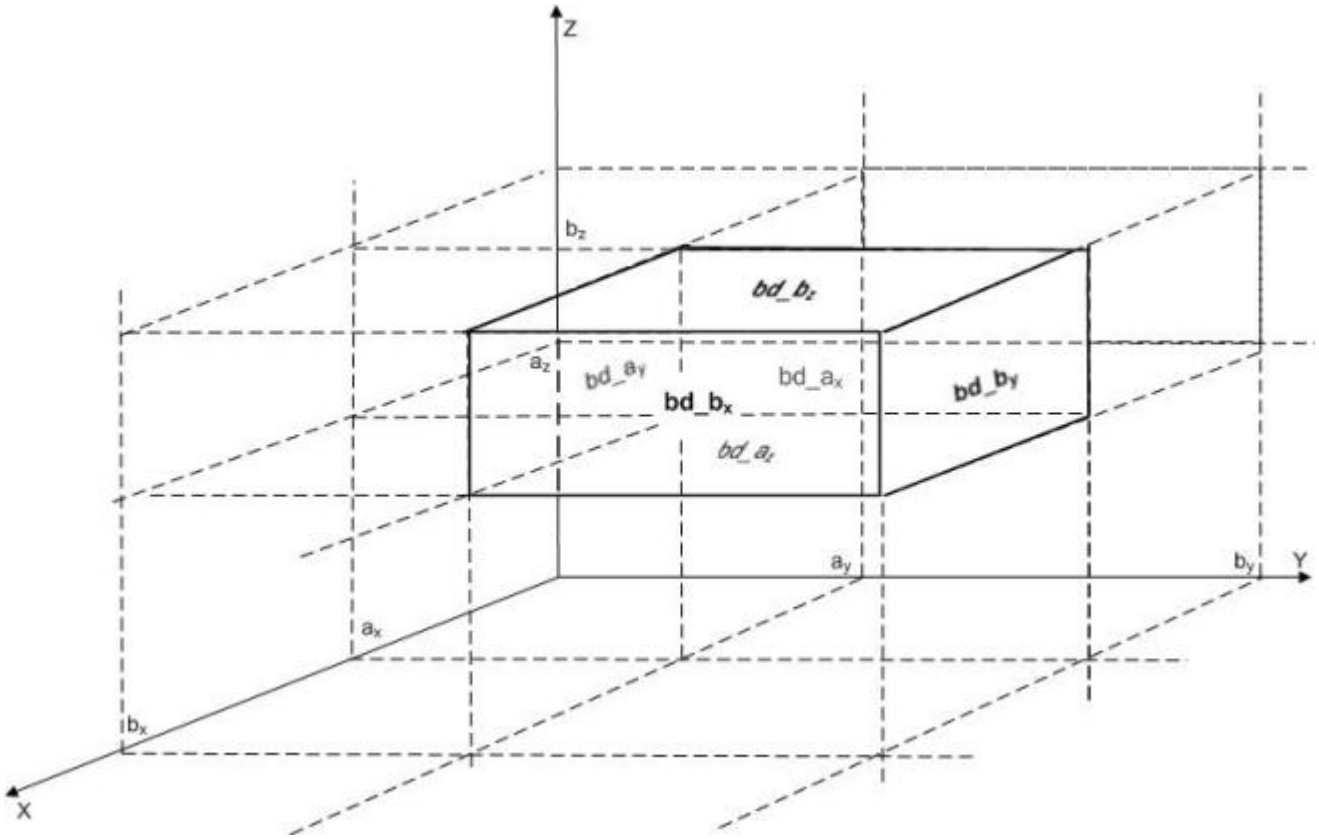
The Poisson Solver interface description uses the following notation for boundaries of a parallelepiped domain $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$:

$bd\_a_x = \{x = a_x, a_y \le y \le b_y, a_z \le z \le b_z\}$, $bd\_b_x = \{x = b_x, a_y \le y \le b_y, a_z \le z \le b_z\}$,

$bd\_a_y = \{a_x \le x \le b_x, y = a_y, a_z \le z \le b_z\}$, $bd\_b_y = \{a_x \le x \le b_x, y = b_y, a_z \le z \le b_z\}$,

$bd\_a_z = \{a_x \le x \le b_x, a_y \le y \le b_y, z = a_z\}$, $bd\_b_x = \{a_x \le x \le b_x, a_y \le y \le b_y, z = b_z\}$.

The following figure shows these boundaries:



The wildcard "+" may stand for any of the symbols a_x, b_x, a_y, b_y, a_z, b_z, so *bd_+* denotes any of the above boundaries.

Three-dimensional (3D) Helmholtz problem

The 3D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} + qu = f(x,y,z),\ q = const \geq 0$$

in a parallelepiped, that is, a parallelepiped domain $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$, with one of the following boundary conditions on each boundary *bd_+*:

- The Dirichlet boundary condition

  $u(x,y,z) = G(x,y,z)$
- The Neumann boundary condition

  $\frac{\partial u}{\partial n}(x,y,z) = g(x,y,z)$

  where

  $n = -x$ on bd_a_x, $n = x$ on bd_b_x,

  $n = -y$ on bd_a_y, $n = y$ on bd_b_y,

  $n = -z$ on bd_a_z, $n = z$ on bd_b_z.
- Periodic boundary conditions

  $u(a_x,y,z) = u(b_x,y,z),\ \frac{\partial}{\partial x}u(a_x,y,z) = \frac{\partial}{\partial x}u(b_x,y,z),$

  $u(x,a_y,z) = u(x,\ b_y,z),\ \frac{\partial}{\partial y}u(x,a_y,z) = \frac{\partial}{\partial y}u(x,b_y,z),$

$$u(x, y, a_z) = u(x, y, b_z), \frac{\partial}{\partial z}u(x, y, a_z) = \frac{\partial}{\partial z}u(x, y, b_z).$$

Three-dimensional (3D) Poisson problem

The Poisson problem is a special case of the Helmholtz problem, when *q*=0. The 3D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} = f(x, y, z)$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with the Dirichlet, Neumann, or periodic boundary conditions on each boundary *bd_*+.

Three-dimensional (3D) Laplace problem

The Laplace problem is a special case of the Helmholtz problem, when *q*=0 and *f(x, y, z)*=0. The 3D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with the Dirichlet, Neumann, or periodic boundary conditions on each boundary *bd_*+.

Approximation of 3D problems

To find an approximate solution for each of the 3D problems, a uniform mesh can be defined in the parallelepiped domain as:

$$\left\{x_i = a_x + ih_x, y_j = a_y + jh_y, z_k = a_z + jh_z\right\},$$

where

$$i = 0, ..., n_x, \; j = 0, ..., n_y, \; k = 0, ..., n_z,$$

$$h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}, h_z = \frac{b_z - a_z}{n_z}.$$

The Poisson Solver uses the standard seven-point finite difference approximation on this mesh to compute the approximation to the solution. The values of the approximate solution will be computed in the mesh points (x_i, y_j, z_k), provided that you can supply the values of the right-hand side *f(x, y, z)* in these points and the values of the appropriate boundary functions *G(x, y, z)* and/or *g(x, y, z)* in the mesh points laying on the boundary of the parallelepiped domain.

Sequence of Invoking Poisson Solver Routines

NOTE
This description always shows the solution process for the Helmholtz problem, because Fast Poisson Solvers and Fast Laplace Solvers are special cases of Fast Helmholtz Solvers (see Poisson Solver Implementation).

The Poisson Solver interface enables you to compute a solution of the Helmholtz problem in four steps. Each step is performed by a dedicated routine. Table "Poisson Solver Interface Routines" lists the routines and briefly describes their purpose.

Most Poisson Solver routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names. The routines for the Cartesian coordinate system have 2D and 3D versions. Their names end respectively in "2D" and "3D". The routines for spherical coordinate system have periodic and non-periodic versions. Their names end respectively in "p" and "np".

Poisson Solver Interface Routines

Routine	Description
?_init_Helmholtz_2D/?_init_Helmholtz_3D/ ?_init_sph_p/?_init_sph_np	Initializes basic data structures for Fast Helmholtz Solver in the 2D/3D/periodic/ non-periodic case, respectively.
?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/ ?_commit_sph_p/?_commit_sph_np	Checks consistency and correctness of input data and initializes data structures for the solver, including those used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface[1].
?_Helmholtz_2D/?_Helmholtz_3D/?_sph_p/?_sph_np	Computes an approximate solution of the 2D/3D/periodic/non-periodic Helmholtz problem (see Poisson Solver Implementation) specified by the parameters.
free_Helmholtz_2D/free_Helmholtz_3D/ free_sph_p/free_sph_np	Releases the memory used by the data structures needed for calling the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface[1].

[1]Poisson Solver routines call the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface for better performance.

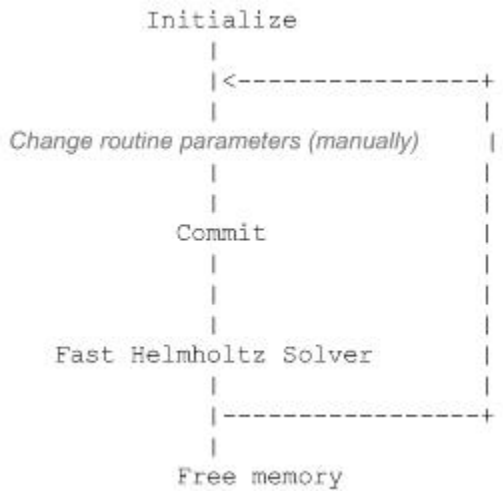
To find an approximate solution of Helmholtz problem only once, the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver interface routines are normally invoked in the order in which they are listed inTable "Poisson Solver Interface Routines".

NOTE
Though the order of invoking Poisson Solver routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in Figure "Typical Order of Invoking Poisson Solver Routines" indicates the typical order in which Poisson Solver routines can be invoked in a general case.

__border__top

Typical Order of Invoking Poisson Solver Routines



A general scheme of using Poisson Solver routines for double-precision computations in a 3D Cartesian case is shown below. You can change this scheme to a scheme for single-precision computations by changing the initial letter of the Poisson Solver routine names from "d" to "s". You can also change the scheme below from the 3D to 2D case by changing the ending of the Poisson Solver routine names.

```
...
d_init_Helmholtz_3D(&ax, &bx, &ay, &by, &az, &bz, &nx, &ny, &nz, BCtype, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f. If you want to keep the data
that is stored in f, save it to another location before the function call below */
d_commit_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar,
dpar, &stat);
d_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar,
&stat);
free_Helmholtz_3D (&xhandle, &yhandle, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

A general scheme of using Poisson Solver routines for double-precision computations in a spherical periodic case is shown below. You can change this scheme to a scheme for single-precision computations by changing the initial letter of the Poisson Solver routine names from "d" to "s". You can also change the scheme below to a scheme for a non-periodic case by changing the ending of the Poisson Solver routine names from "p" to "np".

```
...
d_init_sph_p(&ap,&bp,&at,&bt,&np,&nt,&q,ipar,dpar,&stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f. If you want to keep the data
that is stored in f, save it to another location before the function call below */
d_commit_sph_p(f,&handle_s,&handle_c,ipar,dpar,&stat);
d_sph_p(f,&handle_s,&handle_c,ipar,dpar,&stat);
free_sph_p(&handle_s,&handle_c,ipar,&stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

You can find examples of code that uses Poisson Solver routines to solve Helmholtz problem (in both Cartesian and spherical cases) in the `examples\pdepoissonf\source` folderin your Intel® oneAPI Math Kernel Library (oneMKL) directory.

Fast Poisson Solver Interface Description

All numerical types in this section are either standard C types `float` and `double` or `MKL_INT` integer type. Fortran users can call the routines with `REAL` and `DOUBLE PRECISION` types of floating-point values and either `INTEGER` or `INTEGER*8` integer type depending on the programming interface (LP64 or ILP64). To better understand usage of the types, see examples in the `examples\pdepoissonf\source` folderin your Intel® oneAPI Math Kernel Library (oneMKL) directory.

Routine Options

All Poisson Solver routines use parameters for passing various options to the routines. These parameters are arrays *ipar*, *dpar*, and *spar*. Values for these parameters should be specified very carefully (see Common Parameters). You can change these values during computations to meet your needs. For more details, see the descriptions of specific routines.

WARNING
To avoid failure or incorrect results, you must provide correct and consistent parameters to the routines.

User Data Arrays

Poisson Solver routines take arrays of user data as input. For example, the `d_Helmholtz_3D`routine takes user arrays to compute an approximate solution to the 3D Helmholtz problem. To minimize storage requirements and improve the overall run-time efficiency, Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver routines do not make copies of user input arrays.

NOTE
If you need a copy of your input data arrays, you must save them yourself.

For better performance, align your data arrays as recommended in the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* (search the document for coding techniques to improve performance).

Routines for the Cartesian Solver

The section describes Poisson Solver routines for the Cartesian case, their syntax, parameters, and return values. All flavors of the same routine are described together: single- and double-precision and 2D and 3D.

NOTE
Some of the routine parameters are used only in the 3D Fast Helmholtz Solver.

Poisson Solver routines call Intel® oneAPI Math Kernel Library (oneMKL) FFT routines (described inFFT Functions), which enhance performance of the Poisson Solver routines.

?_init_Helmholtz_2D/?_init_Helmholtz_3D

Initializes basic data structures of the Fast 2D/3D Helmholtz Solver.

Syntax

```
void d_init_Helmholtz_2D (const double * ax, const double * bx, const double * ay,
const double * by, const MKL_INT * nx, const MKL_INT * ny, const char * BCtype, const
double * q, MKL_INT * ipar, double * dpar, MKL_INT * stat);

void s_init_Helmholtz_2D (const float * ax, const float * bx, const float * ay, const
float * by, const MKL_INT * nx, const MKL_INT * ny, const char * BCtype, const float *
q, MKL_INT * ipar, float * spar, MKL_INT * stat);

void d_init_Helmholtz_3D (const double * ax, const double * bx, const double * ay,
const double * by, const double * az, const double * bz, const MKL_INT * nx, const
MKL_INT * ny, const MKL_INT * nz, const char * BCtype, const double * q, MKL_INT *ipar,
double * dpar, MKL_INT * stat);

void s_init_Helmholtz_3D (const float * ax, const float * bx, const float * ay, const
float * by, const float * az, const float * bz, const MKL_INT * nx, const MKL_INT * ny,
const MKL_INT * nz, const char * BCtype, const float * q, MKL_INT * ipar, float * spar,
MKL_INT * stat);
```

Include Files

- `mkl_poisson.f90`

Input Parameters

ax `double*` for `d_init_Helmholtz_2D/d_init_Helmholtz_3D`,

`float*` for `s_init_Helmholtz_2D/s_init_Helmholtz_3D`.

The coordinate of the leftmost boundary of the domain along the x-axis.

bx

`double*` for `d_init_Helmholtz_2D/d_init_Helmholtz_3D`,

`float*` for `s_init_Helmholtz_2D/s_init_Helmholtz_3D`.

The coordinate of the rightmost boundary of the domain along the x-axis.

ay

`double*` for `d_init_Helmholtz_2D/d_init_Helmholtz_3D`,

`float*` for `s_init_Helmholtz_2D/s_init_Helmholtz_3D`.

The coordinate of the leftmost boundary of the domain along the y-axis.

by

`double*` for `d_init_Helmholtz_2D/d_init_Helmholtz_3D`,

`float*` for `s_init_Helmholtz_2D/s_init_Helmholtz_3D`.

The coordinate of the rightmost boundary of the domain along the y-axis.

az

`double*` for `d_init_Helmholtz_3D`,

`float*` for `s_init_Helmholtz_3D`.

The coordinate of the leftmost boundary of the domain along the z-axis. This parameter is needed only for the `?_init_Helmholtz_3D` routine.

bz

`double*` for `d_init_Helmholtz_3D`,

`float*` for `s_init_Helmholtz_3D`.

The coordinate of the rightmost boundary of the domain along the z-axis. This parameter is needed only for the `?_init_Helmholtz_3D` routine.

nx

`MKL_INT*`. The number of mesh intervals along the x-axis.

ny

`MKL_INT*`. The number of mesh intervals along the y-axis.

nz

`MKL_INT*`. The number of mesh intervals along the z-axis. This parameter is needed only for the `?_init_Helmholtz_3D` routine.

BCtype

`char*`. Contains the type of boundary conditions on each boundary. Must contain four characters for `?_init_Helmholtz_2D` and six characters for `?_init_Helmholtz_3D`. Each of the characters can be 'N' (Neumann boundary condition), 'D' (Dirichlet boundary condition), or 'P' (periodic boundary conditions). Specify the types of boundary conditions for the boundaries in the following order: *bd_a*$_x$, *bd_b*$_x$, *bd_a*$_y$, *bd_b*$_y$, *bd_a*$_z$, and *bd_b*$_z$. Specify periodic boundary conditions on the respective boundaries in pairs (for example, 'PPDD' or 'NNPP' in the 2D case). The types of boundary conditions for the last two boundaries are needed only in the 3D case.

q

`double*` for `d_init_Helmholtz_2D/d_init_Helmholtz_3D`,

`float*` for `s_init_Helmholtz_2D/s_init_Helmholtz_3D` .

	The constant Helmholtz coefficient. Note that to solve Poisson or Laplace problem, you should set the value of *q* to 0.

Output Parameters

ipar	MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to ipar).
dpar	double array of size 5*nx/2+7 in the 2D case or 5*(nx+ny)/2+9 in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to dpar and spar).
spar	float array of size 5*nx/2+7 in the 2D case or 5*(nx+ny)/2+9 in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to dpar and spar).
stat	MKL_INT*. Routine completion status, which is also written to *ipar[0]*. Continue to call other Poisson Solver routines only if the status is 0.

Description

The ?_init_Helmholtz_2D/?_init_Helmholtz_3D routines initialize basic data structures for Poisson Solver computations of the appropriate precision. All routines invoked after a call to a ?_init_Helmholtz_2D/?_init_Helmholtz_3D routine use values of the *ipar*, *dpar* and *spar* array parameters returned by the routine. Detailed description of the array parameters can be found in Common Parameters.

Caution
Data structures initialized and created by 2D flavors of the routine cannot be used by 3D flavors of any Poisson Solver routines, and vice versa.

You can skip calls to these routines in your code. However, see Caveat on Parameter Modifications for information on initializing the data structures.

Return Values

stat= 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this *stat* value.
stat= -99999	The routine failed to complete the task because of a fatal error.

_commit_Helmholtz_2D/?_commit_Helmholtz_3D

Checks consistency and correctness of input data and initializes certain data structures required to solve 2D/3D Helmholtz problem.

Syntax

```
void d_commit_Helmholtz_2D (double * f, const double * bd_ax, const double * bd_bx,
const double * bd_ay, const double * bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT *
ipar, double * dpar, MKL_INT * stat );
```

```
void s_commit_Helmholtz_2D (float * f, const float * bd_ax, const float * bd_bx, const float * bd_ay, const float * bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT * ipar, float * spar, MKL_INT * stat );
```

```
void d_commit_Helmholtz_3D (double * f, const double * bd_ax, const double * bd_bx, const double * bd_ay, const double * bd_by, const double * bd_az, const double * bd_bz, DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar, double * dpar, MKL_INT * stat );
```

```
void s_commit_Helmholtz_3D (float * f, const float * bd_ax, const float * bd_bx, const float * bd_ay, const float * bd_by, const float * bd_az, const float * bd_bz, DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar, float * spar, MKL_INT * stat );
```

Include Files

- mkl_poisson.f90

Input Parameters

f

`double*` for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D`,

`float*` for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D`.

Contains the right-hand side of the problem packed in a single vector:

- 2D problem: The size of the vector for the is (*nx*+1)*(*ny*+1). The value of the right-hand side in the mesh point (*i, j*) is stored in *f*[*i* +*j**(*nx*+1)] .
- 3D problem: The size of the vector for the is (*nx*+1)*(*ny*+1)*(*nz* +1). The value of the right-hand side in the mesh point (*i, j, k*) is stored in *f*[*i*+*j**(*nx*+1)+*k**(*nx*+1)*(*ny*+1)].

Note that to solve the Laplace problem, you should set all the elements of the array *f* to 0.

Note also that the array *f* may be altered by the routine. To preserve the *f* vector, save it to another memory location.

ipar

`MKL_INT` array of size 128. Contains integer data to be used by the Fast Helmholtz Solver (for details, refer to `ipar`).

dpar

`double` array of size depending on the dimension of the problem:

- 2D problem: 5**nx*/2+7
- 3D problem: 5*(*nx*+*ny*)/2+9

Contains double-precision data to be used by the Fast Helmholtz Solver (for details, refer to `dpar` and `spar`).

spar

`float` array of size depending on the dimension of the problem:

- 2D problem: 5**nx*/2+7
- 3D problem: 5*(*nx*+*ny*)/2+9

Contains single-precision data to be used by the Fast Helmholtz Solver (for details, refer to `dpar` and `spar`).

bd_ax

`double*` for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D`,

`float*` for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D`.

Contains values of the boundary condition on the leftmost boundary of the domain along the *x*-axis (for more information, refer to a detailed description of *bd_ax*).

bd_bx

`double*` for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D`,

`float*` for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D`.

Contains values of the boundary condition on the rightmost boundary of the domain along the *x*-axis (for more information, refer to a detailed description of *bd_bx*).

bd_ay

`double*` for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D`,

`float*` for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D`.

Contains values of the boundary condition on the leftmost boundary of the domain along the *y*-axis (for more information, refer to a detailed description of *bd_ay*).

bd_by

`double*` for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D`,

`float*` for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D`.

Contains values of the boundary condition on the rightmost boundary of the domain along the *y*-axis (for more information, refer to a detailed description of *bd_by*).

bd_az

`double*` for `d_commit_Helmholtz_3D`,

`float*` for `s_commit_Helmholtz_3D`.

Used only by `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the leftmost boundary of the domain along the *z*-axis (for more information, refer to a detailed description of *bd_az*).

bd_bz

`double*` for `d_commit_Helmholtz_3D`,

`float*` for `s_commit_Helmholtz_3D`.

Used only by `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along the *z*-axis (for more information, refer to a detailed description of *bd_bz*).

Output Parameters

f

Contains right-hand side of the problem, possibly altered on output.

ipar

Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in `ipar`.

dpar

Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in `dpar` and `spar`.

spar

Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in `dpar` and `spar`.

xhandle, yhandle

`DFTI_DESCRIPTOR_HANDLE*`. Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer toFFT Functions). *yhandle* is used only by `?_commit_Helmholtz_3D`.

stat	MKL_INT*. Routine completion status, which is also written to *ipar[0]*. Continue to call other Poisson Solver routines only if the status is 0.

Description

The ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routines check the consistency and correctness of the parameters to be passed to the solver routines ?_Helmholtz_2D/?_Helmholtz_3D. They also initialize the *xhandle* and *yhandle* data structures, *ipar* array, and *dpar* or *spar* array, depending upon the routine precision. Refer to Common Parameters to find out which particular array elements the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routines initialize and to what values these elements are initialized.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of Poisson Solver routines, see Caveat on Parameter Modifications.
Unlike ?_init_Helmholtz_2D/?_init_Helmholtz_3D, you must call the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routines in your code. Values of *ax*, *bx*, *ay*, *by*, *az*, and *bz* are passed to the routines with the *spar/dpar* array, and values of *nx*, *ny*, *nz*, and *BCtype* are passed with the *ipar* array.

Return Values

stat= 1	The routine completed without errors but with warnings.
stat= 0	The routine successfully completed the task.
stat= -100	The routine stopped because an error in the input data was found, or the data in the *dpar*, *spar*, or *ipar* array was altered by mistake.
stat= -1000	The routine stopped because of an Intel® oneAPI Math Kernel Library (oneMKL) FFT or TT interface error.
stat= -10000	The routine stopped because the initialization failed to complete or the parameter *ipar*[0] was altered by mistake.
stat= -99999	The routine failed to complete the task because of a fatal error.

?_Helmholtz_2D/?_Helmholtz_3D

Computes the solution of the 2D/3D Helmholtz problem specified by the parameters.

Syntax

```
void d_Helmholtz_2D (double * f, const double * bd_ax, const double * bd_bx, const double * bd_ay, const double *bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT * ipar, const double * dpar, MKL_INT * stat );
```

```
void s_Helmholtz_2D (float * f, const float * bd_ax, const float * bd_bx, const float * bd_ay, const float * bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT * ipar, const float * spar, MKL_INT * stat );
```

```
void d_Helmholtz_3D (double * f, const double * bd_ax, const double * bd_bx, const double * bd_ay, const double *bd_by, const double * bd_az, const double * bd_bz, DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar, const double * dpar, MKL_INT * stat );
```

```
void s_Helmholtz_3D (float * f, const float * bd_ax, const float * bd_bx, const float *
bd_ay, const float * bd_by, const float * bd_az, const float * bd_bz,
DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar,
const float * spar, MKL_INT * stat );
```

Include Files

- mkl_poisson.f90

Input Parameters

f

double* for d_Helmholtz_2D/d_Helmholtz_3D,

float* for s_Helmholtz_2D/s_Helmholtz_3D.

Contains the right-hand side of the problem packed in a single vector and modified by the appropriate ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routine. Note that an attempt to substitute the original right-hand side vector, which was passed to the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routine, at this point results in an incorrect solution.

- 2D problem: the size of the vector is (*nx*+1)*(*ny*+1). The value of the modified right-hand side in the mesh point (*i, j*) is stored in *f*[*i* +*j**(*nx*+1)].
- 3D problem: the size of the vector is (*nx*+1)*(*ny*+1)*(*nz*+1). The value of the modified right-hand side in the mesh point (*i, j, k*) is stored in *f*[*i*+*j**(*nx*+1)+*k**(*nx*+1)*(*ny*+1)].

xhandle, yhandle

DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer toFFT Functions). *yhandle* is used only by ?_Helmholtz_3D.

ipar

MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to ipar).

dpar

double array of size depending on the dimension of the problem:

- 2D problem: 5**nx*/2+7
- 3D problem: 5*(*nx*+*ny*)/2+9

Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to dpar and spar).

spar

float array of size depending on the dimension of the problem:

- 2D problem: 5**nx*/2+7
- 3D problem: 5*(*nx*+*ny*)/2+9

Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to dpar and spar).

bd_ax

double* for d_Helmholtz_2D/d_Helmholtz_3D,

float* for s_Helmholtz_2D/s_Helmholtz_3D.

Contains values of the boundary condition on the leftmost boundary of the domain along the *x*-axis (for more information, refer to a detailed description of *bd_ax*).

bd_bx
: `double*` for `d_Helmholtz_2D/d_Helmholtz_3D`,
`float*` for `s_Helmholtz_2D/s_Helmholtz_3D`.
Contains values of the boundary condition on the rightmost boundary of the domain along the *x*-axis (for more information, refer to a detailed description of *bd_bx*).

bd_ay
: `double*` for `d_Helmholtz_2D/d_Helmholtz_3D`,
`float*` for `s_Helmholtz_2D/s_Helmholtz_3D`.
Contains values of the boundary condition on the leftmost boundary of the domain along the *y*-axis for more information, refer to a detailed description of *bd_ay*).

bd_by
: `double*` for `d_Helmholtz_2D/d_Helmholtz_3D`,
`float*` for `s_Helmholtz_2D/s_Helmholtz_3D`.
Contains values of the boundary condition on the rightmost boundary of the domain along the *y*-axis (for more information, refer to a detailed description of *bd_by*).

bd_az
: `double*` for `d_Helmholtz_3D`,
`float*` for `s_Helmholtz_3D`.
Used only by `?_Helmholtz_3D`. Contains values of the boundary condition on the leftmost boundary of the domain along the *z*-axis (for more information, refer to a detailed description of *bd_az*).

bd_bz
: `double*` for `d_Helmholtz_3D`,
`float*` for `s_Helmholtz_3D`.
Used only by `?_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along the *z*-axis (for more information, refer to a detailed description of *bd_bz*).

NOTE
To avoid incorrect computation results, do not change arrays *bd_ax*, *bd_bx*, *bd_ay*, *bd_by*, *bd_az*, *bd_bz* between a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine and a subsequent call to the appropriate `?_Helmholtz_2D/?_Helmholtz_3D` routine.

Output Parameters

f
: On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.

xhandle, yhandle
: Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface. Although the addresses do not change, the structures are modified on output.

ipar
: Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in `ipar`.

stat	MKL_INT*. Routine completion status, which is also written to *ipar[0]*. Continue to call other Poisson Solver routines only if the status is 0.

Description

The ?_Helmholtz_2D/?_Helmholtz_3D routines compute the approximate solution of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in Poisson Solver Implementation. The *f* parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of *ax*, *bx*, *ay*, *by*, *az*, and *bz* are passed to the routines with the *spar/dpar* array, and values of *nx*, *ny*, *nz*, and *BCtype* are passed with the *ipar* array.

Return Values

stat= 1	The routine completed without errors but with some warnings.
stat= 0	The routine successfully completed the task.
stat= -2	The routine stopped because division by zero occurred. It usually happens if the data in the *dpar* or *spar* array was altered by mistake.
stat= -3	The routine stopped because the sufficient memory was unavailable for the computations.
stat= -100	The routine stopped because an error in the input data was found or the data in the *dpar*, *spar*, or *ipar* array was altered by mistake.
stat= -1000	The routine stopped because of the Intel® oneAPI Math Kernel Library (oneMKL) FFT or TT interface error.
stat= -10000	The routine stopped because the initialization failed to complete or the parameter *ipar*[0] was altered by mistake.
stat= -99999	The routine failed to complete the task because of a fatal error.

free_Helmholtz_2D/free_Helmholtz_3D

Releases the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_Helmholtz_2D(DFTI_DESCRIPTOR_HANDLE* xhandle, MKL_INT* ipar, MKL_INT* stat);
void free_Helmholtz_3D(DFTI_DESCRIPTOR_HANDLE* xhandle, DFTI_DESCRIPTOR_HANDLE*
yhandle, MKL_INT* ipar, MKL_INT* stat);
```

Include Files

- mkl_poisson.f90

Input Parameters

xhandle, yhandle	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer toFFT Functions). The structure *yhandle* is used only by free_Helmholtz_3D.
ipar	MKL_INT array of size 128. Contains integer data used by Fast Helmholtz Solver (for details, refer to ipar).

Output Parameters

xhandle, yhandle	Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface. Memory allocated for the structures is released on output.
ipar	Contains integer data used by Fast Helmholtz Solver. On output, the status of the routine call is written to *ipar[0]*.
stat	MKL_INT*. Routine completion status, which is also written to *ipar[0]*.

Description

The free_Helmholtz_2D-free_Helmholtz_3D routine releases the memory used by the *xhandle* and *yhandle*structures, which are needed for calling the Intel® oneAPI Math Kernel Library (oneMKL) FFT functions. To release memory allocated for other parameters, include memory release statements in your code.

Return Values

stat= 0	The routine successfully completed the task.
stat= -1000	The routine stopped because of an Intel® oneAPI Math Kernel Library (oneMKL) FFT or TT interface error.
stat= -99999	The routine failed to complete the task because of a fatal error.

Routines for the Spherical Solver

The section describes Poisson Solver routines for the spherical case, their syntax, parameters, and return values. All flavors of the same routine are described together: single- and double-precision and periodic (having names ending in "p") and non-periodic (having names ending in "np").

These Poisson Solver routines also call the Intel® oneAPI Math Kernel Library (oneMKL) FFT routines (described inFFT Functions), which enhance the performance of the Poisson Solver routines.

?_init_sph_p/?_init_sph_np

Initializes basic data structures of the periodic and non-periodic Fast Helmholtz Solver on a sphere.

Syntax

```
void d_init_sph_p (const double * ap, const double * at, const double * bp, const double * bt, const MKL_INT * np, const MKL_INT *nt, const double * q, MKL_INT * ipar, double * dpar, MKL_INT * stat );
```

```
void s_init_sph_p (const float * ap, const float * at, const float * bp, const float *
bt, const MKL_INT * np, const MKL_INT * nt, const float * q, MKL_INT * ipar, float *
spar, MKL_INT * stat );
```

```
void d_init_sph_np (const double * ap, const double * at, const double * bp, const
double * bt, const MKL_INT * np, const MKL_INT *nt, const double * q, MKL_INT * ipar,
double * dpar, MKL_INT * stat );
```

```
void s_init_sph_np (const float * ap, const float * at, const float * bp, const float *
bt, const MKL_INT * np, const MKL_INT * nt, const float * q, MKL_INT * ipar, float *
spar, MKL_INT * stat );
```

Include Files

- mkl_poisson.f90

Input Parameters

ap

`double*` for `d_init_sph_p/d_init_sph_np`,

`float*` for `s_init_sph_p/s_init_sph_np`.

The coordinate (angle) of the leftmost boundary of the domain along the φ-axis.

bp

`double*` for `d_init_sph_p/d_init_sph_np`,

`float*` for `s_init_sph_p/s_init_sph_np`.

The coordinate (angle) of the rightmost boundary of the domain along the φ-axis.

at

`double*` for `d_init_sph_p/d_init_sph_np`,

`float*` for `s_init_sph_p/s_init_sph_np`.

The coordinate (angle) of the leftmost boundary of the domain along the θ-axis.

bt

`double*` for `d_init_sph_p/d_init_sph_np`,

`float*` for `s_init_sph_p/s_init_sph_np`.

The coordinate (angle) of the rightmost boundary of the domain along the θ-axis.

np

`MKL_INT*`. The number of mesh intervals along the φ-axis. Must be even in the periodic case.

nt

`MKL_INT*`. The number of mesh intervals along the θ-axis.

q

`double*` for `d_init_sph_p/d_init_sph_np`,

`float*` for `s_init_sph_p/s_init_sph_np`.

The constant Helmholtz coefficient. To solve the Poisson problem, set the value of *q* to 0.

Output Parameters

ipar

`MKL_INT` array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to `ipar`).

dpar	`double` array of size 5*`np`/2+`nt`+10. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to `dpar` and `spar`).
spar	`float` array of size 5*`np`/2+`nt`+10. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to `dpar` and `spar`).
stat	`MKL_INT*`. Routine completion status, which is also written to *ipar[0]*. Continue to call other Poisson Solver routines only if the status is 0.

Description

The `?_init_sph_p/?_init_sph_np` routines initialize basic data structures for Poisson Solver computations. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the *ipar*, *dpar*, and *spar* array parameters returned by the routine. A detailed description of the array parameters can be found in Common Parameters.

> **Caution**
> Data structures initialized and created by periodic flavors of the routine cannot be used by non-periodic flavors of any Poisson Solver routines for Helmholtz Solver on a sphere, and vice versa.

You can skip calls to these routines in your code. However, see Caveat on Parameter Modifications for information on initializing the data structures.

Return Values

stat= 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this *stat* value.
stat= -99999	The routine failed to complete the task because of fatal error.

?_commit_sph_p/?_commit_sph_np

Checks consistency and correctness of input data and initializes certain data structures required to solve the periodic/non-periodic Helmholtz problem on a sphere.

Syntax

```
void d_commit_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s,
DFTI_DESCRIPTOR_HANDLE* handle_c, MKL_INT* ipar, double* dpar, MKL_INT* stat);
```

```
void s_commit_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE*
handle_c, MKL_INT* ipar, float* spar, MKL_INT* stat);
```

```
void d_commit_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, double*
dpar, MKL_INT* stat);
```

```
void s_commit_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, float*
spar, MKL_INT* stat);
```

Include Files

- mkl_poisson.f90

Input Parameters

f	double* for d_commit_sph_p/d_commit_sph_np, float* for s_commit_sph_p/s_commit_sph_np. Contains the right-hand side of the problem packed in a single vector. The size of the vector is (*np*+1)*(*nt*+1) and value of the right-hand side in the mesh point (*i, j*) is stored in *f*[*i*+*j**(*np*+1)] . Note that the array *f* may be altered by the routine. Save this vector to another memory location if you want to preserve it.
ipar	MKL_INT array of size 128. Contains integer data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to ipar).
dpar	double array of size 5*np/2+nt+10. Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to dpar and spar).
spar	float array of size 5*np/2+nt+10. Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to dpar and spar).

Output Parameters

f	Contains the right-hand side of the problem, possibly altered on output.
ipar	Contains integer data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in ipar.
dpar	Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in dpar and spar.
spar	Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in dpar and spar.
handle_s, handle_c, handle	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer toFFT Functions). *handle_s* and *handle_c* are used only in ?_commit_sph_p and *handle* is used only in ?_commit_sph_np.
stat	MKL_INT*. Routine completion status, which is also written to *ipar[0]*. Continue to call other Poisson Solver routines only if the status is 0.

Description

The ?_commit_sph_p/?_commit_sph_np routines check consistency and correctness of the parameters to be passed to the solver routines ?_sph_p/?_sph_np, respectively. They also initialize certain data structures. The routine ?_commit_sph_p initializes structures *handle_s* and *handle_c*, and ?_commit_sph_np initializes *handle*. The routines also initialize the *ipar* array and *dpar* or *spar* array,

depending upon the routine precision. Refer to Common Parameters to find out which particular array elements the ?_commit_sph_p/?_commit_sph_np routines initialize and to what values these elements are initialized.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of Poisson Solver routines, see Caveat on Parameter Modifications.
Unlike ?_init_sph_p/?_init_sph_np, you must call the ?_commit_sph_p/?_commit_sph_np routines. Values of *np* and *nt* are passed to each of the routines with the *ipar* array.

Return Values

stat= 1	The routine completed without errors but with warnings.
stat= 0	The routine successfully completed the task.
stat= -100	The routine stopped because an error in the input data was found or the data in the *dpar*, *spar*, or *ipar* array was altered by mistake.
stat= -1000	The routine stopped because of an Intel® oneAPI Math Kernel Library (oneMKL) FFT or TT interface error.
stat= -10000	The routine stopped because the initialization failed to complete or the parameter *ipar*[0] was altered by mistake.
stat= -99999	The routine failed to complete the task because of a fatal error.

?_sph_p/?_sph_np

Computes the solution of the spherical Helmholtz problem specified by the parameters.

Syntax

```
void d_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE*
handle_c, MKL_INT* ipar, double* dpar, MKL_INT* stat);
```

```
void s_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE*
handle_c, MKL_INT* ipar, float* spar, MKL_INT* stat);
```

```
void d_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, double* dpar,
MKL_INT* stat);
```

```
void s_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, float* spar,
MKL_INT* stat);
```

Include Files

- mkl_poisson.f90

Input Parameters

f	double* for d_sph_p/d_sph_np, float* for s_sph_p/s_sph_np.

	Contains the right-hand side of the problem packed in a single vector and modified by the appropriate ?_commit_sph_p/?_commit_sph_np routine. Note that an attempt to substitute the original right-hand side vector, which was passed to the ?_commit_sph_p/?_commit_sph_np routine, at this point results in an incorrect solution. The size of the vector is (*np*+1)*(*nt*+1) and the value of the modified right-hand side in the mesh point (*i, j*) is stored in *f*[*i*+*j**(*np*+1)] .
handle_s, handle_c, handle	DFTI_DESCRIPTOR_HANDLE*. Data structures used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer toFFT Functions). *handle_s* and *handle_c* are used only in ?_sph_p and *handle* is used only in ?_sph_np.
ipar	MKL_INT array of size 128. Contains integer data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to ipar).
dpar	double array of size 5*np/2+nt+10. Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to dpar and spar).
spar	float array of size 5*np/2+nt+10. Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to dpar and spar).

Output Parameters

f	On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.
handle_s, handle_c, handle	Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface.
ipar	Contains integer data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in ipar.
dpar	Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in dpar and spar.
spar	Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in dpar and spar.
stat	MKL_INT*. Routine completion status, which is also written to *ipar[0]*. Continue to call other Poisson Solver routines only if the status is 0.

Description

The sph_p/sph_np routines compute the approximate solution on a sphere of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to the formulas given in Poisson Solver Implementation. The *f* parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of *np* and *nt* are passed to each of the routines with the *ipar* array.

Return Values

stat= 1	The routine completed without errors but with warnings.
stat= 0	The routine successfully completed the task.
stat= -2	The routine stopped because division by zero occurred. It usually happens if the data in the *dpar* or *spar* array was altered by mistake.
stat= -3	The routine stopped because the memory was insufficient to complete the computations.
stat= -100	The routine stopped because an error in the input data was found or the data in the *dpar*, *spar*, or *ipar* array was altered by mistake.
stat= -1000	The routine stopped because of an Intel® oneAPI Math Kernel Library (oneMKL) FFT or TT interface error.
stat= -10000	The routine stopped because the initialization failed to complete or the parameter *ipar*[0] was altered by mistake.
stat= -99999	The routine failed to complete the task because of a fatal error.

free_sph_p/free_sph_np

Releases the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_sph_p(DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c,
MKL_INT* ipar, MKL_INT* stat);
void free_sph_np(DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, MKL_INT* stat);
```

Include Files

- mkl_poisson.f90

Input Parameters

handle_s, handle_c, handle	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer toFFT Functions). The structures *handle_s* and *handle_c* are used only in free_sph_p, and *handle* is used only in free_sph_np.
ipar	MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to ipar).

Output Parameters

handle_s, handle_c, handle	Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface. Memory allocated for the structures is released on output.

ipar	Contains integer data to be used by Fast Helmholtz Solver on a sphere. On output, the status of the routine call is written to *ipar[0]*.
stat	MKL_INT*. Routine completion status, which is also written to *ipar[0]*.

Description

The free_sph_p/free_sph_np routine releases the memory used by the *handle_s*, *handle_c* or *handle*structures, needed for calling the Intel® oneAPI Math Kernel Library (oneMKL) FFT functions. To release memory allocated for other parameters, include memory release statements in your code.

Return Values

stat= 0	The routine successfully completed the task.
stat= -1000	The routine stopped because of an Intel® oneAPI Math Kernel Library (oneMKL) FFT or TT interface error.
stat= -99999	The routine failed to complete the task because of a fatal error.

Common Parameters for the Poisson Solver

ipar

ipar	MKL_INT array of size 128, holds integer data needed for Fast Helmholtz Solver (both for Cartesian and spherical coordinate systems). Its elements are described in Table "Elements of the ipar Array":

NOTE
Initial values can be assigned to the array parameters by the appropriate ?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np and ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np routines.

Elements of the ipar Array

Index	Description
1	Contains status value of the last Poisson Solver routine called. In general, it should be 0 on exit from a routine to proceed with the Fast Helmholtz Solver. The element has no predefined values. This element can also be used to inform the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/ ?_commit_sph_p/?_commit_sph_np routines of how the Commit step of the computation should be carried out (see Figure "Typical Order of Invoking Poisson Solver Routines"). A non-zero value of *ipar(1)* with decimal representation $\overline{abc} = 100a + 10b + c$ =100*a*+10*b*+*c*, where each of *a*, *b*, and *c* is equal to 0 or 9, indicates that some parts of the Commit step should be omitted. • If *c*=9, the routine omits checking of parameters and initialization of the data structures. • If *b*=9,

Index	Description
	• In the Cartesian case, the routine omits the adjustment of the right-hand side vector *f* to the Neumann boundary condition (multiplication of boundary values by 0.5 as well as incorporation of the boundary function *g*) and/or the Dirichlet boundary condition (setting boundary values to 0 as well as incorporation of the boundary function *G*). • For the Helmholtz solver on a sphere, the routine omits computation of the spherical weights for the *dpar*/*spar* array. • If *a*=9, the routine omits the normalization of the right-hand side vector *f*. Depending on the solver, the normalization means: • 2D Cartesian case: multiplication by h_y^2, where h_y is the mesh size in the *y* direction (for details, see Poisson Solver Implementation). • 3D (Cartesian) case: multiplication by h_z^2, where h_z is the mesh size in the *z* direction. • Helmholtz solver on a sphere: multiplication by h_θ^2, where h_θ is the mesh size in the θ direction (for details, see Poisson Solver Implementation). Using *ipar(1)* you can adjust the routine to your needs and improve efficiency in solving multiple Helmholtz problems that differ only in the right-hand side. You must be cautious when using this method, because any misunderstanding of the commit process may cause incorrect results or program failure (see also Caveat on Parameter Modifications).
2	Contains error messaging options: • *ipar(2)*=-1 indicates that all error messages are printed to the MKL_Poisson_Library_log.txt file in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device (usually, screen). • *ipar(2)*=0 indicates that no error messages will be printed. • *ipar(2)*=1 is the default value. It indicates that all error messages are printed to the standard output device. In case of errors, the *stat* parameter contains a non-zero value on exit from a routine regardless of the *ipar(2)* setting.
3	Contains warning messaging options: • *ipar(3)*=-1 indicates that all warning messages are printed to the MKL_Poisson_Library_log.txt file in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • *ipar(3)*=0 indicates that no warning messages will be printed. • *ipar(3)*=1 is the default value. It indicates that all warning messages are printed to the standard output device. In case of warnings, the *stat* parameter contains a non-zero value on exit from a routine regardless of the *ipar(3)* setting.
4 through 6	Internal parameters.
Parameters 7 through 12 are used only in the Cartesian case.	
7	Takes this value: • 2, if *BCtype[0]*='P' • 1, if *BCtype[0]*='N' • 0, if *BCtype[0]*='D' • -1, otherwise
8	Takes this value: • 2, if *BCtype[1]*='P'

Index	Description
	• 1, if *BCtype[1]*='N' • 0, if *BCtype[1]*='D' • -1, otherwise
9	Takes this value: • 2, if *BCtype[2]*='P' • 1, if *BCtype[2]*='N' • 0, if *BCtype[2]*='D' • -1, otherwise
10	Takes this value: • 2, if *BCtype[3]*='P' • 1, if *BCtype[3]*='N' • 0, if *BCtype[3]*='D' • -1, otherwise
11	Takes this value: • 2, if *BCtype[4]*='P' • 1, if *BCtype[4]*='N' • 0, if *BCtype[4]*='D' • -1, otherwise
12	Takes this value: • 2, if *BCtype[5]*='P' • 1, if *BCtype[5]*='N' • 0, if *BCtype[5]*='D' • -1, otherwise
13	Takes the value of • *nx*, that is, the number of intervals along the *x*-axis, in the Cartesian case. • *np*, that is, the number of intervals along the φ-axis, in the spherical case.
14	Takes the value of • *ny*, that is, the number of intervals along the *y*-axis, in the Cartesian case • *nt*, that is, the number of intervals along the θ-axis, in the spherical case.
15	Takes the value of *nz*, the number of intervals along the *z*-axis. This parameter is used only in the 3D case (Cartesian).
16 through 23	Internal parameters which define the internal partitioning of the *dpar*/*spar* array.

The values of *ipar(22)* - *ipar(120)* are assigned regardless of the dimension of the problem for the Cartesian solver or of whether the solver on a sphere is periodic.

24	Contains message style options: • *ipar(22)*=0 indicates that Poisson Solver routines prints all error and warning messages in Fortran-style notations.
25	Contains the number of OpenMP threads to be used for computations in a multithreaded environment. The default value is 1 in the serial mode, and the result returned by the mkl_get_max_threads function otherwise.

Index	Description
26 through 29	Internal parameters which define the internal partitioning of the *dpar*/*spar* array.
26	Takes the value of *ipar(19)*+1, which specifies the internal partitioning of the *dpar/spar* array in the periodic Cartesian case.
27	Takes the value of *ipar(24)*+3**ipar(13)*/4, which specifies the internal partitioning of the *dpar/spar* array in the periodic Cartesian case.
28	Takes the value of *ipar(21)*+1, which specifies the internal partitioning of the *dpar/spar* array in the periodic 3D Cartesian case.
29	Takes the value of *ipar(26)*+3**ipar(14)*/4, which specifies the internal partitioning of the *dpar/spar* array in the periodic 3D Cartesian case.
30 through 40	Unused.
41 through 60	Contain the first twenty elements of the *ipar* array of the first Trigonometric Transform that the solver uses. (For details, see Common Parameters in the "Trigonometric Transform Routines" section.)
61 through 80	Contain the first twenty elements of the *ipar* array of the second Trigonometric Transform that the 3D Cartesian and periodic spherical solvers use. (For details, see Common Parameters in the "Trigonometric Transform Routines" section.)
81 through 100	Contain the first twenty elements of the *ipar* array of the third Trigonometric Transform that the solver uses in case of periodic boundary conditions along the *x*-axis. (For details, see Common Parameters in the "Trigonometric Transform Routines" section.)
101 through 120	Contain the first twenty elements of the *ipar* array of the fourth Trigonometric Transform used by periodic spherical solvers and 3D Cartesian solvers with periodic boundary conditions along the *y*-axis. (For details, see Common Parameters in the "Trigonometric Transform Routines" section.)
121 through 129	Internal parameters used by nonuniform 3D solvers.

NOTE
While you can declare the *ipar* array as `MKL_INT ipar(121)`, for future compatibility you should declare *ipar* as `MKL_INT ipar(129)`.

dpar and spar

Arrays *dpar* and *spar* are the same except in the data precision:

dpar Holds data needed for double-precision Fast Helmholtz Solver computations.

- For the Cartesian solver, `double` array of size 5**nx*/2+7 in the 2D case or 5*(*nx*+*ny*)/2+9 in the 3D case; initialized in the `d_init_Helmholtz_2D/d_init_Helmholtz_3D` and `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D` routines.

- For the spherical solver, `double` array of size 5*np/2+nt+10; initialized in the `d_init_sph_p/d_init_sph_np` and `d_commit_sph_p/d_commit_sph_np` routines.

spar

Holds data needed for single-precision Fast Helmholtz Solver computations.

- For the Cartesian solver, `float` array of size 5*nx/2+7 in the 2D case or 5*(nx+ny)/2+9 in the 3D case; initialized in the `s_init_Helmholtz_2D/s_init_Helmholtz_3D` and `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D` routines.
- For the spherical solver, `float` array of size 5*np/2+nt+10; initialized in the `s_init_sph_p/s_init_sph_np` and `s_commit_sph_p/s_commit_sph_np` routines.

Because *dpar* and *spar* have similar elements in each position, the elements are described together in Table "Elements of the `dpar` and `spar` Arrays":

Elements of the dpar and spar Arrays

Index	Description
1	In the Cartesian case, contains the length of the interval along the *x*-axis right after a call to the `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine or the mesh size h_x in the *x* direction (for details, see Poisson Solver Implementation) after a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine. In the spherical case, contains the length of the interval along the φ-axis right after a call to the `?_init_sph_p/?_init_sph_np` routine or the mesh size h_φ in the φ direction (for details, see Poisson Solver Implementation) after a call to the `?_commit_sph_p/?_commit_sph_np` routine.
2	In the Cartesian case, contains the length of the interval along the *y*-axis right after a call to the `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine or the mesh size h_y in the *y* direction (for details, see Poisson Solver Implementation) after a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine. In the spherical case, contains the length of the interval along the θ-axis right after a call to the `?_init_sph_p/?_init_sph_np` routine or the mesh size h_θ in the θ direction (for details, see Poisson Solver Implementation) after a call to the `?_commit_sph_p/?_commit_sph_np` routine.
3	In the Cartesian case, contains the length of the interval along the *z*-axis right after a call to the `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine or the mesh size h_z in the *z* direction (for details, see Poisson Solver Implementation) after a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine. In the Cartesian solver, this parameter is used only in the 3D case. In the spherical solver, contains the coordinate of the leftmost boundary along the θ-axis after a call to the `?_init_sph_p/?_init_sph_np` routine.
4	Contains the value of the coefficient q after a call to the `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` routine.
5	Contains the tolerance parameter after a call to the `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` routine.

Index	Description
	• In the Cartesian case, this value is used only for the pure Neumann boundary conditions (*BCtype*="NNNN" in the 2D case; *BCtype*="NNNNNN" in the 3D case). This is a special case, because the right-hand side of the problem cannot be arbitrary if the coefficient *q* is zero. The Poisson Solver verifies that the classical solution exists (up to rounding errors) using this tolerance. In any case, the Poisson Solver computes the normal solution, that is, the solution that has the minimal Euclidean norm of residual. Nevertheless, the ?_Helmholtz_2D/?_Helmholtz_3D routine informs you that the solution may not exist in a classical sense (up to rounding errors). • In the spherical case, the value is used for the special case of a periodic problem on the entire sphere. This special case is similar to the Cartesian case with pure Neumann boundary conditions. Here the Poisson Solver computes the normal solution as well. The parameter is also used to detect whether the problem is periodic up to rounding errors. The default value for this parameter is 1.0E-10 in case of double-precision computations or 1.0E-4 in case of single-precision computations. You can increase the value of the tolerance, for instance, to avoid the warnings that may appear.
ipar(16) through *ipar(17)*	In the Cartesian case, contain the spectrum of the one-dimensional (1D) problem along the *x*-axis after a call to the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routine. In the spherical case, contains the spectrum of the 1D problem along the φ-axis after a call to the ?_commit_sph_p/?_commit_sph_np routine.
ipar(18) through *ipar(19)*	In the Cartesian case, contain the spectrum of the 1D problem along the *y*-axis after a call to the ?_commit_Helmholtz_3D routine. These elements are used only in the 3D case. In the spherical case, contains the spherical weights after a call to the ?_commit_sph_p/?_commit_sph_np routine.
ipar(20) through *ipar(21)*	Take the values of the (staggered) sine/cosine in the mesh points: • along the *x*-axis after a call to the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routine for a Cartesian solver • along the φ-axis after a call to the ?_commit_sph_p/?_commit_sph_np routine for a spherical solver.
ipar(22) through *ipar(23)*	Take the values of the (staggered) sine/cosine in the mesh points: • along the *y*-axis after a call to the ?_commit_Helmholtz_3D routine for a Cartesian 3D solver • along the φ-axis after a call to the ?_commit_sph_p routine for a spherical periodic solver. These elements are not used in the 2D Cartesian case and in the non-periodic spherical case.
ipar(26) through *ipar(27)*	Take the values of the (staggered) sine/cosine in the mesh points along the *x*-axis after a call to the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routine. These elements are used only in the periodic Cartesian case.
ipar(28) through *ipar(29)-1*	Take the values of the (staggered) sine/cosine in the mesh points along the *x*-axis after a call to the ?_commit_Helmholtz_3D routine. These elements are used only in the periodic 3D Cartesian case.

NOTE
You may define the array size depending upon the type of the problem to solve.

Caveat on Parameter Modifications

Flexibility of the Poisson Solver interface enables you to skip calls to the ?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np routine and to initialize the basic data structures explicitly in your code. You may also need to modify contents of the *ipar*, *dpar*, and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or incorrect results. You can perform a basic check for correctness and consistency of parameters by calling the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routine; however, this does not ensure the correct solution but only reduces the chance of errors or wrong results.

NOTE
To supply correct and consistent parameters to Poisson Solver routines, you should have considerable experience in using the Poisson Solver interface and good understanding of the solution process, as well as elements contained in the *ipar*, *spar*, and *dpar* arrays and dependencies between values of these elements.

In rare occurrences when you fail in tuning parameters for the Fast Helmholtz Solver, refer for technical support at http://www.intel.com/software/products/support/ .

WARNING
The only way that ensures a proper solution of a Helmholtz problem is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar*, and *spar* arrays unless it is necessary.

Parameters That Define Boundary Conditions

Poisson Solver routines for the Cartesian solver use the following common parameters to define the boundary conditions.

Parameters to Define Boundary Conditions for the Cartesian Solver

Parameter	Description

bd_ax	`double*` for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D` and `d_Helmholtz_2D/d_Helmholtz_3D`,
	`float*` for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D` and `s_Helmholtz_2D/s_Helmholtz_3D`.
	Contains values of the boundary condition on the leftmost boundary of the domain along the *x*-axis.
	• 2D problem: the size of the array is *ny*+1. Its contents depend on the boundary conditions as follows:
	  • Dirichlet boundary condition (value of *BCtype*[0] is 'D'): values of the function $G(ax, y_j)$, j=0, ..., *ny*.
	  • Neumann boundary condition (value of *BCtype*[0] is 'N'): values of the function $g(ax, y_j)$, j=0, ..., *ny*.
	  The value corresponding to the index j is placed in *bd_ax*[j].
	• 3D problem: the size of the array is (*ny*+1)*(*nz*+1). Its contents depend on the boundary conditions as follows:

Parameter	Description
	• Dirichlet boundary condition (value of *BCtype*[0] is 'D'): values of the function $G(ax, y_j, z_k)$, j=0, ..., *ny*, k=0, ..., *nz*. • Neumann boundary condition (value of *BCtype*[0] is 'N'): the values of the function $g(ax, y_j, z_k)$, j=0, ..., *ny*, k=0, ..., *nz*. The values are packed in the array so that the value corresponding to indices *(j, k)* is placed in *bd_ax*[$j+k*(ny+1)$].
	For periodic boundary conditions (the value of *BCtype*[0] is 'P'), this parameter is not used, so it can accept a dummy pointer.

bd_bx	`double*` for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D` and `d_Helmholtz_2D/d_Helmholtz_3D`,
	`float*` for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D` and `s_Helmholtz_2D/s_Helmholtz_3D`.
	Contains values of the boundary condition on the rightmost boundary of the domain along the *x*-axis.
	• 2D problem: the size of the array is *ny*+1. Its contents depend on the boundary conditions as follows:
	  • Dirichlet boundary condition (value of *BCtype*[1] is 'D'): values of the function $G(bx, y_j)$, j=0, ..., *ny*.
	  • Neumann boundary condition (value of *BCtype*[1] is 'N'): values of the function $g(bx, y_j)$, j=0, ..., *ny*.
	  The value corresponding to the index j is placed in *bd_bx*[j].
	• 3D problem: the size of the array is (*ny*+1)*(*nz*+1). Its contents depend on the boundary conditions as follows:
	  • Dirichlet boundary condition (value of *BCtype*[1] is 'D'): values of the function $G(bx, y_j, z_k)$, j=0, ..., *ny*, k=0, ..., *nz*.
	  • Neumann boundary condition (value of *BCtype*[1] is 'N'): values of the function $g(bx, y_j, z_k)$, j=0, ..., *ny*, k=0, ..., *nz*.
	  The values are packed in the array so that the value corresponding to indices *(j, k)* is placed in *bd_bx*[$j+k*(ny+1)$].
	For periodic boundary conditions (the value of *BCtype*[1] is 'P'), this parameter is not used, so it can accept a dummy pointer.

bd_ay	`double*` for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D` and `d_Helmholtz_2D/d_Helmholtz_3D`,
	`float*` for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D` and `s_Helmholtz_2D/s_Helmholtz_3D`.
	Contains values of the boundary condition on the leftmost boundary of the domain along the *y*-axis.
	• 2D problem: the size of the array is *nx*+1. Its contents depend on the boundary conditions as follows:
	  • Dirichlet boundary condition (value of *BCtype*[2] is 'D'): values of the function $G(x_i, ay)$, i=0, ..., *nx*.
	  • Neumann boundary condition (value of *BCtype*[2] is 'N'): values of the function $g(x_i, ay)$, i=0, ..., *nx*.
	  The value corresponding to the index i is placed in *bd_ay*[i].
	• 3D problem: the size of the array is (*nx*+1)*(*nz*+1). Its contents depend on the boundary conditions as follows:

Parameter	Description
	• Dirichlet boundary condition (value of *BCtype*[2] is 'D'): values of the function $G(x_i, ay, z_k)$, i=0, ..., *nx*, k=0, ..., *nz*. • Neumann boundary condition (value of *BCtype*[2] is 'N'): values of the function $g(x_i, ay, z_k)$, i=0, ..., *nx*, k=0, ..., *nz*. The values are packed in the array so that the value corresponding to indices *(i, k)* is placed in *bd_ay*[*i*+*k**(*nx*+1)]. For periodic boundary conditions (the value of *BCtype*[2] is 'P'), this parameter is not used, so it can accept a dummy pointer.

bd_by	`double*` for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D` and `d_Helmholtz_2D/d_Helmholtz_3D`,
	`float*` for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D` and `s_Helmholtz_2D/s_Helmholtz_3D`.
	Contains values of the boundary condition on the rightmost boundary of the domain along the *y*-axis.
	• 2D problem: the size of the array is *nx*+1. Its contents depend on the boundary conditions as follows:
	  • Dirichlet boundary condition (value of *BCtype*[3] is 'D'): values of the function $G(x_i, by)$, i=0, ..., *nx*.
	  • Neumann boundary condition (value of *BCtype*[3] is 'N'): values of the function $g(x_i, by)$, i=0, ..., *nx*.
	  The value corresponding to the index *i* is placed in *bd_by*[*i*].
	• 3D problem: the size of the array is (*nx*+1)*(*nz*+1). Its contents depend on the boundary conditions as follows:
	  • Dirichlet boundary condition (value of *BCtype*[3] is 'D'): values of the function $G(x_i, by, z_k)$, i=0, ..., *nx*, k=0, ..., *nz*.
	  • Neumann boundary condition (value of *BCtype*[3] is 'N'): values of the function $g(x_i, by, z_k)$, i=0, ..., *nx*, k=0, ..., *nz*.
	  The values are packed in the array so that the value corresponding to indices *(i, k)* is placed in *bd_by*[*i*+*k**(*nx*+1)].
	For periodic boundary conditions (the value of *BCtype*[3] is 'P'), this parameter is not used, so it can accept a dummy pointer.

bd_az	`double*` for `d_commit_Helmholtz_3D` and `d_Helmholtz_3D`, `float*` for `s_commit_Helmholtz_3D` and `s_Helmholtz_3D`. Used only by `?_commit_Helmholtz_3D` and `?_Helmholtz_3D`. Contains values of the boundary condition on the leftmost boundary of the domain along the *z*-axis. The size of the array is (*nx*+1)*(*ny*+1). Its contents depend on the boundary conditions as follows: • Dirichlet boundary condition (value of *BCtype*[4] is 'D'): values of the function $G(x_i, y_j, az)$, i=0, ..., *nx*, j=0, ..., *ny*. • Neumann boundary condition (value of *BCtype*[4] is 'N'), values of the function $g(x_i, y_j, az)$, i=0, ..., *nx*, j=0, ..., *ny*. The values are packed in the array so that the value corresponding to indices *(i, j)* is placed in *bd_az*[*i*+*j**(*nx*+1)]. For periodic boundary conditions (the value of *BCtype*[4] is 'P'), this parameter is not used, so it can accept a dummy pointer.

Parameter	Description
bd_bz	`double*` for `d_commit_Helmholtz_3D` and `d_Helmholtz_3D`, `float*` for `s_commit_Helmholtz_3D` and `s_Helmholtz_3D`. Used only by `?_commit_Helmholtz_3D` and `?_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along the *z*-axis. The size of the array is (*nx*+1)*(*ny*+1). Its contents depend on the boundary conditions as follows: • Dirichlet boundary condition (value of *BCtype*[5] is 'D'): values of the function $G(x_i, y_j, bz)$, i=0, ..., *nx*, j=0, ..., *ny*. • Neumann boundary condition (value of *BCtype*[5] is 'N'): values of the function $g(x_i, y_j, bz)$, i=0, ..., *nx*, j=0, ..., *ny*. The values are packed in the array so that the value corresponding to indices *(i, j)* is placed in *bd_bz*[*i*+*j**(*nx*+1)]. For periodic boundary conditions (the value of *BCtype*[5] is 'P'), this parameter is not used, so it can accept a dummy pointer.

Poisson Solver Implementation Details

Several aspects of the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver interface are platform-specific and language-specific. To promote portability of the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver interface across platforms and ease of use across different languages, Intel® oneAPI Math Kernel Library (oneMKL) provides you with the Poisson Solver language-specific header file to include in your code:

- `mkl_poisson.f90`, to be used together with `mkl_dfti.f90`.

NOTE

- Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver interface supports Fortran versions starting with Fortran 90.
- Use of the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver software without including the above language-specific header files is not supported.

Header File

The header file defines the following function prototypes for the Cartesian solver:

```
SUBROUTINE D_INIT_HELMHOLTZ_2D (AX, BX, AY, BY, NX, NY, BCTYPE, Q, IPAR, DPAR, STAT)
   USE MKL_DFTI

Fortran specifics of the Poisson Solver routines usage are similar for all Intel® oneAPI Math Kernel Library (oneMKL) PDE support tools and described inCalling PDE Support Routines from Fortran.

Calling PDE Support Routines from Fortran

The calling interface for all the Intel® oneAPI Math Kernel Library (oneMKL) TT and Poisson Solver routines is designed to be easily used in C. However, you can invoke each TT or Poisson Solver routine directly from Fortran 90 or higher if you are familiar with the inter-language calling conventions of your platform.

The TT or Poisson Solver interface cannot be invoked from FORTRAN 77 due to restrictions imposed by the use of the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface.

The inter-language calling conventions include, but are not limited to, the argument passing mechanisms for the language, the data type mappings from C to Fortran, and how C external names are decorated on the platform.

To promote portability and relieve you of dealing with the calling conventions specifics, the Fortran header file `mkl_trig_transforms.f90` for TT routines and `mkl_poisson.f90` for Poisson Solver routines, used together with `mkl_dfti.f90`, declare a set of macros and introduce type definitions intended to hide the inter-language calling conventions and provide an interface to the routines that looks natural in Fortran.

For example, consider a hypothetical library routine, `foo`, which takes a double-precision vector of length *n*. C users access such a function as follows:

```
MKL_INT n;
  double *x;
  …
  foo(x, &n);
```

As noted above, to invoke `foo`, Fortran users would need to know what Fortran data types correspond to C types `MKL_INT` and `double` (or `float` for single-precision), what argument-passing mechanism the C compiler uses and what, if any, name decoration is performed by the C compiler when generating the external symbol `foo`. However, with the Fortran header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` included, the invocation of `foo` within a Fortran program will look as follows for the LP64 interface (for the ILP64 interface, `INTEGER*8` type will be used instead of `INTEGER*4`):

- For TT interface,

```
use mkl_dfti
use mkl_trig_transforms
INTEGER*4 n
DOUBLE PRECISION, ALLOCATABLE :: x
…
CALL FOO(x,n)
```

- For Poisson Solver interface,

```
use mkl_dfti
use mkl_poisson
INTEGER*4 n
DOUBLE PRECISION, ALLOCATABLE :: x
```

```
…
CALL FOO(x,n)
```

Note that in the above example, the header files `mkl_trig_transforms.f90 / mkl_poisson.f90` and `mkl_dfti.f90` provide a definition for the subroutine `FOO`. To ease the use of Poisson Solver or TT routines in Fortran, the general approach of providing Fortran definitions of names is used throughout the libraries. Specifically, if a name from a Poisson Solver or TT interface is documented as having the C-specific name `foo`, then the Fortran header files provide an appropriate Fortran language type definition `FOO`.

One of the key differences between Fortran and C is the language argument-passing mechanism: C programs use pass-by-value semantics and Fortran programs use pass-by-reference semantics. The Fortran headers ensure proper treatment of this difference. In particular, in the above example, the header files `mkl_trig_transforms.f90 / mkl_poisson.f90` and `mkl_dfti.f90` hide the difference by defining a macro `FOO` that takes the address of the appropriate arguments.

Nonlinear Optimization Problem Solvers

Intel® oneAPI Math Kernel Library (oneMKL) provides tools for solving nonlinear least squares problems using the Trust-Region (TR) algorithms. The general nonlinear solver workflow and naming conventions are described here:

- Nonlinear Solver Organization and Implementation
- Nonlinear Solver Routine Naming Conventions

The solver routines are grouped according to their purpose as follows:

- Nonlinear Least Squares Problem without Constraints
- Nonlinear Least Squares Problem with Linear (Boundary) Constraints
- Jacobian Matrix Calculation Routines

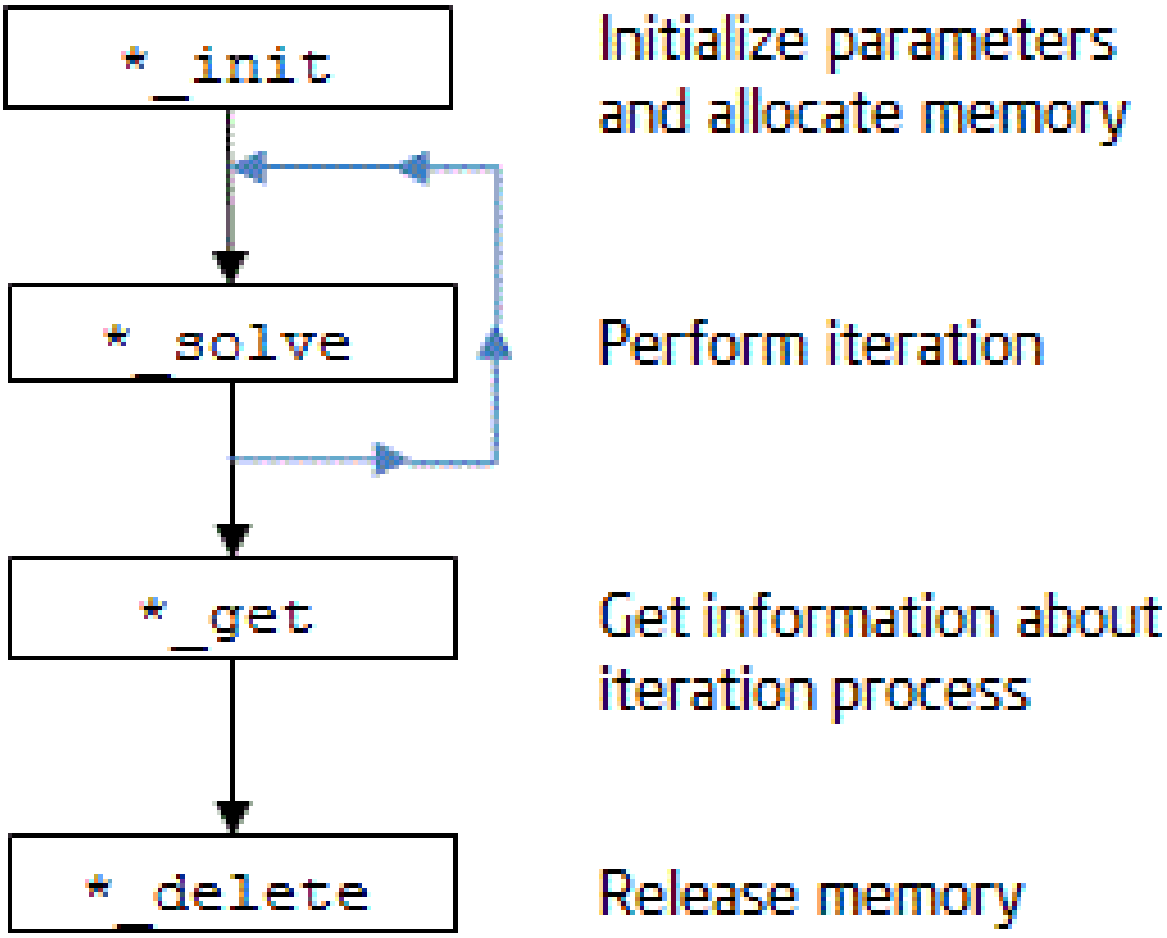
For more information on the key concepts required to understand the use of the Intel® oneAPI Math Kernel Library (oneMKL) nonlinear least squares problem solver routines, see [Conn00].

Nonlinear Solver Organization and Implementation

The Intel® oneAPI Math Kernel Library (oneMKL) solver routines for nonlinear least squares problems use reverse communication interfaces (RCI). That means you need to provide the solver with information required for the iteration process, for example, the corresponding Jacobian matrix, or values of the objective function. RCI removes the dependency of the solver on specific implementation of the operations. However, it does require that you organize a computational loop.

__border__top

Typical order for invoking RCI solver routines



The nonlinear least squares problem solver routines, or Trust-Region (TR) solvers, are implemented with threading support. You can manage the threads using Threading Control Functions. The TR solvers use BLAS and LAPACK routines, and offer the same parallelism as those domains. The `?jacobi` and `?jacobix` routines of Jacobi matrix calculations are parallel. These routines (`?jacobi` and `?jacobix`) make calls to the user-supplied functions with different `x` parameters for multiple threads.

Memory Allocation and Handles

To make the TR solver routines easy to use, you are not required to allocate temporary working storage. The solver allocates all temporary memory internally. To allow multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a data object called a handle. Each TR solver routine creates, uses, or deletes a handle. The handle datatype definition can be found in `mkl_rci.fi` (or `mkl_rci.f90`).

Use one of the mentioned headers (either include it or as a module) and declare the handle as:

```
type(HANDLE_TR) :: handle
```

For a program using compilers that support eight byte integers, declare a handle as:

```
INCLUDE "mkl_rci.fi"
INTEGER*8 handle
```

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Nonlinear Solver Routine Naming Conventions

The TR routine names have the following structure:

```
      <character><name>_<action>( )
```

where

- <*character*> indicates the data type:

`s`	real, single precision
`d`	real, double precision

- <*name*> indicates the task type:

`trnlsp`	nonlinear least squares problem without constraints
`trnlspbc`	nonlinear least squares problem with boundary constraints
`jacobi`	computation of the Jacobian matrix using central differences

- <*action*> indicates an action on the task:

`init`	initializes the solver
`check`	checks correctness of the input parameters
`solve`	solves the problem
`get`	retrieves the number of iterations, the stop criterion, the initial residual, and the final residual
`delete`	releases the allocated data

Nonlinear Least Squares Problem without Constraints

The nonlinear least squares problem without constraints can be described as follows:

$$\min_{x \in R^n} \left\| F(x) \right\|_2^2 = \min_{x \in R^n} \left\| y - f(x) \right\|_2^2, y \in R^m, x \in R^n, f : R^n \to R^m, m \geq n,$$

where

$F(x) : R^n \to R^m$ is a twice differentiable function in R^n.

Solving a nonlinear least squares problem means searching for the best approximation to the vector y with the model function $f_i(x)$ and nonlinear variables x. The best approximation means that the sum of squares of residuals $y_i - f_i(x)$ is the minimum.

See usage examples in the `examples\f\nonlinear_solvers` folderof your Intel® oneAPI Math Kernel Library (oneMKL) directory. Specifically, see `ex_nlsqp_f.f`.

RCI TR Routines

Routine Name	Operation
?trnlsp_init	Initializes the solver.
?trnlsp_check	Checks correctness of the input parameters.
?trnlsp_solve	Solves a nonlinear least squares problem using the Trust-Region algorithm.
?trnlsp_get	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
?trnlsp_delete	Releases allocated data.

?trnlsp_init

Initializes the solver of a nonlinear least squares problem.

Syntax

```
res = strnlsp_init(handle, n, m, x, eps, iter1, iter2, rs)
res = dtrnlsp_init(handle, n, m, x, eps, iter1, iter2, rs)
```

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The ?trnlsp_init routine initializes the solver.

After initialization, all subsequent invocations of the ?trnlsp_solve routine should use the values of the handle returned by ?trnlsp_init. This handle stores internal data, including pointers to the arrays *x* and *eps*. It is important to not move or deallocate these arrays until after calling the ?trnlsp_delete routine.

The *eps* array contains a number indicating the stopping criteria:

eps Value	Description
1	$\Delta < eps(1)$
2	$\|\|F(x)\|\|_2 < eps(2)$
3	The Jacobian matrix is singular. $\|\|J(x)_{(1:m,j)}\|\|_2 < eps(3),\ j = 1, \ldots, n$
4	$\|\|s\|\|_2 < eps(4)$
5	$\|\|F(x)\|\|_2 - \|\|F(x) - J(x)s\|\|_2 < eps(5)$
6	The trial step precision. If $eps(6) = 0$, then the trial step meets the required precision ($\leq 1.0*10^{-10}$).

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.

- `s` is the trial step.

Input Parameters

n	`INTEGER`. Length of *x*.
m	`INTEGER`. Length of *F*(*x*).

x	`REAL` for `strnlsp_init`
	`DOUBLE PRECISION` for `dtrnlsp_init`
	Array of size *n*. Initial guess. A reference to this array is stored in *handle* for later use and modification by `?trnlsp_solve`
	.

eps	`REAL` for `strnlsp_init`
	`DOUBLE PRECISION` for `dtrnlsp_init`
	Array of size 6; contains stopping criteria. See the values in the Description section.
	A reference to this array is stored in *handle* for later use by `?trnlsp_solve`
	.

iter1	`INTEGER`. Specifies the maximum number of iterations.
iter2	`INTEGER`. Specifies the maximum number of iterations of trial step calculation.

rs	`REAL` for `strnlsp_init`
	`DOUBLE PRECISION` for `dtrnlsp_init`
	Definition of initial size of the trust region (boundary of the trial step). The recommend minimum value is 0.1, and the recommended maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. If you set *rs* to 0.0, the solver uses the default value, which is 100.0.

Output Parameters

handle	Type `INTEGER*8`.
res	`INTEGER`. Indicates task completion status. • *res* = `TR_SUCCESS` - the routine completed the task normally. • *res* = `TR_INVALID_OPTION` - there was an error in the input parameters. • *res* = `TR_OUT_OF_MEMORY` - there was a memory error. `TR_SUCCESS`, `TR_INVALID_OPTION`, and `TR_OUT_OF_MEMORY` are defined in the `mkl_rci.fi` include file.

See Also

`?trnlsp_solve`

?trnlsp_check

Checks the correctness of handle and arrays containing Jacobian matrix, objective function, and stopping criteria.

Syntax

`res = strnlsp_check(handle, n, m, fjac, fvec, eps, info)`

`res = dtrnlsp_check(handle, n, m, fjac, fvec, eps, info)`

Include Files

- Fortran: `mkl_rci.fi`, `mkl_rci.f90`

Description

The `?trnlsp_check` routine checks the arrays passed into the solver as input parameters. If an array contains any `INF` or `NaN` values, the routine sets the flag in output array *info*(see the description of the values returned in the Output Parameters section for the `info` array).

Input Parameters

handle	Type `INTEGER*8`.
n	`INTEGER`. Length of *x*.
m	`INTEGER`. Length of *F*(*x*).

fjac	`REAL` for `strnlsp_check`
	`DOUBLE PRECISION` for `dtrnlsp_check`
	Array of size *m* by *n*. Contains the Jacobian matrix of the function.

fvec	`REAL` for `strnlsp_check`
	`DOUBLE PRECISION` for `dtrnlsp_check`
	Array of size *m*. Contains the function values at `X`, where `fvec(i) = (`$y_i - f_i(x)$`)`.

eps	`REAL` for `strnlsp_check`
	`DOUBLE PRECISION` for `dtrnlsp_check`
	Array of size 6; contains stopping criteria. See the values in the Description section of the `?trnlsp_init`.

Output Parameters

info	`INTEGER` Array of size 6. Results of input parameter checking:

Parameter	Used for	Value	Description
info(1)	Flags for *handle*	0	The handle is valid.
		1	The handle is not allocated.
info(2)	Flags for *fjac*	0	The *fjac* array is valid.
		1	The *fjac* array is not allocated
		2	The *fjac* array contains NaN.
		3	The *fjac* array contains Inf.
info(3)	Flags for *fvec*	0	The *fvec* array is valid.
		1	The *fvec* array is not allocated
		2	The *fvec* array contains NaN.
		3	The *fvec* array contains Inf.
info(4)	Flags for *eps*	0	The *eps* array is valid.
		1	The *eps* array is not allocated
		2	The *eps* array contains NaN.
		3	The *eps* array contains Inf.
		4	The *eps* array contains a value less than or equal to zero.

res INTEGER. Information about completion of the task.

res = TR_SUCCESS - the routine completed the task normally.

TR_SUCCESS is defined in the mkl_rci.fi include file.

?trnlsp_solve

Solves a nonlinear least squares problem using the TR algorithm.

Syntax

res = strnlsp_solve(*handle*, *fvec*, *fjac*, *RCI_Request*)

res = dtrnlsp_solve(*handle*, *fvec*, *fjac*, *RCI_Request*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The ?trnlsp_solve routine uses the TR algorithm to solve nonlinear least squares problems.

The problem is stated as follows:

$$\min_{x \in R^n} \left\| F(x) \right\|_2^2 = \min_{x \in R^n} \left\| y - f(x) \right\|_2^2, \; y \in R^m, \; x \in R^n, \; f : R^n \to R^m, \; m \geq n,$$

where

- $F(x) : R^n \to R^m$
- $m \geq n$

From a current point $x_{current}$, the algorithm uses the trust-region approach:

$$\min_{x \in R^n} \left\| F(x_{current}) + J(x_{current})(x_{new} - x_{current}) \right\|_2^2 \quad \text{subject to } \left\| x_{new} - x_{current} \right\| \leq \Delta_{current}$$

to get $x_{new} = x_{current} + s$ that satisfies

$$\min_{x \in R^n} \left\| J^T(x) J(x) s + J^T F(x) \right\|_2^2$$

where

- $J(x)$ is the Jacobian matrix
- s is the trial step
- $||s||_2 \leq \Delta_{current}$
- Δ is the trust-region area.

The *RCI_Request* parameter provides additional information:

RCI_Request **Value**	**Description**
2	Request to calculate the Jacobian matrix and put the result into *fjac*
1	Request to recalculate the function at vector X and put the result into *fvec*
0	One successful iteration step on the current trust-region radius (that does not mean that the value of *x* has changed)
-1	The algorithm has exceeded the maximum number of iterations
-2	$\Delta < eps(1)$
-3	$\|\|F(x)\|\|_2 < eps(2)$
-4	The Jacobian matrix is singular. $\|\|J(x)_{(1:m,j)}\|\|_2 < eps(3), \; j = 1, \ldots, n$
-5	$\|\|s\|\|_2 < eps(4)$
-6	$\|\|F(x)\|\|_2 - \|\|F(x) - J(x)s\|\|_2 < eps(5)$

NOTE
If it is possible to combine computations of the function and the jacobian (`RCI_Request = 1` and `2`), you can do that and provide both updated values for *fvec* and *fjac* as fulfillment of `RCI_Request =1` (and do nothing for `RCI_Request = 2`).

Input Parameters

handle Type `INTEGER*8`.

fvec `REAL` for `strnlsp_solve`

`DOUBLE PRECISION` for `dtrnlsp_solve`

Array of size *m*. Contains the function values at `X`, where *fvec*`(i) = (`y_i – $f_i(x)$`)`.

fjac `REAL` for `strnlsp_solve`

`DOUBLE PRECISION` for `dtrnlsp_solve`

Array of size *m* by *n*. Contains the Jacobian matrix of the function.

Output Parameters

fvec `REAL` for `strnlsp_solve`

`DOUBLE PRECISION` for `dtrnlsp_solve`

Array of size *m*. Updated function evaluated at `x`.

RCI_Request `INTEGER`. Informs about the task stage.

See the Description section for the parameter values and their meaning.

res `INTEGER`. Indicates the task completion.

res = `TR_SUCCESS` - the routine completed the task normally.

`TR_SUCCESS` is defined in the `mkl_rci.fi` include file.

?trnlsp_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

res = `strnlsp_get(`*handle*`, `*iter*`, `*st_cr*`, `*r1*`, `*r2*`)`

res = `dtrnlsp_get(`*handle*`, `*iter*`, `*st_cr*`, `*r1*`, `*r2*`)`

Include Files

- Fortran: `mkl_rci.fi`, `mkl_rci.f90`

Description

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The initial residual is the value of the functional `(||`*y* – *f*`(`*x*`)||)` of the initial *x* values provided by the user.

The final residual is the value of the functional $(||y - f(x)||)$ of the final *x* resulting from the algorithm operation.

The *st_cr* parameter contains a number indicating the stop criterion:

st_cr **Value**	**Description**
1	The algorithm has exceeded the maximum number of iterations
2	$\Delta < eps(1)$
3	$\|\|F(x)\|\|_2 < eps(2)$
4	The Jacobian matrix is singular. $\|\|J(x)_{(1:m,j)}\|\|_2 < eps(3),\ j = 1, \ldots, n$
5	$\|\|s\|\|_2 < eps(4)$
6	$\|\|F(x)\|\|_2 - \|\|F(x) - J(x)s\|\|_2 < eps(5)$

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

handle Type INTEGER*8.

Output Parameters

iter INTEGER. Contains the current number of iterations.

st_cr INTEGER. Contains the stop criterion.

See the Description section for the parameter values and their meanings.

r1 REAL for strnlsp_get

DOUBLE PRECISION for dtrnlsp_get

Contains the residual, $(||y - f(x)||)$ given the initial *x*.

r2 REAL for strnlsp_get

DOUBLE PRECISION for dtrnlsp_get

Contains the final residual, that is, the value of the functional $(||y - f(x)||)$ of the final *x* resulting from the algorithm operation.

res INTEGER. Indicates the task completion.

res = TR_SUCCESS - the routine completed the task normally.

TR_SUCCESS is defined in the mkl_rci.fi include file.

?trnlsp_delete

Releases allocated data.

Syntax

res = strnlsp_delete(*handle*)

res = dtrnlsp_delete(*handle*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The ?trnlsp_delete routine releases all memory allocated for the handle. Only after calling this routine is it safe for the user to move or deallocate the memory referenced by *x* and *eps*.

This routine flags memory as not used, but to actually release all memory you must call the support function mkl_free_buffers.

Input Parameters

handle	Type INTEGER*8.

Output Parameters

res	INTEGER. Indicates the task completion. *res* = TR_SUCCESS means the routine completed the task normally. TR_SUCCESS is defined in the mkl_rci.fi include file.

Nonlinear Least Squares Problem with Linear (Bound) Constraints

The nonlinear least squares problem with linear bound constraints is very similar to the nonlinear least squares problem without constraints but it has the following constraints:

$$l_i \le x_i \le u_i, i = 1, \ldots, n, \quad l, u \in R^n.$$

See usage examples in the examples\f\nonlinear_solvers folderof your Intel® oneAPI Math Kernel Library (oneMKL) directory. Specifically, see ex_nlsqp_bc_f.f .

NOTE There are two options for handling the boundary constraints enabled through the parameter array, see the description of eps(5)

RCI TR Routines for Problem with Bound Constraints

Routine Name	Operation
?trnlspbc_init	Initializes the solver.
?trnlspbc_check	Checks correctness of the input parameters.
?trnlspbc_solve	Solves a nonlinear least squares problem using RCI and the Trust-Region algorithm.
?trnlspbc_get	Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Routine Name	Operation
?trnlspbc_delete	Releases allocated data.

?trnlspbc_init

Initializes the solver of nonlinear least squares problem with linear (boundary) constraints.

Syntax

res = strnlspbc_init(*handle*, *n*, *m*, *x*, *LW*, *UP*, *eps*, *iter1*, *iter2*, *rs*)

res = dtrnlspbc_init(*handle*, *n*, *m*, *x*, *LW*, *UP*, *eps*, *iter1*, *iter2*, *rs*)

Description

The ?trnlspbc_init routine initializes the solver.

After initialization, all subsequent invocations of the ?trnlspbc_solve routine should use the values of the handle returned by ?trnlspbc_init. This handle stores internal data, including pointers to the arrays *x*, *LW*, *UP*, and *eps*. It is important to not move or deallocate these arrays until after calling the ?trnlspbc_delete routine.

The *eps* array contains a number indicating the stopping criteria:

eps Value	Description
1	$\Delta < eps(1)$
2	$\|\|F(x)\|\|_2 < eps(2)$
3	The Jacobian matrix is singular. $\|\|J(x)_{(1:m,j)}\|\|_2 < eps(3),\ j = 1, \ldots, n$
4	$\|\|s\|\|_2 < eps(4)$
5	$\|\|F(x)\|\|_2 - \|\|F(x) - J(x)s\|\|_2 < \|eps(5)\|$ **NOTE** If eps(5) > 0, an extra scaling is applied to 's' after it has been selected, to ensure that it does not leave the specified domain, but scales it down to not cross the boundary. This preserves the solution inside the boundary, but may result in getting stuck in a local minimum on the boundary and exiting early due to this stopping criteria If eps(5) < 0, extra scaling is not applied, which may result in the solution, x, leaving the domain. If this occurs, try starting over with a different initial condition.
6	The trial step precision. If $eps(6) = 0$, then the trial step meets the required precision ($\leq 1.0*10^{-10}$).

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.

- `s` is the trial step.

Input Parameters

n	`INTEGER`. Length of *x*.
m	`INTEGER`. Length of *F*(*x*).

x	`REAL` for `strnlspbc_init`
	`DOUBLE PRECISION` for `dtrnlspbc_init`
	Array of size *n*. Initial guess. A reference to this array is stored in handle for later use and modification by `?trnlspbc_solve`.

LW	`REAL` for `strnlspbc_init`
	`DOUBLE PRECISION` for `dtrnlspbc_init`
	Array of size *n*.
	Contains low bounds for *x* ($lw_i < x_i$). A reference to this array is stored in handle for later use by `?trnlspbc_solve`.

UP	`REAL` for `strnlspbc_init`
	`DOUBLE PRECISION` for `dtrnlspbc_init`
	Array of size *n*.
	Contains upper bounds for *x* ($up_i > x_i$). A reference to this array is stored in handle for later use by `?trnlspbc_solve`.

eps	`REAL` for `strnlspbc_init`
	`DOUBLE PRECISION` for `dtrnlspbc_init`
	Array of size 6; contains stopping criteria. See the values in the Description section. A reference to this array is stored in handle for later use by `?trnlspbc_solve`.

iter1	`INTEGER`. Specifies the maximum number of iterations.
iter2	`INTEGER`. Specifies the maximum number of iterations of trial step calculation.

rs	`REAL` for `strnlspbc_init`
	`DOUBLE PRECISION` for `dtrnlspbc_init`
	Definition of initial size of the trust region (boundary of the trial step). The recommended minimum value is 0.1, and the recommended maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. If you set *rs* to 0.0, the solver uses the default value, which is 100.0.

Output Parameters

handle	Type `INTEGER*8`.
res	`INTEGER`. Informs about the task completion.

- *res* = TR_SUCCESS - the routine completed the task normally.
- *res* = TR_INVALID_OPTION - there was an error in the input parameters.
- *res* = TR_OUT_OF_MEMORY - there was a memory error.

TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in the mkl_rci.fi include file.

?trnlspbc_check

Checks the correctness of handle and arrays containing Jacobian matrix, objective function, lower and upper bounds, and stopping criteria.

Syntax

res = strnlspbc_check(*handle*, *n*, *m*, *fjac*, *fvec*, *LW*, *UP*, *eps*, *info*)

res = dtrnlspbc_check(*handle*, *n*, *m*, *fjac*, *fvec*, *LW*, *UP*, *eps*, *info*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The ?trnlspbc_check routine checks the arrays passed into the solver as input parameters. If an array contains any INF or NaN values, the routine sets the flag in output array *info*(see the description of the values returned in the Output Parameters section for the *info* array).

Input Parameters

handle
Type INTEGER*8.

n
INTEGER. Length of *x*.

m
INTEGER. Length of *F*(*x*).

fjac
REAL for strnlspbc_check
DOUBLE PRECISION for dtrnlspbc_check
Array of size *m* by *n*. Contains the Jacobian matrix of the function.

fvec
REAL for strnlspbc_check
DOUBLE PRECISION for dtrnlspbc_check
Array of size *m*. Contains the function values at X, where *fvec*(*i*) = (y_i – $f_i(x)$).

LW
REAL for strnlspbc_check
DOUBLE PRECISION for dtrnlspbc_check
Array of size *n*.
Contains low bounds for *x* ($lw_i < x_i$).

UP
REAL for strnlspbc_check
DOUBLE PRECISION for dtrnlspbc_check
Array of size *n*.

Contains upper bounds for x ($up_i > x_i$).

eps

`REAL` for `strnlspbc_check`

`DOUBLE PRECISION` for `dtrnlspbc_check`

Array of size 6; contains stopping criteria. See the values in the Description section of the `?trnlspbc_init`.

Output Parameters

info

`INTEGER`

Array of size 6.

Results of input parameter checking:

Parameter	Used for	Value	Description
info(1)	Flags for *handle*	0	The handle is valid.
		1	The handle is not allocated.
info(2)	Flags for *fjac*	0	The *fjac* array is valid.
		1	The *fjac* array is not allocated
		2	The *fjac* array contains `NaN`.
		3	The *fjac* array contains `Inf`.
info(3)	Flags for *fvec*	0	The *fvec* array is valid.
		1	The *fvec* array is not allocated
		2	The *fvec* array contains `NaN`.
		3	The *fvec* array contains `Inf`.
info(4)	Flags for *LW*	0	The *LW* array is valid.
		1	The *LW* array is not allocated
		2	The *LW* array contains `NaN`.
		3	The *LW* array contains `Inf`.
		4	The lower bound is greater than the upper bound.
info(5)	Flags for *up*	0	The *up* array is valid.
		1	The *up* array is not allocated
		2	The *up* array contains `NaN`.
		3	The *up* array contains `Inf`.

Parameter	Used for	Value	Description
		4	The upper bound is less than the lower bound.
info(6)	Flags for *eps*	0	The *eps* array is valid.
		1	The *eps* array is not allocated
		2	The *eps* array contains NaN.
		3	The *eps* array contains Inf.
		4	The *eps* array contains a value less than or equal to zero.

res INTEGER. Information about completion of the task.

res = TR_SUCCESS - the routine completed the task normally.

TR_SUCCESS is defined in the mkl_rci.fi include file.

?trnlspbc_solve

Solves a nonlinear least squares problem with linear (bound) constraints using the Trust-Region algorithm.

Syntax

res = strnlspbc_solve(*handle*, *fvec*, *fjac*, *RCI_Request*)

res = dtrnlspbc_solve(*handle*, *fvec*, *fjac*, *RCI_Request*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The ?trnlspbc_solve routine, based on RCI, uses the Trust-Region algorithm to solve nonlinear least squares problems with linear (bound) constraints. The problem is stated as follows:

$$\min_{x \in R^n} \left\| F(x) \right\|_2^2 = \min_{x \in R^n} \left\| y - f(x) \right\|_2^2, \; y \in R^m, \; x \in R^n, \; f : R^n \to R^m, \; m \geq n$$

where

$l_i \leq x_i \leq u_i$

$i = 1, \ldots, n$.

The *RCI_Request* parameter provides additional information:

RCI_Request Value	Description
2	Request to calculate the Jacobian matrix and put the result into *fjac*
1	Request to recalculate the function at vector X and put the result into *fvec*

RCI_Request Value	Description
0	One successful iteration step on the current trust-region radius (that does not mean that the value of *x* has changed)
-1	The algorithm has exceeded the maximum number of iterations
-2	$\Delta < eps(1)$
-3	$\|\|F(x)\|\|_2 < eps(2)$
-4	The Jacobian matrix is singular. $\|\|J(x)_{(1:m,j)}\|\|_2 < eps(3),\ j = 1, \ldots, n$
-5	$\|\|s\|\|_2 < eps(4)$
-6	$\|\|F(x)\|\|_2 - \|\|F(x) - J(x)s\|\|_2 < \|eps(5)\|$

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- `s` is the trial step.

Input Parameters

handle
Type `INTEGER*8`.

fvec
`REAL` for `strnlspbc_solve`
`DOUBLE PRECISION` for `dtrnlspbc_solve`
Array of size *m*. Contains the function values at `X`, where $fvec(i) = (y_i - f_i(x))$.

fjac
`REAL` for `strnlspbc_solve`
`DOUBLE PRECISION` for `dtrnlspbc_solve`
Array of size *m* by *n*. Contains the Jacobian matrix of the function.

Output Parameters

fvec
`REAL` for `strnlspbc_solve`
`DOUBLE PRECISION` for `dtrnlspbc_solve`
Array of size *m*. Updated function evaluated at `x`.

RCI_Request
`INTEGER`. Informs about the task stage.
See the Description section for the parameter values and their meaning.

res
`INTEGER`. Informs about the task completion.
res = `TR_SUCCESS` means the routine completed the task normally.
`TR_SUCCESS` is defined in the `mkl_rci.fi` include file.

?trnlspbc_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

`res = strnlspbc_get(handle, iter, st_cr, r1, r2)`

`res = dtrnlspbc_get(handle, iter, st_cr, r1, r2)`

Include Files

- Fortran: `mkl_rci.fi`, `mkl_rci.f90`

Description

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The *st_cr* parameter contains a number indicating the stop criterion:

st_cr **Value**	**Description**
1	The algorithm has exceeded the maximum number of iterations
2	$\Delta < eps(1)$
3	$\|\|F(x)\|\|_2 < eps(2)$
4	The Jacobian matrix is singular. $\|\|J(x)_{(1:m,j)}\|\|_2 < eps(3),\ j = 1, \ldots, n$
5	$\|\|s\|\|_2 < eps(4)$
6	$\|\|F(x)\|\|_2 - \|\|F(x) - J(x)s\|\|_2 < eps(5)$

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

handle Type `INTEGER*8`.

Output Parameters

iter `INTEGER`. Contains the current number of iterations.

st_cr `INTEGER`. Contains the stop criterion.

See the Description section for the parameter values and their meanings.

r1 `REAL` for `strnlspbc_get`

`DOUBLE PRECISION` for `dtrnlspbc_get`

Contains the residual, $(||y - f(x)||)$ given the initial x.

r2	REAL for strnlspbc_get DOUBLE PRECISION for dtrnlspbc_get Contains the final residual, that is, the value of the function (||*y* – *f*(*x*)||) of the final *x* resulting from the algorithm operation.
res	INTEGER. Informs about the task completion. *res* = TR_SUCCESS - the routine completed the task normally. TR_SUCCESS is defined in the mkl_rci.fi include file.

?trnlspbc_delete

Releases allocated data.

Syntax

res = strnlspbc_delete(*handle*)

res = dtrnlspbc_delete(*handle*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The ?trnlspbc_delete routine releases all memory allocated for the handle. Only after calling this routine is it safe for the user to move or deallocate the memory referenced by *x, LW, UP,* and *eps.*

> **NOTE**
> This routine flags memory as not used, but to actually release all memory you must call the support function mkl_free_buffers.

Input Parameters

handle	Type INTEGER*8.

Output Parameters

res	INTEGER. Informs about the task completion. *res* = TR_SUCCESS means the routine completed the task normally. TR_SUCCESS is defined in the mkl_rci.fi include file.

Jacobian Matrix Calculation Routines

This section describes routines that compute the Jacobian matrix using the central difference algorithm. Jacobian matrix calculation is required to solve a nonlinear least squares problem and systems of nonlinear equations (with or without linear bound constraints). Routines for calculation of the Jacobian matrix have the "Black-Box" interfaces, where you pass the objective function via parameters. Your objective function must have a fixed interface.

Jacobian Matrix Calculation Routines

Routine Name	Operation
?jacobi_init	Initializes the solver.
?jacobi_solve	Computes the Jacobian matrix of the function on the basis of RCI using the central difference algorithm.
?jacobi_delete	Removes data.
?jacobi	Computes the Jacobian matrix of the fcn function using the central difference algorithm.
?jacobix	Presents an alternative interface for the ?jacobi function enabling you to pass additional data into the objective function.

?jacobi_init

Initializes the solver for Jacobian calculations.

Syntax

res = sjacobi_init(*handle*, *n*, *m*, *x*, *fjac*, *eps*)

res = djacobi_init(*handle*, *n*, *m*, *x*, *fjac*, *eps*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The routine initializes the solver.

Input Parameters

n

INTEGER. Length of *x*.

m

INTEGER. Length of *F*.

x

REAL for sjacobi_init

DOUBLE PRECISION for djacobi_init

Array of size *n*. Vector, at which the function is evaluated.

A reference to this array is stored in *handle* for later use and modification by ?jacobi_solve.

eps

REAL for sjacobi_init

DOUBLE PRECISION for djacobi_init

Precision of the Jacobian matrix calculation.

fjac

REAL for sjacobi_init

DOUBLE PRECISION for djacobi_init

Array of size *m* by *n*. Contains the Jacobian matrix of the function.

A reference to this array is stored in *handle* for later use and modification by ?jacobi_solve.

Output Parameters

handle	Data object of the INTEGER*8. Stores internal data, including pointers to the user-provided arrays *x* and *fjac*. It is important that the user does not move or deallocate these arrays until after calling the ?jacobi_delete routine.
res	INTEGER. Indicates task completion status. • *res* = TR_SUCCESS - the routine completed the task normally. • *res* = TR_INVALID_OPTION - there was an error in the input parameters. • *res* = TR_OUT_OF_MEMORY - there was a memory error. TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in the mkl_rci.fi include file.

?jacobi_solve

Computes the Jacobian matrix of the function using RCI and the central difference algorithm.

Syntax

res = sjacobi_solve(*handle*, *f1*, *f2*, *RCI_Request*)

res = djacobi_solve(*handle*, *f1*, *f2*, *RCI_Request*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The ?jacobi_solve routine computes the Jacobian matrix of the function using RCI and the central difference algorothm.

See usage examples in the examples\solverf\source folderof your Intel® oneAPI Math Kernel Library (oneMKL) directory. Specifically, see sjacobi_rci_f.f and djacobi_rci_f.f.

Input Parameters

handle	Type INTEGER*8.
RCI_Request	INTEGER. Set to 0 before the first call to ?jacobi_solve.

Output Parameters

f1	REAL for sjacobi_solve DOUBLE PRECISION for djacobi_solve Contains the updated function values at x + *eps*.
f2	REAL for sjacobi_solve DOUBLE PRECISION for djacobi_solve Array of size *m*. Contains the updated function values at x - *eps*.
RCI_Request	Provides information about the task completion. When equal to 0, the task has completed successfully.

	RCI_Request= 1 indicates that you should compute the function values at the current *x* point and put the results into *f1*. *RCI_Request*= 2 indicates that you should compute the function values at the current *x* point and put the results into *f2*.
res	INTEGER. Indicates the task completion status. • *res* = TR_SUCCESS - the routine completed the task normally. • *res* = TR_INVALID_OPTION - there was an error in the input parameters. TR_SUCCESS and TR_INVALID_OPTION are defined in the mkl_rci.fi include file.

See Also

?jacobi_init

?jacobi_delete

Releases allocated data.

Syntax

res = sjacobi_delete(*handle*)

res = djacobi_delete(*handle*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The ?jacobi_delete routine releases all memory allocated for the handle. Only after calling this routine is it safe for the user to move or deallocate the memory referenced by *x* and *fjac*.

This routine flags memory as not used, but to actually release all memory you must call the support function mkl_free_buffers.

Input Parameters

handle	Type INTEGER*8.

Output Parameters

res	INTEGER. Informs about the task completion. *res* = TR_SUCCESS means the routine completed the task normally. TR_SUCCESS is defined in the mkl_rci.fi include file.

?jacobi

Computes the Jacobian matrix of the objective function using the central difference algorithm.

Syntax

res = sjacobi(*fcn*, *n*, *m*, *fjac*, *x*, *eps*)

res = djacobi(*fcn*, *n*, *m*, *fjac*, *x*, *eps*)

Include Files

- Fortran: `mkl_rci.fi`, `mkl_rci.f90`

Description

The `?jacobi` routine computes the Jacobian matrix for function *fcn* using the central difference algorithm. This routine has a "Black-Box" interface, where you input the objective function via parameters. Your objective function must have a fixed interface.

See calling and usage examples in the `examples\solverf\source` folderof your Intel® oneAPI Math Kernel Library (oneMKL) directory. Specifically, see `ex_nlsqp_f.f` and `ex_nlsqp_bc_f.f` .

Input Parameters

fcn

User-supplied subroutine to evaluate the function that defines the least squares problem. Called as `fcn` (*m*, *n*, *x*, *f*) with the following parameters:

Parameter	Type	Description
Input Parameters		
m	`INTEGER`	Length of *f*.
n	`INTEGER`	Length of *x*.
x	`REAL` for `sjacobi` `DOUBLE PRECISION` for `djacobi`	Array of size *n*. Vector, at which the function is evaluated. The `fcn` function should not change this parameter.
Output Parameters		
f	`REAL` for `sjacobix` `DOUBLE PRECISION` for `djacobix`	Array of size *m*; contains the function values at *x*.

You need to declare `fcn` as `EXTERNAL` in the calling program.

n

`INTEGER`. Length of *X*.

m

`INTEGER`. Length of *F*.

x

`REAL` for `sjacobi`

`DOUBLE PRECISION` for `djacobi`

Array of size *n*. Vector at which the function is evaluated.

eps

`REAL` for `sjacobi`

`DOUBLE PRECISION` for `djacobi`

Precision of the Jacobian matrix calculation.

Output Parameters

fjac

`REAL` for `sjacobi`

`DOUBLE PRECISION` for `djacobi`

Array of size *m* by *n*. Contains the Jacobian matrix of the function.

res INTEGER. Indicates task completion status.

- *res* = TR_SUCCESS - the routine completed the task normally.
- *res* = TR_INVALID_OPTION - there was an error in the input parameters.
- *res* = TR_OUT_OF_MEMORY - there was a memory error.

TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in the mkl_rci.fi include file.

See Also

?jacobix

?jacobix

Alternative interface for?jacobi *function for passing additional data into the objective function.*

Syntax

res = sjacobix(*fcn*, *n*, *m*, *fjac*, *x*, *eps*, *user_data*)

res = djacobix(*fcn*, *n*, *m*, *fjac*, *x*, *eps*, *user_data*)

Include Files

- Fortran: mkl_rci.fi, mkl_rci.f90

Description

The ?jacobix routine presents an alternative interface for the ?jacobi function that enables you to pass additional data into the objective function *fcn*.

See calling and usage examples in the examples\solverf\source folderof your Intel® oneAPI Math Kernel Library (oneMKL) directory. Specifically, see ex_nlsqp_f90_x.f90 and ex_nlsqp_bc_f90_x.f90.

Input Parameters

fcn User-supplied subroutine to evaluate the function that defines the least squares problem. Called as fcn (*m*, *n*, *x*, *f*, *user_data*) with the following parameters:

Parameter	Type	Description
Input Parameters		
m	INTEGER	Length of *f*.
n	INTEGER	Length of *x*.
x	REAL for sjacobix DOUBLE PRECISION for djacobix	Array of size *n*. Vector, at which the function is evaluated. The fcn function should not change this parameter.
user_data	INTEGER(C_INTPTR_T), for Fortran	Reference to your additional data, if any, passed by value: *user_data*=%VAL(LOC(*data*)). Otherwise, a dummy argument.

Parameter	Type	Description
Output Parameters		
f	REAL for sjacobix DOUBLE PRECISION for djacobix	Array of size *m*; contains the function values at *x*.

You need to declare fcn as EXTERNAL in the calling program.

n INTEGER. Length of *X*.

m INTEGER. Length of *F*.

x REAL for sjacobix

DOUBLE PRECISION for djacobix

Array of size *n*. Vector at which the function is evaluated.

eps REAL for sjacobix

DOUBLE PRECISION for djacobix

Precision of the Jacobian matrix calculation.

user_data INTEGER(C_INTPTR_T). Reference to your additional data, passed by value: *user_data*=%VAL(LOC(*data*)). Otherwise, a dummy argument.

Output Parameters

fjac REAL for sjacobix

DOUBLE PRECISION for djacobix

Array of size *m* by *n*). Contains the Jacobian matrix of the function.

res INTEGER. Indicates task completion status.

- *res* = TR_SUCCESS - the routine completed the task normally.
- *res* = TR_INVALID_OPTION - there was an error in the input parameters.
- *res* = TR_OUT_OF_MEMORY - there was a memory error.

TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in the mkl_rci.fi include file.

Support Functions

Intel® oneAPI Math Kernel Library (oneMKL) support functions are subdivided into the following groups according to their purpose:

Version Information

Threading Control

Error Handling

Character Equality Testing

The following table lists Intel® oneAPI Math Kernel Library (oneMKL) support functions.

oneMKL Support Functions

Function Name	Operation
Version Information	
mkl_get_version_string	Returns the Intel® oneAPI Math Kernel Library (oneMKL) version in a character string.
Threading Control	
mkl_set_num_threads	Specifies the number of OpenMP* threads to use.
mkl_domain_set_num_threads	Specifies the number of OpenMP* threads for a particular function domain.
mkl_set_num_threads_local	Specifies the number of OpenMP* threads for all Intel® oneAPI Math Kernel Library (oneMKL) functions on the current execution thread.
mkl_set_dynamic	Enables Intel® oneAPI Math Kernel Library (oneMKL) to dynamically change the number of OpenMP* threads.
mkl_get_max_threads	Gets the number of OpenMP* threads targeted for parallelism.
mkl_domain_get_max_threads	Gets the number of OpenMP* threads targeted for parallelism for a particular function domain.
mkl_get_dynamic	Determines whether Intel® oneAPI Math Kernel Library (oneMKL) is enabled to dynamically change the number of OpenMP* threads.
mkl_set_num_stripes	Specifies the number of partitions along the leading dimension of the output matrix for parallel ?GEMM functions.
mkl_get_num_stripes	Gets the number of partitions along the leading dimension of the output matrix for parallel ?GEMM functions.
Error Handling	
xerbla	Error handling function called by BLAS, LAPACK, Vector Math, and Vector Statistics functions.
pxerbla	Handles error conditions for the ScaLAPACK routines.
mkl_set_exit_handler	Sets the custom handler of fatal errors.
Character Equality Testing	
lsame	Tests two characters for equality regardless of the case.
lsamen	Tests two character strings for equality regardless of the case.

Function Name	Operation
Timing	
second/dsecnd	Returns elapsed time in seconds. Use to estimate real time between two calls to this function.
mkl_get_cpu_clocks	Returns elapsed CPU clocks.
mkl_get_cpu_frequency	Returns CPU frequency value in GHz.
mkl_get_max_cpu_frequency	Returns the maximum CPU frequency value in GHz.
mkl_get_clocks_frequency	Returns the frequency value in GHz based on constant-rate Time Stamp Counter.
Memory Management	
mkl_free_buffers	Frees unused memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator.
mkl_thread_free_buffers	Frees unused memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator in the current thread.
mkl_mem_stat	Reports the status of the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator.
mkl_peak_mem_usage	Reports the peak memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator.
mkl_disable_fast_mm	Turns off the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator for Intel® oneAPI Math Kernel Library (oneMKL) functions to directly use the system`malloc`/`free` functions.
mkl_malloc	Allocates an aligned memory buffer.
mkl_calloc	Allocates and initializes an aligned memory buffer.
mkl_realloc	Changes the size of memory buffer allocated by `mkl_malloc`/`mkl_calloc`.
mkl_free	Frees the aligned memory buffer allocated by `mkl_malloc`/`mkl_calloc`.
mkl_set_memory_limit	On Linux, sets the limit of memory that Intel® oneAPI Math Kernel Library (oneMKL) can allocate for a specified type of memory.
Single Dynamic Library (SDL) Control	
mkl_set_interface_layer	Sets the interface layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time.
mkl_set_threading_layer	Sets the threading layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time.
mkl_set_xerbla	Replaces the error handling routine. Use with the Single Dynamic Library .
mkl_set_progress	Replaces the progress information routine.

Function Name	Operation
mkl_set_pardiso_pivot	Replaces the routine handling Intel® oneAPI Math Kernel Library (oneMKL) PARDISO pivots with a user-defined routine. Use with the Single Dynamic Library (SDL).
Conditional Numerical Reproducibility (CNR) Control	
mkl_cbwr_set	Configures the CNR mode of Intel® oneAPI Math Kernel Library (oneMKL).
mkl_cbwr_get	Returns the current CNR settings.
mkl_cbwr_get_auto_branch	Automatically detects the CNR code branch for your platform.
Miscellaneous	
mkl_progress	Provides progress information.
mkl_enable_instructions	
mkl_set_env_mode	Set up the mode that ignores environment settings specific to Intel® oneAPI Math Kernel Library (oneMKL).
mkl_verbose	Enable or disable Intel® oneAPI Math Kernel Library (oneMKL) Verbose mode.
mkl_verbose_output_file	Write output in Intel® oneAPI Math Kernel Library (oneMKL) Verbose mode to a file.
mkl_set_mpi	Sets the implementation of the message-passing interface to be used by Intel® oneAPI Math Kernel Library (oneMKL).
mkl_finalize	Terminates Intel® oneAPI Math Kernel Library (oneMKL) execution environment and frees resources allocated by the library.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Using a Fortran Interface Module for Support Functions

To call a support function from your Fortran application, include one of the following statements in your code:

- `INCLUDE mkl_service.fi` or `INCLUDE mkl.fi`
- `USE mkl_service`

The `USE` statement references the `mkl_service.mod`interface module corresponding to your architecture and programming interface. The module provides an application programming interface to Intel® oneAPI Math Kernel Library (oneMKL) support entities, such as subroutines and constants. Because Fortran interface modules are compiler-dependent, Intel® oneAPI Math Kernel Library (oneMKL) offers the`mkl_service.f90` source file for the module, as well as architecture-specific and interface-specific `mkl_service`modules precompiled with the Intel® Fortran or Intel® Visual Fortran compiler. These modules are available in the following subdirectories of the Intel® oneAPI Math Kernel Library (oneMKL) include directory:

Architecture, Interface	Subdirectory of the Intel® oneAPI Math Kernel Library (oneMKL) Installation Directory
IA-32	`include\ia32`
Intel® 64, LP64	`include\intel64\lp64`
Intel® 64, ILP64	`include\intel64\ilp64`

To ensure that your application searches the right module, specify the appropriate subdirectory during compilation as an additional directory for the include path (through the `/I` option on Windows* OS or the `-I` option on Linux* OS or macOS*).

If you are using a non-Intel Fortran compiler, you need to build the module yourself by compiling the `mkl_service.f90`file, available in the Intel® oneAPI Math Kernel Library (oneMKL) include directory.

For more information on compiler-dependent functions and modules, refer to the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*.

Version Information

Intel® oneAPI Math Kernel Library (oneMKL) providesmethods for extracting information about the library version number, such as:

- using the `mkl_get_version` function to obtain an `MKLVersion` structure that contains the version information

A makefile is also provided to automatically build the examples and output summary files containing the version information for the current library.

mkl_get_version_string

Returns the Intel® oneAPI Math Kernel Library (oneMKL) version in a character string.

Syntax

`call mkl_get_version_string( buf )`

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Output Parameters

Name	Type	Description
buf	`CHARACTER*198`	Source string

Description

The function returns a string that contains the Intel® oneAPI Math Kernel Library (oneMKL) version.

For usage details, see the code example below:

Example

```
program test_mkl_get_version_string

character*198  buf
```

```
call mkl_get_version_string(buf)
write(*,'(a)') buf

end
```

Threading Control

Intel® oneAPI Math Kernel Library (oneMKL) provides functions for OpenMP* threading control, discussed in this section.

> **Important**
> If Intel® oneAPI Math Kernel Library (oneMKL) operates within the Intel® Threading Building Blocks (Intel® TBB) execution environment, the environment variables for OpenMP* threading control, such as`OMP_NUM_THREADS`, and Intel® oneAPI Math Kernel Library (oneMKL) functions discussed in this section have no effect. If the Intel TBB threading technology is used, control the number of threads through the Intel TBB application programming interface. Read the documentation for the `tbb::task_scheduler_init` class at https://www.threadingbuildingblocks.org/docs/doxygen/a00150.html to find out how to specify the number of Intel TBB threads.

If Intel® oneAPI Math Kernel Library (oneMKL) operates within an OpenMP* execution environment, you can control the number of threads for Intel® oneAPI Math Kernel Library (oneMKL) using OpenMP* runtime library routines and environment variables (see the OpenMP* specification for details). Additionally Intel® oneAPI Math Kernel Library (oneMKL) provides*optional*threading control functions and environment variables that enable you to specify the number of threads for Intel® oneAPI Math Kernel Library (oneMKL) and to control dynamic adjustment of the number of threads*independently*of the OpenMP* settings. The settings made with the Intel® oneAPI Math Kernel Library (oneMKL) threading control functions and environment variables do not affect OpenMP* settings but take precedence over them.

If functions are used, Intel® oneAPI Math Kernel Library (oneMKL) environment variables may control Intel® oneAPI Math Kernel Library (oneMKL) threading. For details of those environment variables, see the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*.

You can specify the number of threads for Intel® oneAPI Math Kernel Library (oneMKL) function domains with the mkl_set_num_threads or mkl_domain_set_num_threads function. While `mkl_set_num_threads` specifies the number of threads for the entire Intel® oneAPI Math Kernel Library (oneMKL), `mkl_domain_set_num_threads` does it for a specific function domain. The following table lists the function domains that support independent threading control. The table also provides named constants to pass to threading control functions as a parameter that specifies the function domain.

oneMKL Function Domains

Function Domain	Named Constant
Basic Linear Algebra Subroutines (BLAS)	`MKL_DOMAIN_BLAS`
Fast Fourier Transform (FFT) functions, except Cluster FFT functions	`MKL_DOMAIN_FFT`
Vector Math (VM) functions	`MKL_DOMAIN_VML`
Parallel Direct Solver (PARDISO) functions	`MKL_DOMAIN_PARDISO`
All Intel® oneAPI Math Kernel Library (oneMKL) functions except the functions from the domains where the number of threads is set explicitly.	`MKL_DOMAIN_ALL`

Warning
Do not increase the number of OpenMP threads used for cluster_sparse_solver between the first call and the factorization or solution phase. Because the minimum amount of memory required for out-of-core execution depends on the number of OpenMP threads, increasing it after the initial call can cause incorrect results.

Both `mkl_set_num_threads` and `mkl_domain_set_num_threads` functions set the number of threads for all subsequent calls to Intel® oneAPI Math Kernel Library (oneMKL) from all applications threads. Use themkl_set_num_threads_local function to specify different numbers of threads for Intel® oneAPI Math Kernel Library (oneMKL) on different execution threads of your application. The thread-local settings take precedence over the global settings. However, the thread-local settings may have undesirable side effects (see the description of the`mkl_set_num_threads_local` function for details).

By default, Intel® oneAPI Math Kernel Library (oneMKL) canadjust the specified number of threads dynamically. For example, Intel® oneAPI Math Kernel Library (oneMKL) may use fewer threads if the size of the computation is not big enough or not create parallel regions when running within an OpenMP* parallel region. Although Intel® oneAPI Math Kernel Library (oneMKL) may actually use a different number of threads from the number specified, the library does not create parallel regions with more threads than specified. If dynamic adjustment of the number of threads is disabled, Intel® oneAPI Math Kernel Library (oneMKL) attempts to use the specified number of threads in internal parallel regions (for more information, see the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*). Use the mkl_set_dynamic function to control dynamic adjustment of the number of threads.

mkl_set_num_threads

Specifies the number of OpenMP threads to use.*

Syntax

```
call mkl_set_num_threads( nt )
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
nt	INTEGER	*nt* > 0 - The number of threads suggested by the user. *nt*≤ 0 - Invalid value, which is ignored.

Description

This function enables you to specify how many OpenMP threads Intel® oneAPI Math Kernel Library (oneMKL) should use for internal parallel regions. If this number is not set (default), Intel® oneAPI Math Kernel Library (oneMKL) functions use the default number of threads for the OpenMP run-time library. The specified number of threads applies:

- To all Intel® oneAPI Math Kernel Library (oneMKL) functions except the functions from the domains where the number of threads is set withmkl_domain_set_num_threads
- To all execution threads except the threads where the number of threads is set with mkl_set_num_threads_local

The number specified is a hint, and Intel® oneAPI Math Kernel Library (oneMKL) may actually use a smaller number.

NOTE
This function takes precedence over the MKL_NUM_THREADS environment variable.

Example

```
use mkl_service
…
call mkl_set_num_threads(4)
call my_compute_using_mkl  !Intel MKL uses up to 4 OpenMP threads
```

mkl_domain_set_num_threads

Specifies the number of OpenMP threads for a particular function domain.*

Syntax

ierr = mkl_domain_set_num_threads(*nt*, *domain*)

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

Input Parameters

Name	Type	Description
nt	INTEGER	*nt* > 0 - The number of threads suggested by the user. *nt* = 0 - The default number of threads for the OpenMP run-time library. *nt* < 0 - Invalid value, which is ignored.
domain	INTEGER	The named constant that defines the targeted domain.

Description

This function specifies how many OpenMP threads a particular function domain of Intel® oneAPI Math Kernel Library (oneMKL) should use. If this number is not set (default) or if it is set to zero in a call to this function, Intel® oneAPI Math Kernel Library (oneMKL) uses the default number of threads for the OpenMP run-time library. The number of threads specified applies to the specified function domain on all execution threads except the threads where the number of threads is set withmkl_set_num_threads_local. For a list of supported values of the *domain* argument, see Table "Intel MKL Function Domains".

The number of threads specified is only a hint, and Intel® oneAPI Math Kernel Library (oneMKL) may actually use a smaller number.

NOTE
This function takes precedence over the MKL_DOMAIN_NUM_THREADS environment variable.

Return Values

Name	Type	Description
ierr	INTEGER	1 - Indicates no error, execution is successful. 0 - Indicates a failure, possibly because of invalid input parameters.

Example

```
use mkl_service
integer(4) :: status
…
status = mkl_domain_set_num_threads(4, MKL_DOMAIN_BLAS)
call my_compute_with_mkl_blas()    !Intel MKL BLAS functions use up to 4 threads
call my_compute_with_mkl_dft()     !Intel MKL FFT functions use the default number of threads
```

mkl_set_num_threads_local

Specifies the number of OpenMP threads for all Intel® oneAPI Math Kernel Library (oneMKL) functions on the current execution thread.*

Syntax

save_nt = mkl_set_num_threads_local(*nt*)

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

Input Parameters

Name	Type	Description
nt	INTEGER*4	*nt*> 0 - The number of threads for Intel® oneAPI Math Kernel Library (oneMKL) functions to use on the current execution thread. *nt* = 0 - A request to reset the thread-local number of threads and use the global number.

Description

This function sets the number of OpenMP threads that Intel® oneAPI Math Kernel Library (oneMKL) functions should request for parallel computation. The number of threads is thread-local, which means that it only affects the current execution thread of the application. If the thread-local number is not set or if this number is set to zero in a call to this function, Intel® oneAPI Math Kernel Library (oneMKL) functions use the global number of threads. You can set the global number of threads using themkl_set_num_threads or mkl_domain_set_num_threads function.

The thread-local number of threads takes precedence over the global number: if the thread-local number is non-zero, changes to the global number of threads have no effect on the current thread.

Caution
If your application is threaded with OpenMP* andparallelization of Intel® oneAPI Math Kernel Library (oneMKL) is based on nested OpenMP parallelism,different OpenMP parallel regions reuse OpenMP threads. Therefore a thread-local setting in one OpenMP parallel region may continue to affect not only the master thread after the parallel region ends, but also subsequent parallel regions. To avoid performance implications of this side effect, reset the thread-local number of threads before leaving the OpenMP parallel region (see Examples for how to do it).

Return Values

Name	Type	Description
save_nt	INTEGER*4	The value of the thread-local number of threads that was used before this function call. Zero means that the global number of threads was used.

Examples

This example shows how to avoid the side effect of a thread-local number of threads by reverting to the global setting:

```
use omp_lib
use mkl_service
integer(4) :: dummy
…
call mkl_set_num_threads(16)
call my_compute_using_mkl()    ! Intel MKL functions use up to 16 threads
!$omp parallel num_threads(2)
  if (0 == omp_get_thread(num))  dummy = mkl_set_num_threads_local(4)
  if (1 == omp_get_thread(num))  dummy = mkl_set_num_threads_local(12)
  call my_compute_using_mkl()    ! Intel MKL functions use up to 4 threads on thread 0
                    !   and up to 12 threads on thread 1
!$omp end parallel
call my_compute_using_mkl()    ! Intel MKL functions use up to 4 threads (!)
dummy = mkl_set_num_threads_local(0)    ! make master thread use global setting
call my_compute_using_mkl()    ! Now Intel MKL functions use up to 16 threads
```

This example shows how to avoid the side effect of a thread-local number of threads by saving and restoring the existing setting:

```
subroutine my_compute(nt)
    use mkl_service
    integer(4) :: nt, save
save = mkl_set_num_threads_local( nt ) ! save the Intel® oneAPI Math Kernel Library (oneMKL)
number of threads
    call my_compute_using_mkl()    ! Intel MKL functions use up to nt threads on this thread
save = mkl_set_num_threads_local( save ) ! restore the Intel® oneAPI Math Kernel Library
(oneMKL) number of threads
end subroutine my_compute
```

mkl_set_dynamic

Enables Intel® oneAPI Math Kernel Library (oneMKL) to dynamically change the number of OpenMP threads.*

Syntax

```
call mkl_set_dynamic( flag )
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
flag	INTEGER	*flag* = 0 - Requests disabling dynamic adjustment of the number of threads. *flag*≠ 0 - Requests enabling dynamic adjustment of the number of threads.

Description

This function indicates whether Intel® oneAPI Math Kernel Library (oneMKL) can dynamically change the number of OpenMP threads or should avoid doing this. The setting applies to all Intel® oneAPI Math Kernel Library (oneMKL) functions on all execution threads. This function takes precedence over the`MKL_DYNAMIC` environment variable.

Dynamic adjustment of the number of threads is enabled by default. Specifically, Intel® oneAPI Math Kernel Library (oneMKL) may use fewer threads in parallel regions than the number returned by themkl_get_max_threadsfunction. Disabling dynamic adjustment of the number of threads does not ensure that Intel® oneAPI Math Kernel Library (oneMKL) actually uses the specified number of threads, although the library attempts to use that number.

Tip
If you call Intel® oneAPI Math Kernel Library (oneMKL) from within an OpenMP parallel region and want to create internal parallel regions, either disable dynamic adjustment of the number of threads or set the thread-local number of threads (seemkl_set_num_threads_local for how to do it).

Example

```
use mkl_service
…
call mkl_set_num_threads( 8 )
!$omp parallel
  call my_compute_with_mkl    ! Intel MKL uses 1 thread, being called from OpenMP parallel region
  call mkl_set_dynamic(0)    ! disable adjustment of the number of threads
  call my_compute_with_mkl    ! Intel MKL uses 8 threads
!$omp end parallel
```

mkl_get_max_threads

Gets the number of OpenMP threads targeted for parallelism.*

Syntax

```
nt = mkl_get_max_threads()
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Description

This function returns the number of OpenMP threads available for Intel® oneAPI Math Kernel Library (oneMKL) to use in internal parallel regions.

Return Values

Name	Type	Description
nt	INTEGER*4	The maximum number of threads for Intel® oneAPI Math Kernel Library (oneMKL) functions to use in internal parallel regions.

Example

```
use mkl_service
…
if (1 == mkl_get_max_threads()) print *, "Intel MKL does not employ threading"
```

See Also

mkl_set_dynamic

mkl_get_dynamic

Using a Fortran Interface Module for Support Functions

mkl_domain_get_max_threads

Gets the number of OpenMP threads targeted for parallelism for a particular function domain.*

Syntax

nt = mkl_domain_get_max_threads(*domain*)

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
domain	INTEGER	The named constant that defines the targeted domain.

Description

Computational functions of the Intel® oneAPI Math Kernel Library (oneMKL) function domain defined by the*domain* parameter use the value returned by this function as a limit of the number of OpenMP threads they should request for parallel computations. The `mkl_domain_get_max_threads` function returns the thread-local number of threads or, if that value is zero or not set, the global number of threads. To determine this number, the function inspects the environment settings and return values of the function calls below in the order they are listed until it finds a non-zero value:

- A call to mkl_set_num_threads_local
- The last of the calls to mkl_set_num_threads or mkl_domain_set_num_threads(…, MKL_DOMAIN_ALL)
- A call to mkl_domain_set_num_threads(…, *domain*)
- The MKL_DOMAIN_NUM_THREADS environment variable with the MKL_DOMAIN_ALL tag
- The MKL_DOMAIN_NUM_THREADS environment variable (with the specific domain tag)
- The MKL_NUM_THREADS environment variable
- A call to omp_set_num_threads
- The OMP_NUM_THREADS environment variable

Actual number of threads used by the Intel® oneAPI Math Kernel Library (oneMKL) computational functions may vary depending on the problem size and on whether dynamic adjustment of the number of threads is enabled (see the description ofmkl_set_dynamic). For a list of supported values of the *domain* argument, see Table "Intel MKL Function Domains".

Return Values

Name	Type	Description
nt	INTEGER*4	The maximum number of threads for Intel® oneAPI Math Kernel Library (oneMKL) functions from a given domain to use in internal parallel regions. If an invalid value of *domain* is supplied, the function returns the number of threads for MKL_DOMAIN_ALL

Example

```
use mkl_service
…
if (1 < mkl_domain_get_max_threads(MKL_DOMAIN_BLAS)) then
print *, "Intel MKL BLAS functions employ threading"
end if
```

mkl_get_dynamic

Determines whether Intel® oneAPI Math Kernel Library (oneMKL) is enabled to dynamically change the number of OpenMP threads.*

Syntax

```
ret = mkl_get_dynamic()
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

Description

This function returns the status of dynamic adjustment of the number of OpenMP* threads. To determine this status, the function inspects the return value of the following function call and if it is undefined, inspects the environment setting below:

- A call to mkl_set_dynamic
- The MKL_DYNAMIC environment variable

NOTE
Dynamic adjustment of the number of threads is enabled by default.

The dynamic adjustment works as follows. Suppose that the mkl_get_max_threads function returns the number of threads equal to *N*. If dynamic adjustment is enabled, Intel® oneAPI Math Kernel Library (oneMKL) may request up to*N*threads, depending on the size of the problem. If dynamic adjustment is disabled, Intel® oneAPI Math Kernel Library (oneMKL) requests exactly*N* threads for internal parallel regions (provided it uses a threaded algorithm with at least *N*computations that can be done in parallel). However, the OpenMP* run-time library may be configured to supply fewer threads than Intel® oneAPI Math Kernel Library (oneMKL) requests, depending on the OpenMP* setting of dynamic adjustment.

Return Values

Name	Type	Description
ret	INTEGER*4	0 - Dynamic adjustment of the number of threads is disabled. 1 - Dynamic adjustment of the number of threads is enabled.

Example

```
use mkl_service
integer(4) :: nt
…
nt = mkl_get_max_threads()
if (1 == mkl_get_dynamic()) then
  print '("Intel MKL may use less than "I0" threads for a large problem")', nt
else
  print '("Intel MKL should use "I0" threads for a large problem")', nt
end if
```

mkl_set_num_stripes

Specifies the number of partitions along the leading dimension of the output matrix for parallel ?GEMM *functions.*

Syntax

```
call mkl_set_num_stripes( ns )
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

Input Parameters

Name	Type	Description
ns	INTEGER*4	*ns* > 0 - Specifies the number of partitions to use. *ns*= 0 - Instructs Intel® oneAPI Math Kernel Library (oneMKL) to use the default partitioning algorithm.

Name	Type	Description
		ns < 0 - Invalid value; ignored.

Description

This function enables you to specify the number of stripes, or partitions along the leading dimension of the output matrix, for parallel ?GEMMfunctions. If this number is not set (default) or if it is set to zero, Intel® oneAPI Math Kernel Library (oneMKL)?GEMM functions use the default partitioning algorithm. The specified number of partitions only applies to ?GEMM functions.

The number specified is a hint, and Intel® oneAPI Math Kernel Library (oneMKL) may actually use a smaller number.

NOTE
This function takes precedence over the MKL_NUM_STRIPES environment variable.

Example

```
use mkl_service
…
call mkl_set_num_stripes(4)
call dgemm(...)   !Intel MKL uses up to 4 stripes for DGEMM
```

See Also

mkl_get_num_stripes

mkl_get_num_stripes

Gets the number of partitions along the leading dimension of the output matrix for parallel ?GEMM functions.

Syntax

ns = mkl_get_num_stripes( )

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

Description

This function returns the number of stripes, that is, partitions along the leading dimension of the output matrix, for parallel ?GEMM functions. The number of partitions only applies to ?GEMM functions.

The number returned is a hint, and Intel® oneAPI Math Kernel Library (oneMKL) may actually use a smaller number.

Return Values

Name	Type	Description
ns	INTEGER*4	The number of stripes for Intel® oneAPI Math Kernel Library (oneMKL)?GEMM functions to use.

Example

```
use mkl_service
…
INTEGER*4 ns = mkl_get_num_stripes()
if (ns .GT. 0) print *, 'Intel MKL uses', ns, 'number of stripes'
```

See Also

mkl_set_num_stripes

Error Handling

Error Handling for Linear Algebra Routines

xerbla

Error handling function called by BLAS, LAPACK, Vector Math, and Vector Statistics functions.

Syntax

call xerbla(*srname*, *info*)

Include Files

- mkl.fi

Input Parameters

Name	Type	Description
srname	CHARACTER*(*)	The name of the routine that called xerbla
info	INTEGER	The position of the invalid parameter in the parameter list of the calling function or an error code

Description

The xerbla function is an error handler for Intel® oneAPI Math Kernel Library (oneMKL) BLAS, LAPACK, Vector Math, and Vector Statistics functions. These functions call xerbla if an issue is encountered on entry or during the function execution.

xerbla operates as follows:

1. Prints a message that depends on the value of the *info* parameter as explained in the following table.

   NOTE
   A specific message can differ from the listed messages in numeric values and/or function names.

2. Returns to the calling application.

Error Messages Printed by xerbla

Value of *info*	Error Message
1001	`Intel MKL ERROR: Incompatible optional parameters on entry to DGEMM.`
1000 or 1089	`Intel MKL INTERNAL ERROR: Insufficient workspace available in function CGELSD.`
< 0	`Intel MKL INTERNAL ERROR: Condition 1 detected in function DLASD8.`
Other	`The position of the invalid parameter in the parameter list of the calling function.`

Note that `xerbla` is an internal function. You can change or disable printing of an error message by providing your own `xerbla` function. The following examples illustrate usage of `xerbla`.

Example

```
subroutine xerbla (srname, info)
character*(*) srname  !Name of subprogram that called xerbla
integer    info    !Position of the invalid parameter in the parameter list
return    !Return to the calling subprogram end
end
```

See Also

`mkl_set_xerbla`

pxerbla

Error handling routine called by ScaLAPACK routines.

Syntax

`call pxerbla (ictxt, srname, info)`

Include Files

Input Parameters

ictxt

(local)

`INTEGER`

The BLACS context handle, indicating the global context of the operation. The context itself is global.

srname

(global)

`CHARACTER*(*)`

The name of the routine that called `pxerbla`.

info

(global)

`INTEGER`

The position of the invalid parameter in the parameter list of the calling routine.

Description

This routine is an error handler for the *ScaLAPACK* routines. It is called if an input parameter has an invalid value. A message is printed and program execution continues. For ScaLAPACK driver and computational routines, a `RETURN` statement is issued following the call to `pxerbla`.

Control returns to the higher-level calling routine, and you can determine how the program should proceed. However, in the specialized low-level ScaLAPACK routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `pxerbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a non-zero value of *info* on return from a ScaLAPACK routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

Handling Fatal Errors

A fatal error is a circumstance under which Intel® oneAPI Math Kernel Library (oneMKL) cannot continue the computation. For example, a fatal error occurs when Intel® oneAPI Math Kernel Library (oneMKL) cannot load a dynamic library or confronts an unsupported CPU type. In case of a fatal error, the default Intel® oneAPI Math Kernel Library (oneMKL) behavior is to print an explanatory message to the console and call an internal function that terminates the application with a call to the system`exit()` function. Intel® oneAPI Math Kernel Library (oneMKL) enables you to override this behavior by setting a custom handler of fatal errors. The custom error handler can be configured to throw a C++ exception, set a global variable indicating the failure, or otherwise handle cannot-continue situations. It is not necessary for the custom error handler to call the system`exit()` function. Once execution of the error handler completes, a call to Intel® oneAPI Math Kernel Library (oneMKL) returns to the calling program without performing any computations and leaves no memory allocated by Intel® oneAPI Math Kernel Library (oneMKL) and no thread synchronization pending on return.

To specify a custom fatal error handler, call the `mkl_set_exit_handler` function.

mkl_set_exit_handler

Sets the custom handler of fatal errors.

Syntax

```
external :: myexit
interface = mkl_set_exit_handler( myexit )
```

Fortran Include Files/Modules

None.

Input Parameters

Name	Interface	Description

myexit	`interface`
	`subroutine myexit(iwhy)`
	`integer,value :: iwhy`
	`end subroutine myexit`
	`end interface`
		The error handler to set.

Description

This function sets the custom handler of fatal errors.

The following example shows how to use a custom handler of fatal errors in your application:

```
subroutine myexit(rsn)
integer,value :: rsn
call msgbox("Application is terminating")
```

```
end myexit

program app
external :: myexit
call mkl_set_exit_handler(myexit)
!... compute using Intel MKL...
```

Character Equality Testing

lsame

Tests two characters for equality regardless of the case.

Syntax

val = lsame(*ca*, *cb*)

Include Files

- mkl.fi

Input Parameters

Name	Type	Description
ca, *cb*	CHARACTER*1	The single characters to be compared

Description

This logical function checks whether two characters are equal regardless of the case.

Return Values

Name	Type	Description
val	LOGICAL	Result of the comparison: • .TRUE. if *ca* is the same letter as *cb*, maybe except for the case. • .FALSE. if *ca* and *cb* are different letters for whatever cases.

lsamen

Tests two character strings for equality regardless of the case.

Syntax

val = lsamen(*n*, *ca*, *cb*)

Include Files

- mkl.fi

Input Parameters

Name	Type	Description
n	INTEGER	The number of characters in *ca* and *cb* to be compared.
ca, *cb*	CHARACTER*(*)	Character strings of length at least *n* to be compared. Only the first *n* characters of each string will be accessed.

Description

This logical function tests whether the first *n* letters of one string are the same as the first *n* letters of the other string, regardless of the case.

Return Values

Name	Type	Description
val	LOGICAL	Result of the comparison: • .TRUE. if the first *n* letters in *ca* and *cb* character strings are equal, maybe except for the case, or if the length of character string *ca* or *cb* is less than *n*. • .FALSE. if the first *n* letters in *ca* and *cb* character strings are different for whatever cases.

Timing

second/dsecnd

Returns elapsed time in seconds. Use to estimate real time between two calls to this function.

Syntax

```
val = second()
val = dsecnd()
```

Include Files

- mkl.fi

Description

The second/dsecnd function returns time in seconds to be used to estimate real time between two calls to the function. The difference between these functions is in the precision of the floating-point type of the result: while second returns the single-precision type, dsecnd returns the double-precision type.

Use these functions to measure durations. To do this, call each of these functions twice. For example, to measure performance of a routine, call the appropriate function directly before a call to the routine to be measured, and then after the call of the routine. The difference between the returned values shows real time spent in the routine.

Initializations may take some time when the second/dsecnd function runs for the first time. To eliminate the effect of this extra time on your measurements, make the first call to second/dsecnd in advance.

Do not use second to measure short time intervals because the single-precision format is not capable of holding sufficient timer precision.

Return Values

Name	Type	Description
val	REAL for second DOUBLE PRECISION for dsecnd	Elapsed real time in seconds

mkl_get_cpu_clocks

Returns elapsed CPU clocks.

Syntax

```
call mkl_get_cpu_clocks( clocks )
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

Output Parameters

Name	Type	Description
clocks	INTEGER*8	Elapsed CPU clocks

Description

The mkl_get_cpu_clocks function returns the elapsed CPU clocks.

This may be useful when timing short intervals with high resolution. The mkl_get_cpu_clocks function is also applied in pairs like second/dsecnd. Note that out-of-order code execution on IA-32 or Intel® 64 architecture processors may disturb the exact elapsed CPU clocks value a little bit, which may be important while measuring extremely short time intervals.

mkl_get_cpu_frequency

Returns the current CPU frequency value in GHz.

Syntax

```
freq = mkl_get_cpu_frequency()
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

Description

The function mkl_get_cpu_frequency returns the current CPU frequency in GHz.

NOTE
The returned value may vary from run to run if power management or Intel® Turbo Boost Technology is enabled.

Return Values

Name	Type	Description
freq	DOUBLE PRECISION	Current CPU frequency value in GHz

mkl_get_max_cpu_frequency

Returns the maximum CPU frequency value in GHz.

Syntax

```
freq = mkl_get_max_cpu_frequency()
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Description

The function `mkl_get_max_cpu_frequency` returns the maximum CPU frequency in GHz.

Return Values

Name	Type	Description
freq	DOUBLE PRECISION	Maximum CPU frequency value in GHz

mkl_get_clocks_frequency

Returns the frequency value in GHz based on constant-rate Time Stamp Counter.

Syntax

```
freq = mkl_get_clocks_frequency()
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Description

The function `mkl_get_clocks_frequency` returns the CPU frequency value (in GHz) based on constant-rate Time Stamp Counter (TSC). Use of the constant-rate TSC ensures that each clock tick is constant even if the CPU frequency changes. Therefore, the returned frequency is constant.

NOTE
Obtaining the frequency may take some time when `mkl_get_clocks_frequency` is called for the first time. The same holds for functions `second/dsecnd`, which call `mkl_get_clocks_frequency`.

Return Values

Name	Type	Description
freq	DOUBLE PRECISION	Frequency value in GHz

`second/dsecnd`
Using a Fortran Interface Module for Support Functions

Memory Management

This section describes the Intel® oneAPI Math Kernel Library (oneMKL) memory functions. See the*Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for more memory usage information.

mkl_free_buffers

Frees unused memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) on the Host.

Syntax

```
call mkl_free_buffers
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Description

To improve performance of Intel® oneAPI Math Kernel Library (oneMKL) on CPU, the Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. Intel® oneAPI Math Kernel Library (oneMKL) also allocates temporary buffers on the host memory to improve performance of GPU kernels. The `mkl_free_buffers` function frees both types of memory.

See the*Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for details.

You should call `mkl_free_buffers` after the last call to Intel® oneAPI Math Kernel Library (oneMKL) functions. In large applications, if you suspect that the memory may get insufficient, you may call this function earlier, but anticipate a drop in performance that may occur due to reallocation of buffers for subsequent calls to Intel® oneAPI Math Kernel Library (oneMKL) functions.

Usage of mkl_free_buffers with FFT Functions (C Example)

```
DFTI_DESCRIPTOR_HANDLE hand1;
DFTI_DESCRIPTOR_HANDLE hand2;
void mkl_free_buffers(void);
. . . . . .
/* Using Intel MKL FFT */
Status = DftiCreateDescriptor(&hand1, DFTI_SINGLE, DFTI_COMPLEX, dim, m1);
Status = DftiCommitDescriptor(hand1);
Status = DftiComputeForward(hand1, s_array1);
. . . . . .
Status = DftiCreateDescriptor(&hand2, DFTI_SINGLE, DFTI_COMPLEX, dim, m2);
Status = DftiCommitDescriptor(hand2);
. . . . . .
Status = DftiFreeDescriptor(&hand1);
. . . . . .
Status = DftiComputeBackward(hand2, s_array2));
Status = DftiFreeDescriptor(&hand2);
/* Here you finish using Intel MKL FFT */
/* Memory leak will be triggered by any memory control tool */
/* Use mkl_free_buffers() to avoid memory leaking */
mkl_free_buffers();
```

mkl_thread_free_buffers

Frees unused memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator in the current thread.

Syntax

```
call mkl_thread_free_buffers
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Description

To improve performance of Intel® oneAPI Math Kernel Library (oneMKL), the Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. The`mkl_thread_free_buffers` function frees unused memory allocated by the Memory Allocator in the current thread only.

You should call `mkl_thread_free_buffers`after the last call to Intel® oneAPI Math Kernel Library (oneMKL) functions in the current thread. In large applications, if you suspect that the memory may get insufficient, you may call this function earlier, but anticipate a drop in performance that may occur due to reallocation of buffers for subsequent calls to Intel® oneAPI Math Kernel Library (oneMKL) functions.

`mkl_free_buffers`

Using a Fortran Interface Module for Support Functions

mkl_disable_fast_mm

Turns off the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator for Intel® oneAPI Math Kernel Library (oneMKL) functions to directly use the system`malloc/free` *functions.*

Syntax

mm = mkl_disable_fast_mm

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

Description

The mkl_disable_fast_mmfunction turns the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator off for Intel® oneAPI Math Kernel Library (oneMKL) functions to directly use the systemmalloc/ freefunctions. Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. The Memory Allocator is turned on by default for better performance. To turn it off, you can use themkl_disable_fast_mm function or the MKL_DISABLE_FAST_MM environment variable (See the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for details.) Call mkl_disable_fast_mmbefore calling any Intel® oneAPI Math Kernel Library (oneMKL) functions that require allocation of memory buffers.

> **NOTE**
> Turning the Memory Allocator off negatively impacts performance of some Intel® oneAPI Math Kernel Library (oneMKL) routines, especially for small problem sizes.

Return Values

Name	Type	Description
mm	INTEGER*4	1 - The Memory Allocator is successfully turned off. 0 - Turning the Memory Allocator off failed.

mkl_mem_stat

Reports the status of the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator.

Syntax

AllocatedBytes = mkl_mem_stat(*AllocatedBuffers*)

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

Output Parameters

Name	Type	Description
AllocatedBuffers	INTEGER*4	The number of buffers allocated by Intel® oneAPI Math Kernel Library (oneMKL).

Description

The function returns the number of buffers allocated by Intel® oneAPI Math Kernel Library (oneMKL) and the amount of memory in these buffers. Intel® oneAPI Math Kernel Library (oneMKL) can allocate the memory buffers internally or in a call tomkl_malloc/mkl_calloc. If no buffers are allocated at the moment, the `mkl_mem_stat` function returns 0. Call `mkl_mem_stat`to check the Intel® oneAPI Math Kernel Library (oneMKL) memory status.

> **NOTE**
> If you free all the memory allocated in calls to `mkl_malloc` or `mkl_calloc` and then call `mkl_free_buffers`, a subsequent call to `mkl_mem_stat` normally returns 0.

Return Values

Name	Type	Description
AllocatedBytes	INTEGER*8	The amount of allocated memory (in bytes).

mkl_peak_mem_usage

Reports the peak memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator.

Syntax

AllocatedBytes = mkl_peak_mem_usage(*mode*)

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
mode	INTEGER*4	Requested mode of the function's operation. Possible values: • `MKL_PEAK_MEM_ENABLE` - start gathering the peak memory data • `MKL_PEAK_MEM_DISABLE` - stop gathering the peak memory data • `MKL_PEAK_MEM` - return the peak memory • `MKL_PEAK_MEM_RESET` - return the peak memory and reset the counter to start gathering the peak memory data from scratch

Description

The `mkl_peak_mem_usage`function reports the peak memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator.

Gathering the peak memory data is turned off by default. If you need to know the peak memory, explicitly turn the data gathering mode on by calling the function with the `MKL_PEAK_MEM_ENABLE` value of the parameter. Use the `MKL_PEAK_MEM` and `MKL_PEAK_MEM_RESET` values only when the data gathering mode is turned on. Otherwise the function returns -1. The data gathering mode leads to performance degradation, so when the mode is turned on, you can turn it off by calling the function with the `MKL_PEAK_MEM_DISABLE` value of the parameter.

NOTE

- If Intel® oneAPI Math Kernel Library (oneMKL) is running in a threaded mode, the`mkl_peak_mem_usage` function may return different amounts of memory from run to run.
- The function reports the peak memory for the entire application, not just for the calling thread.

Return Values

Name	Type	Description
AllocatedBytes	INTEGER*8	The peak memory allocated by the Memory Allocator (in bytes) or -1 in case of errors.

Using a Fortran Interface Module for Support Functions

mkl_malloc

Allocates an aligned memory buffer.

Syntax

a_ptr = mkl_malloc(*alloc_size*, *alignment*)

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
alloc_size	INTEGER*4 for 32-bit systems INTEGER*8 for 64-bit systems	Size of the buffer to be allocated.
alignment	INTEGER*4	Alignment of the buffer.

Description

The function allocates an *alloc_size*-byte buffer aligned on the *alignment*-byte boundary.

If *alignment* is not a power of 2, the 64-byte alignment is used.

Return Values

Name	Type	Description
a_ptr	POINTER	Pointer to the allocated buffer if *alloc_size* ≥ 1, NULL if *alloc_size* < 1.

See Also

mkl_free
Usage Examples for the Memory Functions
Using a Fortran Interface Module for Support Functions

mkl_calloc

Allocates and initializes an aligned memory buffer.

Syntax

a_ptr = mkl_calloc(*num*, *size*, *alignment*)

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

Input Parameters

Name	Type	Description
num	INTEGER*4 for 32-bit systems INTEGER*8 for 64-bit systems	The number of elements in the buffer to be allocated.
size	INTEGER*4 for 32-bit systems INTEGER*8 for 64-bit systems	The size of the element.
alignment	INTEGER*4	Alignment of the buffer.

Description

The function allocates a *num***size*-byte buffer, aligned on the *alignment*-byte boundary, and initializes the buffer with zeros.

If *alignment* is not a power of 2, the 64-byte alignment is used.

Return Values

Name	Type	Description
a_ptr	POINTER	Pointer to the allocated buffer if *size* ≥ 1, NULL if *size* < 1.

See Also

mkl_malloc
mkl_realloc
mkl_free
Usage Examples for the Memory Functions

Using a Fortran Interface Module for Support Functions

mkl_realloc

Changes the size of memory buffer allocated by `mkl_malloc/mkl_calloc`.

Syntax

`a_ptr = mkl_realloc( ptr, size )`

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
ptr	POINTER	Pointer to the memory buffer allocated by the `mkl_malloc` or `mkl_calloc` function or a `NULL` pointer.
size	`INTEGER*4` for 32-bit systems `INTEGER*8` for 64-bit systems	New size of the buffer.

Description

The function changes the size of the memory buffer allocated by the `mkl_malloc` or `mkl_calloc` function to *size* bytes. The first bytes of the returned buffer up to the minimum of the old and new sizes keep the content of the input buffer. The returned memory buffer can have a different location than the input one. If *ptr* is `NULL`, the function works as `mkl_malloc`.

Return Values

Name	Type	Description
a_ptr	POINTER	• Pointer to the re-allocated buffer if re-allocation is successful. • `NULL` if re-allocation is unsuccessful.

See Also

`mkl_malloc`

`mkl_calloc`

`mkl_free`

Usage Examples for the Memory Functions

Using a Fortran Interface Module for Support Functions

mkl_free

Frees the aligned memory buffer allocated by `mkl_malloc/mkl_calloc`.

Syntax

`call mkl_free( a_ptr )`

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
a_ptr	POINTER	Pointer to the buffer to be freed.

Description

The function frees the buffer pointed by *a_ptr* and allocated by the `mkl_malloc()` or `mkl_calloc()` function and does nothing if *a_ptr* is `NULL`.

See Also

`mkl_malloc`

`mkl_calloc`

Usage Examples for the Memory Functions

Using a Fortran Interface Module for Support Functions

mkl_set_memory_limit

On Linux, sets the limit of memory that Intel® oneAPI Math Kernel Library (oneMKL) can allocate for a specified type of memory.

Syntax

```
stat = mkl_set_memory_limit( mem_type, limit )
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
mem_type	INTEGER*4	Type of memory to limit. Possible values: `MKL_MEM_MCDRAM` - Multi-Channel Dynamic Random Access Memory (MCDRAM).
limit	INTEGER*4 for 32-bit systems INTEGER*8 for 64-bit systems.	Memory limit in megabytes.

Description

This function sets the limit for the amount of memory that Intel® oneAPI Math Kernel Library (oneMKL) can allocate for the specified memory type. The limit bounds both internal allocations (inside Intel® oneAPI Math Kernel Library (oneMKL) computation routines) and external allocations (in a call to`mkl_malloc`, `mkl_calloc`, or `mkl_realloc`). By default no limit is set for memory allocation.

Call `mkl_set_memory_limit`at most once, prior to calling any other Intel® oneAPI Math Kernel Library (oneMKL) function in your application except `mkl_set_interface_layer` and `mkl_set_threading_layer`.

NOTE

- Allocation in MCDRAM requires `libmemkind` and `libjemalloc` dynamic libraries which are a part of Intel® Manycore Platform Software Package (Intel® MPSP) for Linux*.
- The `mkl_set_memory_limit` function takes precedence over the `MKL_FAST_MEMORY_LIMIT` environment variable.

Return Values

Type	Description
`INTEGER*4`	Status of the function completion: • 1 - the limit is set • 0 - the limit is not set

Single Dynamic Library Control

Intel® oneAPI Math Kernel Library (oneMKL) provides the Single Dynamic Library (SDL), which enables setting the interface and threading layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time. See*Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for details of SDL and layered model concept. This section describes the functions supporting SDL.

mkl_set_interface_layer

Sets the interface layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time. Use with the Single Dynamic Library.

Syntax

```
interface = mkl_set_interface_layer( required_interface )
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
required_interface	INTEGER	Determines the interface layer. Possible values depend on the system architecture. Some of the values are only available on Linux* OS: • Intel® 64 architecture: `MKL_INTERFACE_LP64` for the Intel LP64 interface. `MKL_INTERFACE_ILP64` for the Intel ILP64 interface. `MKL_INTERFACE_LP64+MKL_INTERFACE_GNU` for the GNU* LP64 interface on Linux OS. `MKL_INTERFACE_ILP64+MKL_INTERFACE_GNU` for the GNU ILP64 interface on Linux OS. • IA-32 architecture: `MKL_INTERFACE_LP64` for the Intel interface on Linux OS. `MKL_INTERFACE_LP64+MKL_INTERFACE_GNU` or `MKL_INTERFACE_GNU` for the GNU interface on Linux OS.

Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_interface_layer`function sets the specified interface layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time.

Call this function prior to calling any other Intel® oneAPI Math Kernel Library (oneMKL) function in your application except`mkl_set_threading_layer`. You can call `mkl_set_interface_layer` and `mkl_set_threading_layer` in any order.

The `mkl_set_interface_layer` function takes precedence over the `MKL_INTERFACE_LAYER` environment variable.

See *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for the layered model concept and usage details of the SDL.

Return Values

Type	Description
INTEGER	• Current interface layer if it is set in a call to mkl_set_interface_layer or specified by environment variables or defaults. Possible values are specified in Input Parameters. • -1, if the layer was not specified prior to the call and the input parameter is incorrect.

mkl_set_threading_layer

Sets the threading layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time. Use with the Single Dynamic Library (SDL).

Syntax

```
threading = mkl_set_threading_layer( required_threading )
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

Input Parameters

Name	Type	Description
required_threading	INTEGER	Determines the threading layer. Possible values: MKL_THREADING_INTEL for Intel threading. MKL_THREADING_SEQUENTIALfor the sequential mode of Intel® oneAPI Math Kernel Library (oneMKL). MKL_THREADING_TBB for threading with the Intel® Threading Building Blocks. MKL_THREADING_PGI for PGI threading on Windows* or Linux* operating system only. Do not use this value with the SDL for Intel® Many Integrated Core (Intel® MIC) Architecture. **NOTE** PGI* support is deprecated and will be removed in the oneMKL 2025.0 release. MKL_THREADING_GNU for GNU threading on Linux* operating system only. Do not use this value with the SDL for Intel MIC Architecture.

Description

If you are using the Single Dynamic Library (SDL), the mkl_set_threading_layerfunction sets the specified threading layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time.

Call this function prior to calling any other Intel® oneAPI Math Kernel Library (oneMKL) function in your application except `mkl_set_interface_layer`.

You can call `mkl_set_threading_layer` and `mkl_set_interface_layer` in any order.

The `mkl_set_threading_layer` function takes precedence over the `MKL_THREADING_LAYER` environment variable.

See *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for the layered model concept and usage details of the SDL.

Return Values

Type	Description
`INTEGER`	• Current threading layer if it is set in a call to `mkl_set_threading_layer` or specified by environment variables or defaults. Possible values are specified in Input Parameters. • -1, if the layer was not specified prior to the call and the input parameter is incorrect.

mkl_set_xerbla

Replaces the error handling routine. Use with the Single Dynamic Library .

Syntax

`old_xerbla_ptr = mkl_set_xerbla( new_xerbla_ptr )`

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
new_xerbla_ptr	`XerblaEntry`	Pointer to the error handling routine to be used.

Description

The `mkl_set_xerbla`function replaces the error handling routine that is called by Intel® oneAPI Math Kernel Library (oneMKL) functions with the routine specified by the parameter.

See *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for details about SDL.

Return Values

The function returns the pointer to the replaced error handling routine.

See Also

`xerbla`

Using a Fortran Interface Module for Support Functions

mkl_set_progress

Replaces the progress information routine.

Syntax

```
old_progress_ptr mkl_set_progress( new_progress_ptr )
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
new_progress_ptr	ProgressEntry	Pointer to the progress information routine to be used.

Description

The `mkl_set_progress` function replaces the currently used progress information routine with the routine specified by the parameter.

Usually a user-supplied `mkl_progress` function redefines the default `mkl_progress` function automatically. However, you must call `mkl_set_progress` to replace the default `mkl_progress` on Windows* in any of the following cases:

- You are using the Single Dynamic Library (SDL) `mkl_rt.lib`.
- You link dynamically with ScaLAPACK.

See *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for details of SDL.

Return Values

The function returns the pointer to the replaced progress information routine.

See Also

`mkl_progress`

Using a Fortran Interface Module for Support Functions

mkl_set_pardiso_pivot

Replaces the routine handling Intel® oneAPI Math Kernel Library (oneMKL) PARDISO pivots with a user-defined routine. Use with the Single Dynamic Library (SDL).

Syntax

```
old_pardiso_pivot_ptr = mkl_set_pardiso_pivot( new_pardiso_pivot_ptr )
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
new_pardiso_pivot_ptr	PardisopivotEntry	Pointer to the pivot setting routine to be used.

Description

If you are using the Single Dynamic Library (SDL), the mkl_set_pardiso_pivotfunction replaces the pivot setting routine that is called by Intel® oneAPI Math Kernel Library (oneMKL) functions with the routine specified by the parameter.

See *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for usage details of the SDL.

Return Values

Type	Description
PardisopivotEntry	Pointer to the replaced pivot setting routine.

See Also

mkl_pardiso_pivot

Conditional Numerical Reproducibility Control

The CNR mode of Intel® oneAPI Math Kernel Library (oneMKL) ensures bitwise reproducible results from run to run of Intel® oneAPI Math Kernel Library (oneMKL) functions on a fixed number of threads for a specific Intel instruction set architecture (ISA) under the following conditions:

- Calls to Intel® oneAPI Math Kernel Library (oneMKL) occur in a single executable
- The number of computational threads used by the library does not change in the run

Intel® oneAPI Math Kernel Library (oneMKL) offers both functions and environment variables to support conditional numerical reproducibility. See the*Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for more information on bitwise reproducible results of computations and for details about the environment variables.

The support functions enable you to configure the CNR mode and also provide information on the current and optimal CNR branch on your system. Usage Examples for CNR Support Functions illustrate usage of these functions.

Important
Call the functions that define the behavior of CNR before any of the math library functions that they control.

Intel® oneAPI Math Kernel Library (oneMKL) provides named constants for use as input and output parameters of the functions instead of integer values. SeeNamed Constants for CNR Control for a list of the named constants.

Although you can configure the CNR mode using either the support functions or the environment variables, the functions offer more flexible configuration and control than the environment variables. Settings specified by the functions take precedence over the settings specified by the environment variables.

Use Intel® oneAPI Math Kernel Library (oneMKL) in the CNR mode only in case a need for bitwise reproducible results is critical. Otherwise, run Intel® oneAPI Math Kernel Library (oneMKL) as usual to avoid performance degradation.

While you can supply unaligned input and output data to Intel® oneAPI Math Kernel Library (oneMKL) functions running in the CNR mode, use of aligned data is recommended. Refer toReproducibility Conditions for more details.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

mkl_cbwr_set

Configures the CNR mode of Intel® oneAPI Math Kernel Library (oneMKL).

Syntax

```
status = mkl_cbwr_set( setting )
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
setting	INTEGER*4	CNR branch to set. See Named Constants for CNR Control for a list of named constants that specify the settings.

Description

The `mkl_cbwr_set` function configures the CNR mode. In this release, it sets the CNR branch and turns on the CNR mode.

NOTE
Settings specified by the `mkl_cbwr_set` function take precedence over the settings specified by the `MKL_CBWR` environment variable.

Return Values

Name	Type	Description
status	INTEGER*4	The status of the function completion: • `MKL_CBWR_SUCCESS` - the function completed successfully. • `MKL_CBWR_ERR_INVALID_INPUT` - an invalid setting is requested. • `MKL_CBWR_ERR_UNSUPPORTED_BRANCH` - the input value of the branch does not match the instruction set architecture (ISA) of your system. See Named Constants for CNR Control for more details.

Name	Type	Description
		• MKL_CBWR_ERR_MODE_CHANGE_FAILURE - the mkl_cbwr_setfunction requested to change the current CNR branch after a call to some Intel® oneAPI Math Kernel Library (oneMKL) function other than a CNR function.

See Also

Usage Examples for CNR Support Functions
Using a Fortran Interface Module for Support Functions

mkl_cbwr_get

Returns the current CNR settings.

Syntax

```
setting = mkl_cbwr_get( option )
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

Input Parameters

Name	Type	Description
option	INTEGER*4	Specifies the CNR settings requested. Named constants define possible values of *option*: • MKL_CBWR_BRANCH - returns the current CNR branch only. • MKL_CBWR_ALL - returns all CNR settings including strict CNR setting.

Description

The mkl_cbwr_get function returns the requested CNR settings. The function returns MKL_CBWR_ERR_INVALID_INPUT if an invalid option is specified.

NOTE
To enable CNR mode, use the mkl_cbwr_set function or environment variables. For more details, see the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*.

Return Values

Name	Type	Description
setting	INTEGER*4	Requested CNR settings. See Named Constants for CNR Control for a list of named constants that specify the settings.

Name	Type	Description
		If the value of the *option* parameter is not permitted, contains the MKL_CBWR_ERR_INVALID_INPUT error code.

See Also

Usage Examples for CNR Support Functions

mkl_cbwr_set

mkl_cbwr_get_auto_branch

Automatically detects the CNR code branch for your platform.

Syntax

setting = mkl_cbwr_get_auto_branch( )

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod
- Module (source): mkl_service.f90

Description

The mkl_cbwr_get_auto_branch function uses a run-time CPU check to return a CNR branch that is optimized for the processor where the program is currently running.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Return Values

Name	Type	Description
setting	INTEGER*4	Automatically detected CNR branch. May be any *specific* branch listed in Named Constants for CNR Control.

See Also

Usage Examples for CNR Support Functions

Using a Fortran Interface Module for Support Functions

Named Constants for CNR Control

Use the conditional numerical reproducibility (CNR) functionality in Intel® oneAPI Math Kernel Library (oneMKL) to obtain reproducible results from MKL routines. When enabling CNR, you choose a specific code branch of Intel® oneAPI Math Kernel Library (oneMKL) that corresponds to the instruction set architecture (ISA) that you target. Use these named constants to specify the code branch and other CNR options.

Named Constant	Value	Description
CNR Branches		
MKL_CBWR_OFF	0	Disable CNR mode

Named Constant	Value	Description
MKL_CBWR_BRANCH_OFF	1	CNR mode is disabled
MKL_CBWR_AUTO	2	Choose branch automatically. CNR mode uses the standard ISA-based dispatching model while ensuring fixed cache sizes, deterministic reductions, and static scheduling
MKL_CBWR_COMPATIBLE	3	Intel® Streaming SIMD Extensions 2 (Intel® SSE2) without rcpps/rsqrtps instructions
MKL_CBWR_SSE2	4	Intel SSE2
MKL_CBWR_SSE3	5	DEPRECATED. Intel® Streaming SIMD Extensions 3 (Intel® SSE3). This setting is kept for backward compatibility and is equivalent to MKL_CBWR_SSE2.
MKL_CBWR_SSSE3	6	Supplemental Streaming SIMD Extensions 3 (SSSE3)
MKL_CBWR_SSE4_1	7	Intel® Streaming SIMD Extensions 4-1 (SSE4-1)
MKL_CBWR_SSE4_2	8	Intel® Streaming SIMD Extensions 4-2 (SSE4-2)
MKL_CBWR_AVX	9	Intel® Advanced Vector Extensions (Intel® AVX)
MKL_CBWR_AVX2	10	Intel® Advanced Vector Extensions 2 (Intel® AVX2)
MKL_CBWR_AVX512_MIC	11	DEPRECATED. Intel® Advanced Vector Extensions 512 (Intel® AVX-512) on Intel® Xeon Phi™ processors. This setting is kept for backward compatibility and is equivalent to MKL_CBWR_AVX2.
MKL_CBWR_AVX512	12	Intel AVX-512 on Intel® Xeon® processors
MKL_CBWR_AVX512_MIC_E1	13	DEPRECATED. Intel® Advanced Vector Extensions 512 (Intel® AVX-512) for Intel® Many Integrated Core Architecture (Intel® MIC Architecture) with support of AVX512_4FMAPS and AVX512_4VNNIW instruction groups enabled processors. This setting is kept for backward compatibility and is equivalent to MKL_CBWR_AVX2.
MKL_CBWR_AVX512_E1	14	Intel® Advanced Vector Extensions 512 (Intel® AVX-512) with support of Vector Neural Network Instructions enabled processors
CNR Flags		
MKL_CBWR_STRICT	65536 or 0x10000	Strict CNR mode enabled. See Reproducibility Conditions for more information.

When specifying the CNR branch with the named constants, be aware of the following:

- Reproducible results are provided under Reproducibility Conditions.
- Settings other than MKL_CBWR_AUTO or MKL_CBWR_COMPATIBLE are available only for Intel processors.
- Intel and Intel compatible CPUs have a few instructions, such as approximation instructions rcpps/rsqrtps, that may return different results. Setting the branch to MKL_CBWR_COMPATIBLEensures that Intel® oneAPI Math Kernel Library (oneMKL) does not use these instructions and forces a single Intel SSE2-only code path to be executed.

Usage Examples for CNR Support Functions

Reproducibility Conditions

To get reproducible results from run to run, ensure that the number of threads is fixed and constant. Specifically:

- If you are running your program with OpenMP* parallelization on different processors, explicitly specify the number of threads.
- To ensure that your application has deterministic behavior with OpenMP* parallelization and does not adjust the number of threads dynamically at run time, set `MKL_DYNAMIC` and `OMP_DYNAMIC` to FALSE. This is especially needed if you are running your program on different systems.
- If you are running your program with the Intel® Threading Building Blocks parallelization, numerical reproducibility is not guaranteed.

Strict CNR Mode

In strict CNR mode, oneAPI Math Kernel Library provides bitwise reproducible results for a limited set of functions and code branches even when the number of threads changes. These routines and branches support strict CNR mode (64-bit libraries only):

- `?gemm`, `?symm`, `?hemm`, `?trsm`, and their CBLAS equivalents (`cblas_?gemm`, `cblas_?symm`, `cblas_?hemm`, and `cblas_?trsm`.
- Intel® Advanced Vector Extensions 2 (Intel® AVX2) or Intel® Advanced Vector Extensions 512 (Intel® AVX-512).

When using other routines or CNR branches,oneAPI Math Kernel Library operates in standard (non-strict) CNR mode, subject to the restrictions described above. Enabling strict CNR mode can reduce performance.

NOTE

- As usual, you should align your data, even in CNR mode, to obtain the best possible performance. While CNR mode also fully supports unaligned input and output data, the use of it might reduce the performance of some oneAPI Math Kernel Library functions on earlier Intel processors. To ensure proper alignment of arrays, allocate memory for them using `mkl_malloc`/`mkl_calloc`.
- Conditional Numerical Reproducibility does not ensure that bitwise-identical NaN values are generated when the input data contains NaN values.
- If dynamic memory allocation fails on one run but succeeds on another run, you may fail to get reproducible results between these two runs.

Usage Examples for CNR Support Functions

The following examples illustrate usage of support functions for conditional numerical reproducibility.

Setting Automatically Detected CNR Branch

```
    PROGRAM MAIN
    INCLUDE 'mkl.fi'
    INTEGER*4 MY_CBWR_BRANCH
C Find the available MKL_CBWR_BRANCH automatically
    MY_CBWR_BRANCH = MKL_CBWR_GET_AUTO_BRANCH()
C User code without Intel MKL calls
C Piece of the code where CNR of Intel MKL is needed
C The performance of Intel MKL functions might be reduced for CNR mode
    IF (MKL_CBWR_SET (MY_CBWR_BRANCH) .NE. MKL_CBWR_SUCCESS) THEN
        PRINT *, 'Error in setting MKL_CBWR_BRANCH! Aborting…'
        RETURN
    ENDIF
C CNR calls to Intel MKL + any other code
    END
```

Use of the mkl_cbwr_get Function

```
    PROGRAM MAIN
    INCLUDE 'mkl.fi'
    INTEGER*4 MY_CBWR_BRANCH
C Piece of the code where CNR of Intel MKL is analyzed
    MY_CBWR_BRANCH = MKL_CBWR_GET(MKL_CBWR_BRANCH)
    IF (MY_CBWR_BRANCH .EQ. MKL_CBWR_AUTO) THEN
C actions in case of automatic mode
    ELSE IF (MY_CBWR_BRANCH .EQ. MKL_CBWR_SSSE3) THEN
C actions for SSSE3 code
    ELSE
C all other cases
    ENDIF
C User code
    END
```

Miscellaneous

mkl_progress

Provides progress information.

Syntax

stopflag = mkl_progress(*thread_process*, *step*, *stage*)

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
thread_process	INTEGER*4	Indicates the number of thread or process the progress routine is called from: • The thread number for non-cluster components linked with OpenMP threading layer • Zero for non-cluster components linked with sequential threading layer • The process number (MPI rank) for cluster components
step	INTEGER*4	The linear progress indicator that shows the amount of work done. Increases from 0 to the linear size of the problem during the computation.
stage	CHARACTER*(*)	Message indicating the name of the routine or the name of the computation stage the progress routine is called from.

Description

The `mkl_progress` function is intended to track progress of a lengthy computation and/or interrupt the computation. By default this routine does nothing but the user application can redefine it to obtain the computation progress information. You can set it to perform certain operations during the routine computation, for instance, to print a progress indicator. A non-zero return value may be supplied by the redefined function to break the computation.

NOTE
The user-defined `mkl_progress` function must be thread-safe.

Some Intel® oneAPI Math Kernel Library (oneMKL) functions from LAPACK, ScaLAPACK, DSS/PARDISO, and Parallel Direct Sparse Solver for Clusters regularly call the`mkl_progress` function during the computation. Refer to the description of a specific function from those domains to see whether the function supports this feature or not.

If a LAPACK function returns *info*=-1002, the function was interrupted by `mkl_progress`. Because ScaLAPACK does not support interruption of the computation, Intel® oneAPI Math Kernel Library (oneMKL) ignores any value returned by`mkl_progress`.

While a user-supplied `mkl_progress` function usually redefines the default `mkl_progress` function automatically, some configurations require calling the `mkl_set_progress` function to replace the default `mkl_progress` function. Call `mkl_set_progress` to replace the default `mkl_progress` on Windows* in any of the following cases:

- You are using the Single Dynamic Library (SDL) `mkl_rt.lib`.
- You link dynamically with ScaLAPACK.

Warning
The `mkl_progress` function supports OpenMP*/TBB threading and sequential execution for specific routines.

Return Values

Name	Type	Description
stopflag	INTEGER	The stopping flag. A non-zero flag forces the routine to be interrupted. The zero flag is the default return value.

Example

The following example prints the progress information to the standard output device:

```
integer function mkl_progress( thread_process, step, stage )
integer*4 thread_process, step
character*(*) stage
print*,'Thread:',thread_process,',stage:',stage,',step:',step
mkl_progress = 0
return
end
```

mkl_enable_instructions

Enables dispatching for new Intel® architectures or restricts the set of Intel® instruction sets available for dispatching. The `mkl_enable_instructions` function must be called only once, before any other Intel® oneAPI Math Kernel Library (oneMKL) functions.

Syntax

`irc = mkl_enable_instructions(isa)`

Input Parameters

Name	Type	Description
isa	INTEGER*4	The latest Intel® instruction-set architecture (ISA) for Intel® oneAPI Math Kernel Library (oneMKL) to dispatch. `MKL_ENABLE_AVX512` Intel® Advanced Vector Extensions 512 (Intel® AVX-512) `MKL_ENABLE_AVX512_E1` Intel® Advanced Vector Extensions 512 (Intel® AVX-512) with support for Intel® Deep Learning Boost (Intel® DL Boost). `MKL_ENABLE_AVX512_E2` Intel® Advanced Vector Extensions 512 (Intel® AVX-512) with support for Intel® Deep Learning Boost (Intel® DL

Name	Type	Description
		Boost), EVEX-encoded AES, and Carry-Less Multiplication Quadword instructions
	`MKL_ENABLE_AVX512_E3`	Intel® Advanced Vector Extensions 512 (Intel® AVX-512) with support for Intel® Deep Learning Boost (Intel® DL Boost) and bfloat16
	`MKL_ENABLE_AVX512_E4`	Intel® Advanced Vector Extensions 512 (Intel® AVX-512) with support for INT8, BF16, FP16 (limited) instructions, and Intel® Advanced Matrix Extensions (Intel® AMX) with INT8 and BF16
	`MKL_ENABLE_AVX512_E5`	Intel® Advanced Vector Extensions 512 (Intel® AVX-512) with support for INT8, BF16, FP16 (limited) instructions, and Intel® Advanced Matrix Extensions (Intel® AMX) with INT8, BF16, and FP16 **NOTE** Not dispatched by default.
	`MKL_ENABLE_AVX2`	Intel® Advanced Vector Extensions 2 (Intel® AVX2)
	`MKL_ENABLE_AVX2_E1`	Intel® Advanced Vector Extensions 2 (Intel® AVX2) with support for Intel® Deep Learning Boost (Intel® DL Boost)
	`MKL_ENABLE_SSE4_2`	Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2)

Description

Intel® oneAPI Math Kernel Library (oneMKL) does run-time processor dispatching to identify appropriate internal code paths to traverse for Intel® oneAPI Math Kernel Library (oneMKL) functions called by the application. The `mkl_enable_instructions` function controls the behavior of the dispatcher to do either of the following:

- Enable dispatching for new Intel architectures.

Intel® oneAPI Math Kernel Library (oneMKL) does not dispatch instruction sets that do not have silicon available at time of the product launch. Call`mkl_enable_instructions` to enable dispatching the code path for such an ISA in a simulator environment or on hardware that supports this ISA.

- Restrict the set of Intel instruction sets available for dispatching.

  Call `mkl_enable_instructions` to restrict dispatching to code paths for earlier ISA. For example, if the hardware supports Intel AVX, a call to `mkl_enable_instructions` with the `MKL_ENABLE_SSE4_2` parameter forces the dispatcher to use the Intel SSE4-2 code path.

If the system does not support the instruction set specified by the *isa* parameter or if the system is based on a non-Intel architecture, `mkl_enable_instructions` does nothing and returns zero.

Settings specified by the `mkl_enable_instructions` function set an upper limit to settings specified by the `mkl_cbwr_set` function.

You can use the `MKL_ENABLE_INSTRUCTIONS` environment variable instead of calling `mkl_enable_instructions` (for more details, see the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*); however, the settings specified by the function take precedence over the settings specified by the environment variable.

Return Values

Name	Type	Description
irc	INTEGER*4	Function completion status: 1 - Intel® oneAPI Math Kernel Library (oneMKL) dispatches the code path for the specified ISA by default. 0 - The request is rejected. Usually this occurs if `mkl_enable_instructions` was called: • After another Intel® oneAPI Math Kernel Library (oneMKL) function • On a non-Intel architecture • With an incompatible ISA specified

Notice revision #20201201

mkl_set_env_mode

Sets up the mode that ignores environment settings specific to Intel® oneAPI Math Kernel Library (oneMKL).

Syntax

current_mode = mkl_set_env_mode(*mode*)

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
mode	INTEGER*4	Specifies what mode to set. For details, see Description. Possible values: • 0 - Do nothing. Use this value to query the current environment mode. • 1 - Make Intel® oneAPI Math Kernel Library (oneMKL) ignore environment settings specific to the library.

Description

In the default *environment mode*, Intel® oneAPI Math Kernel Library (oneMKL) can control its behavior using environment variables for threading, memory management, Conditional Numerical Reproducibility, automatic offload, and so on. The`mkl_set_env_mode` function sets up the environment mode that ignores all settings specified by Intel® oneAPI Math Kernel Library (oneMKL) environment variables except`MIC_LD_LIBRARY_PATH` and `MKLROOT`.

Return Values

Name	Type	Description
current_mode	INTEGER*4	Environment mode that was used before the function call: • 0 - Default • 1 - Ignore environment settings specific to Intel® oneAPI Math Kernel Library (oneMKL).

mkl_verbose

Enables or disables Intel® oneAPI Math Kernel Library (oneMKL) Verbose mode.

Syntax

`status = mkl_verbose(`*enable*`)`

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
enable	INTEGER*4	Desired state of the Intel® oneAPI Math Kernel Library (oneMKL) Verbose mode. Indicates whether printing Intel® oneAPI Math Kernel Library (oneMKL) function call information should be turned on or off. Possible values: • 0 – disable the Verbose mode • 1 – enable the Verbose mode (GPU application: enable the Verbose mode without timing)

Name	Type	Description
		• 2 – enable the Verbose mode (GPU application: enable the Verbose mode with synchronous timing)

Description

This function enables or disables the Intel® oneAPI Math Kernel Library (oneMKL) Verbose mode, in which computational functions print call description information. For details of the Verbose mode, see the*Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*, available in the Intel® Software Documentation Library.

NOTE
The setting for the Verbose mode specified by the `mkl_verbose` function takes precedence over the setting specified by the `MKL_VERBOSE` environment variable.

Return Values

Name	Type	Description

status	INTEGER*4	• If the requested operation completed successfully, contains previous state of the verbose mode:
		  • 0 – Verbose mode was disabled
		  • 1 – Verbose mode was enabled (GPU application: Verbose mode was enabled without timing)
		  • 2 – Verbose mode was enabled (GPU application: Verbose mode was enabled with synchronous timing)
		• If the function failed to complete the operation because of an incorrect input parameter, equals –1.

Intel Software Documentation Library

mkl_verbose_output_file

Write output in Intel® oneAPI Math Kernel Library (oneMKL) Verbose mode to a file.

Syntax

```
mkl_verbose_output_file (filename) character *(*)
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
filename	CHARACTER	Name of file. Specify the complete path of the output file.

Description

This function writes the output in Verbose mode to the file specified in the path.

If the write operation is successful, the function returns 0.

If the file does not exist or cannot be opened, the write operation is unsuccessful. The function returns 1 and defaults to `mkl_verbose` behavior by printing to `stdout`.

NOTE
You can alternatively use MKL_VERBOSE_OUTPUT_FILE environment variable instead of calling the `mkl_verbose_output_file` function. If you want to use the environment variable option, you must set it to the complete path of the output file.

Important The setting for the verbose output file specified by the `mkl_verbose_output_file` function takes precedence over the setting specified by the MKL_VERBOSE_OUTPUT_FILE environment variable.

For more information on the Verbose mode, see the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*, available in the Intel® Software Documentation Library.

Return Values

Name	Type	Description
status	INTEGER*4	• 0 indicates that the write operation was successful. • 1 indicates that the write operation was unsuccessful.

Intel Software Documentation Library

mkl_set_mpi

Sets the implementation of the message-passing interface to be used by Intel® oneAPI Math Kernel Library (oneMKL).

Syntax

```
status = mkl_set_mpi(vendor, custom_library_name)
```

Fortran Include Files/Modules

- Include file: `mkl.fi`
- Module (compiled): `mkl_service.mod`
- Module (source): `mkl_service.f90`

Input Parameters

Name	Type	Description
vendor	INTEGER*4	Specifies the implementation of the message-passing interface (MPI) to use: Possible values:

Name	Type	Description
		• MKL_BLACS_CUSTOM - a custom MPI library. Requires a prebuilt custom MPI BLACS library. • MKL_BLACS_MSMPI - Microsoft MPI library. • MKL_BLACS_INTELMPI - Intel® MPI library. • MKL_BLACS_MPICH - MPICH MPI library.
custom_library_name	CHARACTER*	The filename (without a directory name) of the custom BLACS dynamic library to use. This library must be located in the directory with your application executable or with Intel® oneAPI Math Kernel Library (oneMKL) dynamic libraries. Can be NULL or an empty string.
vendor		

Description

Call this function to set the MPI implementation to be used by Intel® oneAPI Math Kernel Library (oneMKL) on Windows* OS when dynamic Intel® oneAPI Math Kernel Library (oneMKL) libraries are used. For all other configurations, the function returns an error indicating that you cannot set the MPI implementation. You can specify your own prebuilt dynamic BLACS library for a custom MPI by setting *vendor* to MKL_BLACS_CUSTOM and optionally passing the name of the custom BLACS dynamic library. If the *custom_library_path* parameter is *NULL* or an empty string, Intel® oneAPI Math Kernel Library (oneMKL) uses the default platform-specific library name: mkl_blacs_custom_lp64.dll or mkl_blacs_custom_ilp64.dll, depending on whether the BLACS interface linked against your application is LP64 or ILP64.

Return Values

Name	Type	Description
status	INTEGER*4	The return status: • 0 - The function completed successfully. • -1 - The *vendor* parameter is invalid. • -2 - The *custom_library_name* parameter is invalid. • -3 - The MPI library cannot be set at this point.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

mkl_finalize

Terminates Intel® oneAPI Math Kernel Library (oneMKL) execution environment and frees resources allocated by the library.

Syntax

```
call mkl_finalize
```

Fortran Include Files/Modules

- Include file: mkl.fi
- Module (compiled): mkl_service.mod

- Module (source): `mkl_service.f90`

Description

This function frees resources allocated by Intel® oneAPI Math Kernel Library (oneMKL). Once this function is called, the application can no longer call Intel® oneAPI Math Kernel Library (oneMKL) functions other than`mkl_finalize`.

In particular, the `mkl_finalize`function enables you to free resources when a third-party shared library is statically linked to Intel® oneAPI Math Kernel Library (oneMKL). To avoid resource leaks that may happen when a shared library is loaded and unloaded multiple times, call`mkl_finalize` each time the library is unloaded. The recommended method to do this depends on the operating system:

- On Linux* or macOS*, place the call into a shared library destructor.
- On Windows*, call `mkl_finalize` from the `DLL_PROCESS_DETACH` handler of `DllMain`.

> **NOTE**
> Intel® oneAPI Math Kernel Library (oneMKL) shared libraries automatically perform finalization when they are unloaded. If an application is statically linked to Intel® oneAPI Math Kernel Library (oneMKL), the operating system frees all resources allocated by Intel® oneAPI Math Kernel Library (oneMKL) during termination of the process associated with the application.

BLACS Routines

Intel® oneAPI Math Kernel Libraryimplements FORTRAN 77 routines from the BLACS (Basic Linear Algebra Communication Subprograms) package. These routines are used to support a linear algebra oriented message passing interface that may be implemented efficiently and uniformly across a large range of distributed memory platforms.

The BLACS routines make linear algebra applications both easier to program and more portable. For this purpose, they are used in Intel® oneAPI Math Kernel Library (oneMKL) intended for the Linux* and Windows* OSs as the communication layer of ScaLAPACK and Cluster FFT.

On computers, a linear algebra matrix is represented by a two dimensional array (2D array), and therefore the BLACS operate on 2D arrays. See description of the basic matrix shapes in a special topic.

The BLACS routines implemented in Intel® oneAPI Math Kernel Library (oneMKL) are of four categories:

- Combines
- Point to Point Communication
- Broadcast
- Support.

The Combines take data distributed over processes and combine the data to produce a result. The Point to Point routines are intended for point-to-point communication and Broadcast routines send data possessed by one process to all processes within a scope.

The Support routines perform distinct tasks that can be used for initialization, destruction, information, and miscellaneous tasks.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Matrix Shapes

The BLACS routines recognize the two most common classes of matrices for dense linear algebra. The first of these classes consists of general rectangular matrices, which in machine storage are 2D arrays consisting of *m* rows and *n* columns, with a leading dimension, *lda*, that determines the distance between successive columns in memory.

The *general rectangular* matrices take the following parameters as input when determining what array to operate on:

m	(input) INTEGER. The number of matrix rows to be operated on.
n	(input) INTEGER. The number of matrix columns to be operated on.
a	(input/output) TYPE (depends on routine), array of dimension (*lda*,*n*). A pointer to the beginning of the (sub)array to be sent.
lda	(input) INTEGER. The distance between two elements in matrix row.

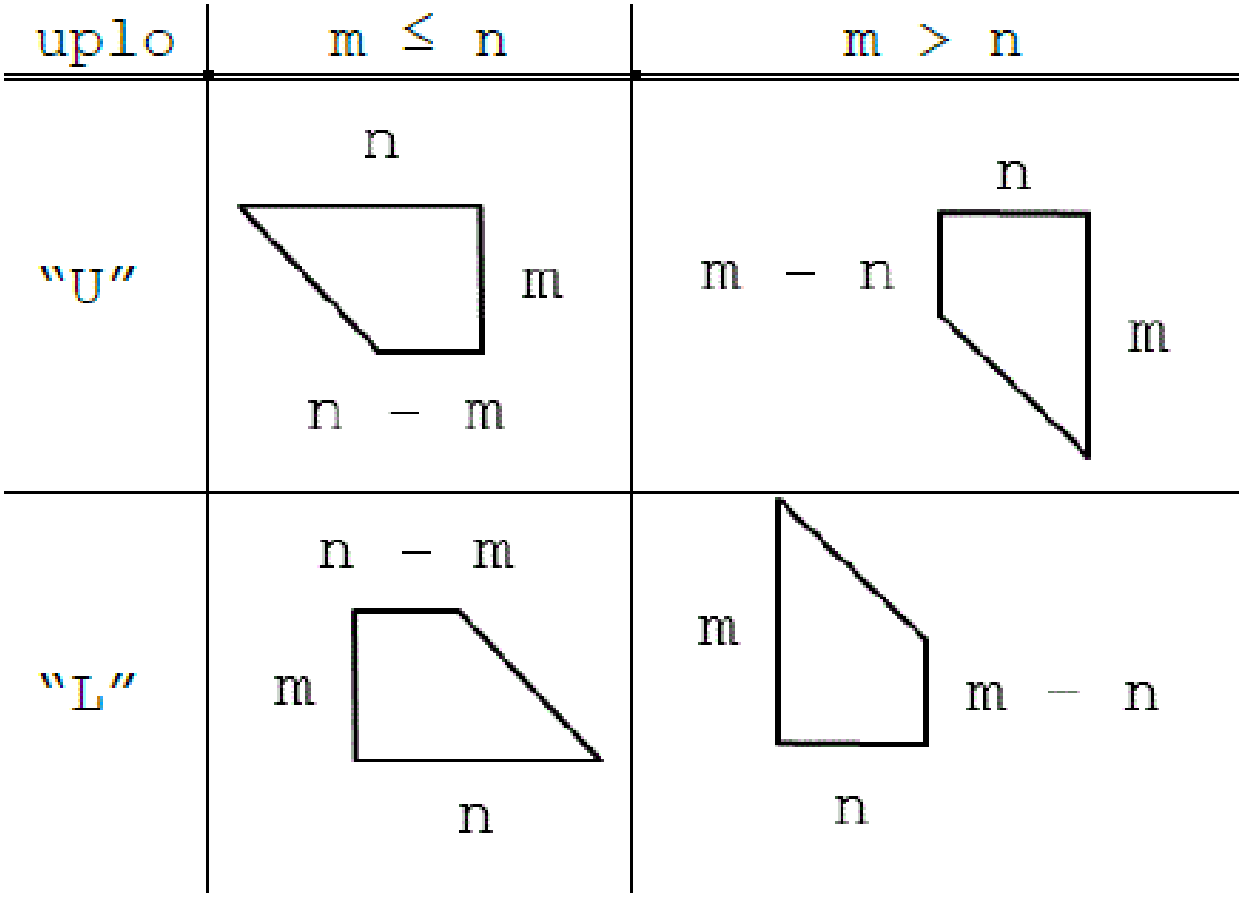
The second class of matrices recognized by the BLACS are *trapezoidal* matrices (triangular matrices are a sub-class of trapezoidal). Trapezoidal arrays are defined by *m*, *n*, and *lda*, as above, but they have two additional parameters as well. These parameters are:

uplo	(input) CHARACTER*1 . Indicates whether the matrix is upper or lower trapezoidal, as discussed below.
diag	(input) CHARACTER*1 . Indicates whether the diagonal of the matrix is unit diagonal (will not be operated on) or otherwise (will be operated on).

The shape of the trapezoidal arrays is determined by these parameters as follows:

__border__top

Trapezoidal Arrays Shapes



The packing of arrays, if required, so that they may be sent efficiently is hidden, allowing the user to concentrate on the logical matrix, rather than on how the data is organized in the system memory.

Repeatability and Coherence

Floating point computations are not exact on almost all modern architectures. This lack of precision is particularly problematic in parallel operations. Since floating point computations are inexact, algorithms are classified according to whether they are *repeatable* and to what degree they guarantee *coherence*.

- Repeatable: a routine is repeatable if it is guaranteed to give the same answer if called multiple times with the same parallel configuration and input.
- Coherent: a routine is coherent if all processes selected to receive the answer get identical results.

> **NOTE**
> Repeatability and coherence do not effect correctness. A routine may be both incoherent and non-repeatable, and still give correct output. But inaccuracies in floating point calculations may cause the routine to return differing values, all of which are equally valid.

Repeatability

Because the precision of floating point arithmetic is limited, it is not truly associative: `(a + b) + c` might not be the same as `a + (b + c)`. The lack of exact arithmetic can cause problems whenever the possibility for reordering of floating point calculations exists. This problem becomes prevalent in parallel computing due to race conditions in message passing. For example, consider a routine which sums numbers stored on different processes. Assume this routine runs on four processes, with the numbers to be added being the process numbers themselves. Therefore, process 0 has the value 0:0, process 1 has the value 1:0, and son on.

One algorithm for the computation of this result is to have all processes send their process numbers to process 0; process 0 adds them up, and sends the result back to all processes. So, process 0 would add a number to 0:0 in the first step. If receiving the process numbers is ordered so that process 0 always receives the message from process 1 first, then 2, and finally 3, this results in a repeatable algorithm, which evaluates the expression `((0:0+ 1:0) + 2:0) + 3:0`.

However, to get the best parallel performance, it is better not to require a particular ordering, and just have process 0 add the first available number to its value and continue to do so until all numbers have been added in. Using this method, a race condition occurs, because the order of the operation is determined by the order in which process 0 receives the messages, which can be effected by any number of things. This implementation is not repeatable, because the answer can vary between invocations, even if the input is the same. For instance, one run might produce the sequence `((0:0+1:0)+2:0)+3:0`, while a subsequent run could produce `((0:0 + 2:0) + 1:0) + 3:0`. Both of these results are correct summations of the given numbers, but because of floating point roundoff, they might be different.

Coherence

A routine produces coherent output if all processes are guaranteed to produce the exact same results. Obviously, almost no algorithm involving communication is coherent if communication can change the values being communicated. Therefore, if the parallel system being studied cannot guarantee that communication between processes preserves values, no routine is guaranteed to produce coherent results.

If communication is assumed to be coherent, there are still various levels of coherent algorithms. Some algorithms guarantee coherence only if floating point operations are done in the exact same order on every node. This is *homogeneous coherence*: the result will be coherent if the parallel machine is homogeneous in its handling of floating point operations.

A stronger assertion of coherence is *heterogeneous coherence*, which does not require all processes to have the same handling of floating point operations.

In general, a routine that is homogeneous coherent performs computations redundantly on all nodes, so that all processes get the same answer only if all processes perform arithmetic in the exact same way, whereas a routine which is heterogeneous coherent is usually constrained to having one process calculate the final result, and broadcast it to all other processes.

Example of Incoherence

An incoherent algorithm is one which does not guarantee that all processes get the same result even on a homogeneous system with coherent communication. The previous example of summing the process numbers demonstrates this kind of behavior. One way to perform such a sum is to have every process broadcast its number to all other processes. Each process then adds these numbers, starting with its own. The calculations performed by each process receives would then be:

- Process 0 : `((0:0+ 1:0) + 2:0) + 3:0`
- Process 1 : `((1:0+ 2:0) + 3:0) + 0:0`
- Process 2 : `((2:0+ 3:0) + 0:0) + 1:0`
- Process 3 : `((3:0+ 0:0) + 1:0) + 0:0`

All of these results are equally valid, and since all the results might be different from each other, this algorithm is incoherent. Notice, however, that this algorithm is repeatable: each process will get the same result if the algorithm is called again on the same data.

Example of Homogeneous Coherence

Another way to perform this summation is for all processes to send their data to all other processes, and to ensure the result is not incoherent, enforce the ordering so that the calculation each node performs is `((0:0+ 1:0) + 2:0) + 3:0`. This answer is the same for all processes only if all processes do the floating point arithmetic in the same way. Otherwise, each process may make different floating point errors during the addition, leading to incoherence of the output. Notice that since there is a specific ordering to the addition, this algorithm is repeatable.

Example of Heterogeneous Coherence

In the final example, all processes send the result to process 0, which adds the numbers and broadcasts the result to the rest of the processes. Since one process does all the computation, it can perform the operations in any order and it will give coherent results as long as communication is itself coherent. If a particular order is not forced on the the addition, the algorithm will not be repeatable. If a particular order is forced, it will be repeatable.

Summary

Repeatability and coherence are separate issues which may occur in parallel computations. These concepts may be summarized as:

- Repeatability: The routine will yield the exact same result if it run multiple times on an identical problem. Each process may get a different result than the others (i.e., repeatability does not imply coherence), but that value will not change if the routine is invoked multiple times.
- Homogeneous coherence: All processes selected to possess the result will receive the exact same answer if:
  - Communication does not change the value of the communicated data.
  - All processes perform floating point arithmetic exactly the same.
- Heterogeneous coherence: All processes will receive the exact same answer if communication does not change the value of the communicated data.

In general, lack of the associative property for floating point calculations may cause both incoherence and non-repeatability. Algorithms that rely on redundant computations are at best homogeneous coherent, and algorithms in which one process broadcasts the result are heterogeneous coherent. Repeatability does not imply coherence, nor does coherence imply repeatability.

Since these issues do not effect the correctness of the answer, they can usually be ignored. However, in very specific situations, these issues may become very important. A stopping criteria should not be based on incoherent results, for instance. Also, a user creating and debugging a parallel program may wish to enforce repeatability so the exact same program sequence occurs on every run.

In the BLACS, coherence and repeatability apply only in the context of the combine operations. As mentioned above, it is possible to have communication which is incoherent (for instance, two machines which store floating point numbers differently may easily produce incoherent communication, since a number stored on machine A may not have a representation on machine B). However, the BLACS cannot control this issue. Communication is assumed to be coherent, which for communication implies that it is also repeatable.

For combine operations, the BLACS allow you to set flags indicating that you would like combines to be repeatable and/or heterogeneous coherent (see `blacs_get` and `blacs_set` for details on setting these flags).

If the BLACS are instructed to guarantee heterogeneous coherency, the BLACS restrict the topologies which can be used so that one process calculates the final result of the combine, and if necessary, broadcasts the answer to all other processes.

If the BLACS are instructed to guarantee repeatability, orderings will be enforced in the topologies which are selected. This may result in loss of performance which can range from negligible to serious depending on the application.

A couple of additional notes are in order. Incoherence and nonrepeatability can arise as a result of floating point errors, as discussed previously. This might lead you to suspect that integer calculations are always repeatable and coherent, since they involve exact arithmetic. This is true if overflow is ignored. With overflow taken into consideration, even integer calculations can display incoherence and non-repeatability. Therefore, if the repeatability or coherence flags are set, the BLACS treats integer combines the same as floating point combines in enforcing repeatability and coherence guards.

By their nature, maximization and minimization should always be repeatable. In the complex precisions, however, the real and imaginary parts must be combined in order to obtain a magnitude value used to do the comparison (this is typically $|r| + |i|$ or $\mathrm{sqr}(r^2 + i^2)$). This allows for the possibility of heterogeneous incoherence. The BLACS therefore restrict which topologies are used for maximization and minimization in the complex routines when the heterogeneous coherence flag is set.

BLACS Combine Operations

This topic describes BLACS routines that combine the data to produce a result.

In a combine operation, each participating process contributes data that is combined with other processes' data to produce a result. This result can be given to a particular process (called the *destination* process), or to all participating processes. If the result is given to only one process, the operation is referred to as a *leave-on-one* combine, and if the result is given to all participating processes the operation is referenced as a *leave-on-all* combine.

At present, three kinds of combines are supported. They are:

- element-wise summation
- element-wise absolute value maximization
- element-wise absolute value minimization

of general rectangular arrays.

Note that a combine operation combines data between processes. By definition, a combine performed across a scope of only one process does not change the input data. This is why the operations (`max`/`min`/`sum`) are specified as *element-wise*. Element-wise indicates that each element of the input array will be combined with the corresponding element from all other processes' arrays to produce the result. Thus, a 4 x 2 array of inputs produces a 4 x 2 answer array.

When the `max`/`min` comparison is being performed, absolute value is used. For example, -5 and 5 are equivalent. However, the returned value is unchanged; that is, it is not the absolute value, but is a signed value instead. Therefore, if you performed a BLACS absolute value maximum combine on the numbers -5, 3, 1, 8 the result would be -8.

The initial symbol `?` in the routine names below masks the data type:

`i`	integer
`s`	single precision real
`d`	double precision real
`c`	single precision complex
`z`	double precision complex.

BLACS Combines

Routine name	Results of operation
gamx2d	Entries of result matrix will have the value of the greatest absolute value found in that position.
gamn2d	Entries of result matrix will have the value of the smallest absolute value found in that position.
gsum2d	Entries of result matrix will have the summation of that position.

?gamx2d

Performs element-wise absolute value maximization.

Syntax

```
call igamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call sgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call dgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call cgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call zgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
```

Input Parameters

icontxt — INTEGER. Integer handle that indicates the context.

scope — CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.

top — CHARACTER*1. Communication pattern to use during the combine operation.

m — INTEGER. The number of matrix rows to be combined.

n — INTEGER. The number of matrix columns to be combined.

a — TYPE array (*lda*, *n*). Matrix to be compared with to produce the maximum.

lda — INTEGER. The leading dimension of the matrix *A*, that is, the distance between two successive elements in a matrix row.

rcflag — INTEGER.

If *rcflag* = -1, the arrays *ra* and *ca* are not referenced and need not exist. Otherwise, *rcflag* indicates the leading dimension of these arrays, and so must be ≥ *m*.

rdest — INTEGER.

The process row coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

cdest — INTEGER.

The process column coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

Output Parameters

a — TYPE array (*lda*, *n*). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.

ra — INTEGER array (*rcflag*, *n*).

If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* x *n*) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

ca — INTEGER array (*rcflag*, *n*).

If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* x *n*) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value maximization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the maximum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

Examples of BLACS Routines Usage

?gamn2d

Performs element-wise absolute value minimization.

Syntax

```
call igamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call sgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call dgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call cgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call zgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
```

Input Parameters

icontxt — INTEGER. Integer handle that indicates the context.

scope — CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.

top CHARACTER*1. Communication pattern to use during the combine operation.

m INTEGER. The number of matrix rows to be combined.

n INTEGER. The number of matrix columns to be combined.

a TYPE array (*lda*, *n*). Matrix to be compared with to produce the minimum.

lda INTEGER. The leading dimension of the matrix *A*, that is, the distance between two successive elements in a matrix row.

rcflag INTEGER.

If *rcflag* = -1, the arrays *ra* and *ca* are not referenced and need not exist. Otherwise, *rcflag* indicates the leading dimension of these arrays, and so must be ≥ *m*.

rdest INTEGER.

The process row coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

cdest INTEGER.

The process column coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

Output Parameters

a TYPE array (*lda*, *n*). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.

ra INTEGER array (*rcflag*, *n*).

If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* x *n*) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

ca INTEGER array (*rcflag*, *n*).

If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* x *n*) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value minimization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the minimum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

Examples of BLACS Routines Usage

?gsum2d

Performs element-wise summation.

Syntax

```
call igsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call sgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call dgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call cgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call zgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
top	CHARACTER*1. Communication pattern to use during the combine operation.
m	INTEGER. The number of matrix rows to be combined.
n	INTEGER. The number of matrix columns to be combined.
a	TYPE array (*lda*, *n*). Matrix to be added to produce the sum.
lda	INTEGER. The leading dimension of the matrix *A*, that is, the distance between two successive elements in a matrix row.
rdest	INTEGER. The process row coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.
cdest	INTEGER. The process column coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

Output Parameters

a	TYPE array (*lda*, *n*). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.

Description

This routine performs element-wise summation, that is, each element of matrix *A* is summed with the corresponding element of the other process's matrices. Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

BLACS Point To Point Communication

This topic describes BLACS routines for point to point communication.

Point to point communication requires two complementary operations. The *send* operation produces a message that is then consumed by the *receive* operation. These operations have various resources associated with them. The main such resource is the buffer that holds the data to be sent or serves as the area where the incoming data is to be received. The level of *blocking* indicates what correlation the return from a send/receive operation has with the availability of these resources and with the status of message.

Non-blocking

The return from the *send* or *receive* operations does not imply that the resources may be reused, that the message has been sent/received or that the complementary operation has been called. Return means only that the send/receive has been started, and will be completed at some later date. Polling is required to determine when the operation has finished.

In non-blocking message passing, the concept of *communication/computation overlap* (abbreviated C/C overlap) is important. If a system possesses C/C overlap, independent computation can occur at the same time as communication. That means a nonblocking operation can be posted, and unrelated work can be done while the message is sent/received in parallel. If C/C overlap is not present, after returning from the routine call, computation will be interrupted at some later date when the message is actually sent or received.

Locally-blocking

Return from the *send* or *receive* operations indicates that the resources may be reused. However, since this only depends on local information, it is unknown whether the complementary operation has been called. There are no locally-blocking receives: the send must be completed before the receive buffer is available for re-use.

If a receive has not been posted at the time a locally-blocking send is issued, buffering will be required to avoid losing the message. Buffering can be done on the sending process, the receiving process, or not done at all, losing the message.

Globally-blocking

Return from a globally-blocking procedure indicates that the operation resources may be reused, and that complement of the operation has at least been posted. Since the receive has been posted, there is no buffering required for globally-blocking sends: the message is always sent directly into the user's receive buffer.

Almost all processors support non-blocking communication, as well as some other level of blocking sends. What level of blocking the send possesses varies between platforms. For instance, the Intel® processors support locally-blocking sends, with buffering done on the receiving process. This is a very important distinction, because codes written assuming locally-blocking sends will hang on platforms with globally-blocking sends. Below is a simple example of how this can occur:

```
IAM = MY_PROCESS_ID()
 IF (IAM .EQ. 0) THEN
   SEND TO PROCESS 1
   RECV FROM PROCESS 1
ELSE IF (IAM .EQ. 1) THEN
   SEND TO PROCESS 0
   RECV FROM PROCESS 0
END IF
```

If the send is globally-blocking, process 0 enters the send, and waits for process 1 to start its receive before continuing. In the meantime, process 1 starts to send to 0, and waits for 0 to receive before continuing. Both processes are now waiting on each other, and the program will never continue.

The solution for this case is obvious. One of the processes simply reverses the order of its communication calls and the hang is avoided. However, when the communication is not just between two processes, but rather involves a hierarchy of processes, determining how to avoid this kind of difficulty can become problematic.

For this reason, it was decided the BLACS would support locally-blocking sends. On systems natively supporting globally-blocking sends, non-blocking sends coupled with buffering is used to simulate locally-blocking sends. The BLACS support globally-blocking receives.

In addition, the BLACS specify that point to point messages between two given processes will be strictly ordered. If process 0 sends three messages (label them *A*, *B*, and *C*) to process 1, process 1 must receive *A* before it can receive *B*, and message *C* can be received only after both *A* and *B*. The main reason for this restriction is that it allows for the computation of message identifiers.

Note, however, that messages from different processes are not ordered. If processes 0, . . ., 3 send messages *A*, . . ., *D* to process 4, process 4 may receive these messages in any order that is convenient.

Convention

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

`i`	integer
`s`	single precision real
`d`	double precision real
`c`	single precision complex
`z`	double precision complex
`ge`	The data to be communicated is stored in a general rectangular matrix.
`tr`	The data to be communicated is stored in a trapezoidal matrix.
`sd`	Send. One process sends to another.
`rv`	Receive. One process receives from another.

BLACS Point To Point Communication

Routine name	Operation performed
gesd2d trsd2d	Take the indicated matrix and send it to the destination process.
gerv2d trrv2d	Receive a message from the process into the matrix.

As a simple example, the pseudo code given above is rewritten below in terms of the BLACS. It is further specifed that the data being exchanged is the double precision vector *X*, which is 5 elements long.

```
CALL GRIDINFO(NPROW, NPCOL, MYPROW, MYPCOL)

IF (MYPROW.EQ.0 .AND. MYPCOL.EQ.0) THEN
   CALL DGESD2D(5, 1, X, 5, 1, 0)
   CALL DGERV2D(5, 1, X, 5, 1, 0)
ELSE IF (MYPROW.EQ.1 .AND. MYPCOL.EQ.0) THEN
   CALL DGESD2D(5, 1, X, 5, 0, 0)
   CALL DGERV2D(5, 1, X, 5, 0, 0)
END IF
```

?gesd2d

Takes a general rectangular matrix and sends it to the destination process.

Syntax

```
call igesd2d( icontxt, m, n, a, lda, rdest, cdest )
call sgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call dgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call cgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call zgesd2d( icontxt, m, n, a, lda, rdest, cdest )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
m, *n*, *a*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.
rdest	INTEGER. The process row coordinate of the process to send the message to.
cdest	INTEGER. The process column coordinate of the process to send the message to.

Description

This routine takes the indicated general rectangular matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix *A*) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

See Also

Examples of BLACS Routines Usage

?trsd2d

Takes a trapezoidal matrix and sends it to the destination process.

Syntax

```
call itrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call strsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call dtrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ctrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ztrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
uplo, *diag*, *m*, *n*, *a*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.
rdest	INTEGER. The process row coordinate of the process to send the message to.
cdest	INTEGER. The process column coordinate of the process to send the message to.

Description

This routine takes the indicated trapezoidal matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix *A*) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

?gerv2d

Receives a message from the process into the general rectangular matrix.

Syntax

```
call igerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call sgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call dgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call cgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call zgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
m, *n*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.
rsrc	INTEGER. The process row coordinate of the source of the message.

csrc	INTEGER. The process column coordinate of the source of the message.

Output Parameters

a	An array of dimension (*lda*,*n*) to receive the incoming message into.

Description

This routine receives a message from process {RSRC, CSRC} into the general rectangular matrix *A*. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into *A*.

See Also

Examples of BLACS Routines Usage

?trrv2d

Receives a message from the process into the trapezoidal matrix.

Syntax

```
call itrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call strrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
uplo, *diag*, *m*, *n*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.
rsrc	INTEGER. The process row coordinate of the source of the message.
csrc	INTEGER. The process column coordinate of the source of the message.

Output Parameters

a	An array of dimension (*lda*,*n*) to receive the incoming message into.

Description

This routine receives a message from process {RSRC, CSRC} into the trapezoidal matrix *A*. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into *A*.

BLACS Broadcast Routines

This topic describes BLACS broadcast routines.

A broadcast sends data possessed by one process to all processes within a scope. Broadcast, much like point to point communication, has two complementary operations. The process that owns the data to be broadcast issues a *broadcast*/*send*. All processes within the same scope must then issue the complementary *broadcast*/*receive*.

The BLACS define that both broadcast/send and broadcast/receive are *globally-blocking*. Broadcasts/receives cannot be locally-blocking since they must post a receive. Note that receives cannot be locally-blocking. When a given process can leave, a broadcast/receive operation is topology dependent, so, to avoid a hang as topology is varied, the broadcast/receive must be treated as if no process can leave until all processes have called the operation.

Broadcast/sends could be defined to be *locally-blocking*. Since no information is being received, as long as locally-blocking point to point sends are used, the broadcast/send will be locally blocking. However, defining one process within a scope to be locally-blocking while all other processes are globally-blocking adds little to the programmability of the code. On the other hand, leaving the option open to have globally-blocking broadcast/sends may allow for optimization on some platforms.

The fact that broadcasts are defined as globally-blocking has several important implications. The first is that scoped operations (broadcasts or combines) must be strictly ordered, that is, all processes within a scope must agree on the order of calls to separate scoped operations. This constraint falls in line with that already in place for the computation of message IDs, and is present in point to point communication as well.

A less obvious result is that scoped operations with `SCOPE = 'ALL'` must be ordered with respect to any other scoped operation. This means that if there are two broadcasts to be done, one along a column, and one involving the entire process grid, all processes within the process column issuing the column broadcast must agree on which broadcast will be performed first.

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

`i`	integer
`s`	single precision real
`d`	double precision real
`c`	single precision complex
`z`	double precision complex
`ge`	The data to be communicated is stored in a general rectangular matrix.
`tr`	The data to be communicated is stored in a trapezoidal matrix.
`bs`	Broadcast/send. A process begins the broadcast of data within a scope.
`br`	Broadcast/receive A process receives and participates in the broadcast of data within a scope.

BLACS Broadcast Routines

Routine name	Operation performed
gebs2d trbs2d	Start a broadcast along a scope.
gebr2d trbr2d	Receive and participate in a broadcast along a scope.

Product and Performance Information
Notice revision #20201201

?gebs2d

Starts a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebs2d( icontxt, scope, top, m, n, a, lda )
call sgebs2d( icontxt, scope, top, m, n, a, lda )
call dgebs2d( icontxt, scope, top, m, n, a, lda )
call cgebs2d( icontxt, scope, top, m, n, a, lda )
call zgebs2d( icontxt, scope, top, m, n, a, lda )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
top	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
m, *n*, *a*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

See Also

Examples of BLACS Routines Usage

?trbs2d

Starts a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call strbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call dtrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ctrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ztrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
top	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
uplo, *diag*, *m*, *n*, *a*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

?gebr2d

Receives and participates in a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call sgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call dgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call cgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call zgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
top	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
m, *n*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.
rsrc	INTEGER. The process row coordinate of the process that called broadcast/send.
csrc	INTEGER. The process column coordinate of the process that called broadcast/send.

Output Parameters

a	An array of dimension (*lda*,*n*) to receive the incoming message into.

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

See Also

Examples of BLACS Routines Usage

?trbr2d

Receives and participates in a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call strbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
top	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
uplo, *diag*, *m*, *n*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.
rsrc	INTEGER. The process row coordinate of the process that called broadcast/send.
csrc	INTEGER. The process column coordinate of the process that called broadcast/send.

Output Parameters

a	An array of dimension (*lda*,*n*) to receive the incoming message into.

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

BLACS Support Routines

The support routines perform distinct tasks that can be used for:

Initialization

Destruction

Information Purposes

Miscellaneous Tasks.

Initialization Routines

This topic describes BLACS routines that deal with grid/context creation, and processing before the grid/context has been defined.

BLACS Initialization Routines

Routine name	Operation performed
blacs_pinfo	Returns the number of processes available for use.
blacs_setup	Allocates virtual machine and spawns processes.
blacs_get	Gets values that BLACS use for internal defaults.
blacs_set	Sets values that BLACS use for internal defaults.
blacs_gridinit	Assigns available processes into BLACS process grid.
blacs_gridmap	Maps available processes into BLACS process grid.

blacs_pinfo

Returns the number of processes available for use.

Syntax

```
call blacs_pinfo( mypnum, nprocs )
```

Output Parameters

mypnum	INTEGER. An integer between 0 and (*nprocs* - 1) that uniquely identifies each process.
nprocs	INTEGER.The number of processes available for BLACS use.

Description

This routine is used when some initial system information is required before the BLACS are set up. On all platforms except PVM, *nprocs* is the actual number of processes available for use, that is, *nprows * npcols <= nprocs*. In PVM, the virtual machine may not have been set up before this call, and therefore no parallel machine exists. In this case, *nprocs* is returned as less than one. If a process has been spawned via the keyboard, it receives *mypnum* of 0, and all other processes get *mypnum* of -1. As a result, the user can distinguish between processes. Only after the virtual machine has been set up via a call to BLACS_SETUP, this routine returns the correct values for *mypnum* and *nprocs*.

See Also

Examples of BLACS Routines Usage

blacs_setup

Allocates virtual machine and spawns processes.

Syntax

```
call blacs_setup( mypnum, nprocs )
```

Input Parameters

nprocs	INTEGER. On the process spawned from the keyboard rather than from pvmspawn, this parameter indicates the number of processes to create when building the virtual machine.

Output Parameters

mypnum	INTEGER. An integer between 0 and (*nprocs* - 1) that uniquely identifies each process.
nprocs	INTEGER. For all processes other than spawned from the keyboard, this parameter means the number of processes available for BLACS use.

Description

This routine only accomplishes meaningful work in the PVM BLACS. On all other platforms, it is functionally equivalent to blacs_pinfo. The BLACS assume a static system, that is, the given number of processes does not change. PVM supplies a dynamic system, allowing processes to be added to the system on the fly.

blacs_setup is used to allocate the virtual machine and spawn off processes. It reads in a file called blacs_setup.dat, in which the first line must be the name of your executable. The second line is optional, but if it exists, it should be a PVM spawn flag. Legal values at this time are 0 (PvmTaskDefault), 4 (PvmTaskDebug), 8 (PvmTaskTrace), and 12 (PvmTaskDebug + PvmTaskTrace). The primary reason for this line is to allow the user to easily turn on and off PVM debugging. Additional lines, if any, specify what machines should be added to the current configuration before spawning *nprocs*-1 processes to the machines in a round robin fashion.

nprocs is input on the process which has no PVM parent (that is, *mypnum*=0), and both parameters are output for all processes. So, on PVM systems, the call to blacs_pinfo informs you that the virtual machine has not been set up, and a call to blacs_setup then sets up the machine and returns the real values for *mypnum* and *nprocs*.

Note that if the file blacs_setup.dat does not exist, the BLACS prompt the user for the executable name, and processes are spawned to the current PVM configuration.

Examples of BLACS Routines Usage

blacs_get

Gets values that BLACS use for internal defaults.

Syntax

```
call blacs_get( icontxt, what, val )
```

Input Parameters

icontxt — INTEGER. On values of *what* that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.

what — INTEGER. Indicates what BLACS internal(s) should be returned in *val*. Present options are:

- *what* = 0 : Handle indicating default system context.
- *what* = 1 : The BLACS message ID range.
- *what* = 2 : The BLACS debug level the library was compiled with.
- *what* = 10 : Handle indicating the system context used to define the BLACS context whose handle is *icontxt*.
- *what* = 11 : Number of rings multiring broadcast topology is presently using.
- *what* = 12 : Number of branches general tree broadcast topology is presently using.
- *what* = 13 : Number of rings multiring combine topology is presently using.
- *what* = 14 : Number of branches general tree combine topology is presently using.
- *what* = 15 : Whether topologies are forced to be repeatable or not. A non-zero return value indicates that topologies are being forced to be repeatable. See Repeatability and Coherence for more information about repeatability.
- *what* = 16 : Whether topologies are forced to be heterogenous coherent or not. A non-zero return value indicates that topologies are being forced to be heterogenous coherent. See Repeatability and Coherence for more information about coherence.

Output Parameters

val — INTEGER. The value of the BLACS internal.

Description

This routine gets the values that the BLACS are using for internal defaults. Some values are tied to a BLACS context, and some are more general. The most common use is in retrieving a default system context for input into `blacs_gridinit` or `blacs_gridmap`.

Some systems, such as MPI*, supply their own version of context. For those users who mix system code with BLACS code, a BLACS context should be formed in reference to a system context. Thus, the grid creation routines take a system context as input. If you wish to have strictly portable code, you may use `blacs_get` to retrieve a default system context that will include all available processes. This value is not tied to a BLACS context, so the parameter *icontxt* is unused.

`blacs_get` returns information on three quantities that are tied to an individual BLACS context, which is passed in as *icontxt*. The information that may be retrieved is:

- The handle of the system context upon which this BLACS context was defined
- The number of rings for `TOP = 'M'` (multiring broadcast/combine)
- The number of branches for `TOP = 'T'` (general tree broadcast/general tree gather).
- Whether topologies are being forced to be repeatable or heterogenous coherent.

See Also

Examples of BLACS Routines Usage

blacs_set

Sets values that BLACS use for internal defaults.

Syntax

```
call blacs_set( icontxt, what, val )
```

Input Parameters

icontxt

INTEGER. For values of *what* that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.

what

INTEGER. Indicates what BLACS internal(s) should be set. Present values are:

- 1 = Set the BLACS message ID range
- 11 = Number of rings for multiring broadcast topology to use
- 12 = Number of branches for general tree broadcast topology to use
- 13 = Number of rings for multiring combine topology to use
- 14 = Number of branches for general tree combine topology to use
- 15 = Force topologies to be repeatable or not
- 16 = Force topologies to be heterogenous coherent or not

val

INTEGER. Array of dimension (*). Indicates the value(s) the internals should be set to. The specific meanings depend on *what* values, as discussed in Description below.

Description

This routine sets the BLACS internal defaults depending on *what* values:

what = 1

Setting the BLACS message ID range.

If you wish to mix the BLACS with other message-passing packages, restrict the BLACS to a certain message ID range not to be used by the non-BLACS routines. The message ID range must be set before the first call to blacs_gridinit or blacs_gridmap. Subsequent calls will have no effect. Because the message ID range is not tied to a particular context, the parameter *icontxt* is ignored, and *val* is defined as:

VAL (input) INTEGER array of dimension (2)

VAL(1) : The smallest message ID (also called message type or message tag) the BLACS should use.

VAL(2) : The largest message ID (also called message type or message tag) the BLACS should use.

what = 11

Set number of rings for TOP = 'M' (multiring broadcast).This quantity is tied to a context, so *icontxt* is used, and *val* is defined as:

VAL (input) INTEGER array of dimension (1)

VAL(1) : The number of rings for multiring topology to use.

what = 12
Set number of branches for `TOP = 'T'` (general tree broadcast). This quantity is tied to a context, so *icontxt* is used, and *val* is defined as:

`VAL (input) INTEGER` array of dimension (1)

`VAL(1)` : The number of branches for general tree topology to use.

what = 13
Set number of rings for `TOP = 'M'` (multiring combine).This quantity is tied to a context, so *icontxt* is used, and *val* is defined as:

`VAL (input) INTEGER` array of dimension (1)

`VAL(1)` : The number of rings for multiring topology to use.

what = 14
Set number of branches for `TOP = 'T'` (general tree gather). This quantity is tied to a context, so *icontxt* is used, and *val* is defined as:

`VAL (input) INTEGER` array of dimension (1)

`VAL(1)` : The number of branches for general tree topology to use.

what = 15
Force topologies to be repeatable or not (see Repeatability and Coherence for more information about repeatability).

`VAL (input) INTEGER` array of dimension (1)

`VAL(1) = 0` (default)	Topologies are not required to be repeatable.
`VAL(1) ≠ 0`	All used topologies are required to be repeatable, which might degrade performance.

what = 16
Force topologies to be heterogenous coherent or not (see Repeatability and Coherence for more information about coherence).

`VAL (input) INTEGER` array of dimension (1)

`VAL(1) = 0` (default)	Topologies are not required to be heterogenous coherent.
`VAL(1) ≠ 0`	All used topologies are required to be heterogenous coherent, which might degrade performance.

blacs_gridinit

Assigns available processes into BLACS process grid.

Syntax

```
call blacs_gridinit( icontxt, layout, nprow, npcol )
```

Input Parameters

icontxt
`INTEGER`. Integer handle indicating the system context to be used in creating the BLACS context. Call `blacs_get` to obtain a default system context.

layout
`CHARACTER*1`. Indicates how to map processes to BLACS grid. Options are:

- `'R'` : Use row-major natural ordering
- `'C'` : Use column-major natural ordering

- ELSE : Use row-major natural ordering

nprow — INTEGER. Indicates how many process rows the process grid should contain.

npcol — INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

icontxt — INTEGER. Integer handle to the created BLACS context.

Description

All BLACS codes must call this routine, or its sister routine blacs_gridmap. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine blacs_setup should be used to create the virtual machine.

This routine creates a simple nprow x npcol process grid. This process grid uses the first nprow * npcol processes, and assigns them to the grid in a row- or column-major natural ordering. If these process-to-grid mappings are unacceptable, call blacs_gridmap.

Examples of BLACS Routines Usage

blacs_get

blacs_gridmap

blacs_setup

blacs_gridmap

Maps available processes into BLACS process grid.

Syntax

```
call blacs_gridmap( icontxt, usermap, ldumap, nprow, npcol )
```

Input Parameters

icontxt — INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call blacs_get to obtain a default system context.

usermap — INTEGER. Array, dimension (*ldumap*, *npcol*), indicating the process-to-grid mapping.

ldumap	INTEGER. Leading dimension of the 2D array *usermap*. *ldumap* ≥ *nprow*.
nprow	INTEGER. Indicates how many process rows the process grid should contain.
npcol	INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

icontxt	INTEGER. Integer handle to the created BLACS context.

Description

All BLACS codes must call this routine, or its sister routine `blacs_gridinit`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine allows the user to map processes to the process grid in an arbitrary manner. `usermap(i,j)` holds the process number of the process to be placed in `{i, j}` of the process grid. On most distributed systems, this process number is a machine defined number between 0 ... *nprow*-1. For PVM, these node numbers are the PVM TIDS (Task IDs). The `blacs_gridmap` routine is intended for an experienced user. The `blacs_gridinit` routine is much simpler. `blacs_gridinit` simply performs a `gridmap` where the first `nprow * npcol` processes are mapped into the current grid in a row-major natural ordering. If you are an experienced user, `blacs_gridmap` allows you to take advantage of your system's actual layout. That is, you can map nodes that are physically connected to be neighbors in the BLACS grid, etc. The `blacs_gridmap` routine also opens the way for *multigridding*: you can separate your nodes into arbitrary grids, join them together at some later date, and then re-split them into new grids. `blacs_gridmap` also provides the ability to make arbitrary grids or subgrids (for example, a "nearest neighbor" grid), which can greatly facilitate operations among processes that do not fall on a row or column of the main process grid.

`blacs_setup`

Destruction Routines

This topic describes BLACS routines that destroy grids, abort processes, and free resources.

BLACS Destruction Routines

Routine name	Operation performed
blacs_freebuff	Frees BLACS buffer.
blacs_gridexit	Frees a BLACS context.
blacs_abort	Aborts all processes.
blacs_exit	Frees all BLACS contexts and releases all allocated memory.

blacs_freebuff

Frees BLACS buffer.

Syntax

```
call blacs_freebuff( icontxt, wait )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the BLACS context.
wait	INTEGER. Parameter indicating whether to wait for non-blocking operations or not. If equals 0, the operations should not be waited for; free only unused buffers. Otherwise, wait in order to free all buffers.

Description

This routine releases the BLACS buffer.

The BLACS have at least one internal buffer that is used for packing messages. The number of internal buffers depends on what platform you are running the BLACS on. On systems where memory is tight, keeping this buffer or buffers may become expensive. Call `freebuff` to release the buffer. However, the next call of a communication routine that requires packing reallocates the buffer.

The *wait* parameter determines whether the BLACS should wait for any non-blocking operations to be completed or not. If *wait* = 0, the BLACS free any buffers that can be freed without waiting. If *wait* is not 0, the BLACS free all internal buffers, even if non-blocking operations must be completed first.

blacs_gridexit

Frees a BLACS context.

Syntax

```
call blacs_gridexit( icontxt )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the BLACS context to be freed.

Description

This routine frees a BLACS context.

Release the resources when contexts are no longer needed. After freeing a context, the context no longer exists, and its handle may be re-used if new contexts are defined.

blacs_abort

Aborts all processes.

Syntax

```
call blacs_abort( icontxt, errornum )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the BLACS context to be aborted.
errornum	INTEGER. User-defined integer error number.

Description

This routine aborts all the BLACS processes, not only those confined to a particular context.

Use `blacs_abort` to abort all the processes in case of a serious error. Note that both parameters are input, but the routine uses them only in printing out the error message. The context handle passed in is not required to be a valid context handle.

blacs_exit

Frees all BLACS contexts and releases all allocated memory.

Syntax

```
call blacs_exit( continue )
```

Input Parameters

continue	INTEGER. Flag indicating whether message passing continues after the BLACS are done. If *continue* is non-zero, the user is assumed to continue using the machine after completing the BLACS. Otherwise, no message passing is assumed after calling this routine.

Description

This routine frees all BLACS contexts and releases all allocated memory.

This routine should be called when a process has finished all use of the BLACS. The *continue* parameter indicates whether the user will be using the underlying communication platform after the BLACS are finished. This information is most important for the PVM BLACS. If *continue* is set to 0, then `pvm_exit` is called; otherwise, it is not called. Setting *continue* not equal to 0 indicates that explicit PVM `send/recvs` will be called after the BLACS routines are used. Make sure your code calls `pvm_exit`. PVM users should either call `blacs_exit` or explicitly call `pvm_exit` to avoid PVM problems.

Examples of BLACS Routines Usage

Informational Routines

This topic describes BLACS routines that return information involving the process grid.

BLACS Informational Routines

Routine name	Operation performed
blacs_gridinfo	Returns information on the current grid.
blacs_pnum	Returns the system process number of the process in the process grid.
blacs_pcoord	Returns the row and column coordinates in the process grid.

blacs_gridinfo

Returns information on the current grid.

Syntax

```
call blacs_gridinfo( icontxt, nprow, npcol, myprow, mypcol )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.

Output Parameters

nprow	INTEGER. Number of process rows in the current process grid.
npcol	INTEGER. Number of process columns in the current process grid.
myprow	INTEGER. Row coordinate of the calling process in the process grid.
mypcol	INTEGER. Column coordinate of the calling process in the process grid.

Description

This routine returns information on the current grid. If the context handle does not point at a valid context, all quantities are returned as -1.

See Also

Examples of BLACS Routines Usage

blacs_pnum

Returns the system process number of the process in the process grid.

Syntax

```
call blacs_pnum( icontxt, prow, pcol )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
prow	INTEGER. Row coordinate of the process the system process number of which is to be determined.
pcol	INTEGER. Column coordinate of the process the system process number of which is to be determined.

Description

This function returns the system process number of the process at {PROW, PCOL} in the process grid.

See Also

Examples of BLACS Routines Usage

blacs_pcoord

Returns the row and column coordinates in the process grid.

Syntax

```
call blacs_pcoord( icontxt, pnum, prow, pcol )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
pnum	INTEGER. Process number the coordinates of which are to be determined. This parameter stand for the process number of the underlying machine, that is, it is a `tid` for PVM.

Output Parameters

prow	INTEGER. Row coordinates of the *pnum* process in the BLACS grid.
pcol	INTEGER. Column coordinates of the *pnum* process in the BLACS grid.

Description

Given the system process number, this function returns the row and column coordinates in the BLACS process grid.

Examples of BLACS Routines Usage

Miscellaneous Routines

This topic describes `blacs_barrier` routine.

BLACS Informational Routines

Routine name	Operation performed
blacs_barrier	Holds up execution of all processes within the indicated scope until they have all called the routine.

blacs_barrier

Holds up execution of all processes within the indicated scope.

Syntax

```
call blacs_barrier( icontxt, scope )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.

scope	CHARACTER*1. Parameter that indicates whether a process row (*scope*='R'), column ('C'), or entire grid ('A') will participate in the barrier.

Description

This routine holds up execution of all processes within the indicated scope until they have all called the routine.

Examples of BLACS Routines Usage

Example. BLACS Usage. Hello World

The following routine takes the available processes, forms them into a process grid, and then has each process check in with the process at {0,0} in the process grid.

```
      PROGRAM HELLO
*     -- BLACS example code --
*     Written by Clint Whaley 7/26/94
*     Performs a simple check-in type hello world
*     ..
*     .. External Functions ..
      INTEGER BLACS_PNUM
      EXTERNAL BLACS_PNUM
*     ..
*     .. Variable Declaration ..
      INTEGER CONTXT, IAM, NPROCS, NPROW, NPCOL, MYPROW, MYPCOL
      INTEGER ICALLER, I, J, HISROW, HISCOL
*
*     Determine my process number and the number of processes in
*     machine
*
      CALL BLACS_PINFO(IAM, NPROCS)
*
*     If in PVM, create virtual machine if it doesn't exist
*
      IF (NPROCS .LT. 1) THEN
         IF (IAM .EQ. 0) THEN
            WRITE(*, 1000)
            READ(*, 2000) NPROCS
         END IF
         CALL BLACS_SETUP(IAM, NPROCS)
      END IF
*
*     Set up process grid that is as close to square as possible
*
      NPROW = INT( SQRT( REAL(NPROCS) ) )
      NPCOL = NPROCS / NPROW
*
*     Get default system context, and define grid

*
      CALL BLACS_GET(0, 0, CONTXT)
      CALL BLACS_GRIDINIT(CONTXT, 'Row', NPROW, NPCOL)
      CALL BLACS_GRIDINFO(CONTXT, NPROW, NPCOL, MYPROW, MYPCOL)
*
*     If I'm not in grid, go to end of program
*
```

```
      IF ( (MYPROW.GE.NPROW) .OR. (MYPCOL.GE.NPCOL) ) GOTO 30

*
*     Get my process ID from my grid coordinates
*
      ICALLER = BLACS_PNUM(CONTXT, MYPROW, MYPCOL)
*
*     If I am process {0,0}, receive check-in messages from
*     all nodes
*
      IF ( (MYPROW.EQ.0) .AND. (MYPCOL.EQ.0) ) THEN

         WRITE(*,*) ' '

         DO 20 I = 0, NPROW-1
            DO 10 J = 0, NPCOL-1

               IF ( (I.NE.0) .OR. (J.NE.0) ) THEN
                  CALL IGERV2D(CONTXT, 1, 1, ICALLER, 1, I, J)
               END IF
*
*              Make sure ICALLER is where we think in process grid

*
              CALL BLACS_PCOORD(CONTXT, ICALLER, HISROW, HISCOL)
              IF ( (HISROW.NE.I) .OR. (HISCOL.NE.J) ) THEN
                 WRITE(*,*) 'Grid error!  Halting . . .'

                 STOP
              END IF
              WRITE(*, 3000) I, J, ICALLER

10          CONTINUE
20       CONTINUE
         WRITE(*,*) ' '
         WRITE(*,*) 'All processes checked in.  Run finished.'
*
*     All processes but {0,0} send process ID as a check-in

*
      ELSE

         CALL IGESD2D(CONTXT, 1, 1, ICALLER, 1, 0, 0)
      END IF

30    CONTINUE

      CALL BLACS_EXIT(0)

1000  FORMAT('How many processes in machine?')
2000  FORMAT(I)
3000  FORMAT('Process {',i2,',',i2,'} (node number =',I,
```

```
     $       ') has checked in.')

      STOP
      END
```

Example. BLACS Usage. PROCMAP

This routine maps processes to a grid using `blacs_gridmap`.

```
      SUBROUTINE PROCMAP(CONTEXT, MAPPING, BEGPROC, NPROW, NPCOL, IMAP)
*
*     -- BLACS example code --

*     Written by Clint Whaley 7/26/94
*     ..
*     .. Scalar Arguments ..
      INTEGER CONTEXT, MAPPING, BEGPROC, NPROW, NPCOL

*     ..
*     .. Array Arguments ..
      INTEGER IMAP(NPROW, *)
*     ..
*
*  Purpose
*  =======
*  PROCMAP maps NPROW*NPCOL processes starting from process BEGPROC to
*  the grid in a variety of ways depending on the parameter MAPPING.

*
*  Arguments

*  =========
*
*  CONTEXT      (output) INTEGER
*               This integer is used by the BLACS to indicate a context.
*               A context is a universe where messages exist and do not
*               interact with other context's messages.  The context
*               includes the definition of a grid, and each process's
*               coordinates in it.
*
*  MAPPING      (input) INTEGER
*               Way to map processes to grid.  Choices are:
*               1 : row-major natural ordering
*               2 : column-major natural ordering
*
*  BEGPROC      (input) INTEGER
*               The process number (between 0 and NPROCS-1) to use as

*               {0,0}. From this process, processes will be assigned
*               to the grid as indicated by MAPPING.
*
*  NPROW        (input) INTEGER
*               The number of process rows the created grid

*               should have.
*
*  NPCOL        (input) INTEGER
*               The number of process columns the created grid
```

```
*               should have.
*
*  IMAP         (workspace) INTEGER array of dimension (NPROW, NPCOL)
*               Workspace, where the array which maps the

*               processes to the grid will be stored for the
*               call to GRIDMAP.

Example. BLACS Usage. PARALLEL DOT PRODUCT

This routine does a bone-headed parallel double precision dot product of two vectors. Arguments are input on process {0,0}, and output everywhere else.

```
      DOUBLE PRECISION FUNCTION PDDOT( CONTEXT, N, X, Y )
*
*     -- BLACS example code --

*     Written by Clint Whaley 7/26/94
*     ..
*     .. Scalar Arguments ..
      INTEGER CONTEXT, N

*     ..
*     .. Array Arguments ..
      DOUBLE PRECISION X(*), Y(*)
*     ..
*
*  Purpose
*  =======
*  PDDOT is a restricted parallel version of the BLAS routine
*  DDOT.  It assumes that the increment on both vectors is one,
```

```
*  and that process {0,0} starts out owning the vectors and

*  has N.  It returns the dot product of the two N-length vectors
*  X and Y, that is, PDDOT = X' Y.
*
*  Arguments

*  =========
*
*  CONTEXT      (input) INTEGER
*               This integer is used by the BLACS to indicate a context.
*               A context is a universe where messages exist and do not
*               interact with other context's messages.  The context
*               includes the definition of a grid, and each process's
*               coordinates in it.
*
*  N            (input/output) INTEGER
*               The length of the vectors X and Y. Input
*               for {0,0}, output for everyone else.
*
*  X            (input/output) DOUBLE PRECISION array of dimension (N)
*               The vector X of PDDOT = X' Y. Input for {0,0},
*               output for everyone else.
*
*  Y            (input/output) DOUBLE PRECISION array of dimension (N)
*               The vector Y of PDDOT = X' Y. Input for {0,0},
*               output for everyone else.

Data Fitting Functions

Data Fitting functions in Intel® oneAPI Math Kernel Library (oneMKL) provide spline-based interpolation capabilities that you can use to approximate functions, function derivatives or integrals, and perform cell search operations.

The Data Fitting component is task based. The task is a data structure or descriptor that holds the parameters related to a specific Data Fitting operation. You can modify the task parameters using the task editing functionality of the library.

For definition of the implemented operations, see Mathematical Conventions.

Data Fitting routines use the following workflow to process a task:

1. Create a task or multiple tasks.
2. Modify the task parameters.
3. Perform a Data Fitting computation.
4. Destroy the task or tasks.

All Data Fitting functions fall into the following categories:

Task Creation and Initialization Routines - routines that create a new Data Fitting task descriptor and initialize the most common parameters, such as partition of the interpolation interval, values of the vector-valued function, and the parameters describing their structure.

Task Configuration Routines - routines that set, modify, or query parameters in an existing Data Fitting task.

Computational Routines - routines that perform Data Fitting computations, such as construction of a spline, interpolation, computation of derivatives and integrals, and search.

Task Destructors - routines that delete Data Fitting task descriptors and deallocate resources.

You can access the Data Fitting routines through the Fortran and C89/C99 language interfaces. You can also use the C89 interface with more recent versions of C/C++, or the Fortran 90 interface with programs written in Fortran 95.

The `${MKL}/include`directory of the Intel® oneAPI Math Kernel Library (oneMKL) contains the following Data Fitting header files:

- `mkl_df.f90`

You can find examples that demonstrate usage of Data Fitting routines in the `${MKL}/examples/datafittingf` directory.

Data Fitting Function Naming Conventions

The interfaces of the Data Fitting functions are in lowercase, while the names of the types and constants are in uppercase.

The names of all routines have the following structure:

`df[`*`datatype`*`]<`*`base_name`*`>`

where

- `df`is a prefix indicating that the routine belongs to the Data Fitting component of Intel® oneAPI Math Kernel Library (oneMKL).
- `[`*`datatype`*`]` field specifies the type of the input and/or output data and can be `s` (for the single precision real type), `d` (for the double precision real type), or `i` (for the integer type). This field is omitted in the names of the routines that are not data type dependent.
- `<`*`base_name`*`>` field specifies the functionality the routine performs. For example, this field can be `newtask1d`, `interpolate1d`, or `deletetask`

Data Fitting Function Data Types

The Data Fitting component provides routines for processing single and double precision real data types. The results of cell search operations are returned as a generic integer data type.

All Data Fitting routines use the following data type:

Type	Data Object
`TYPE(DF_TASK)`	Pointer to a task

NOTE
The actual size of the generic integer type is platform-dependent. Before compiling your application, you need to set an appropriate byte size for integers. For details, see section *Using the ILP64 Interface vs. LP64 Interface* of the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*.

Mathematical Conventions for Data Fitting Functions

This section explains the notation used for Data Fitting function descriptions. Spline notations are based on the terminology and definitions of [deBoor2001]. The Subbotin quadratic spline definition follows the conventions of [StechSub76]. The quasi-uniform partition definition is based on [Schumaker2007].

Mathematical Notation in the Data Fitting Component

Concept	Mathematical Notation
Partition of interpolation interval $[a, b]$, where • x_i denotes breakpoints. • $[x_i, x_{i+1})$ denotes a sub-interval (cell) of size $\Delta_i=x_{i+1}-x_i$.	$\{x_i\}_{i=1,...,n}$, where $a = x_1 < x_2 < ... < x_n = b$
Quasi-uniform partition of interpolation interval $[a, b]$	Partition $\{x_i\}_{i=1,...,n}$ which meets the constraint with a constant C defined as $1 \le M/m \le C$, where • $M = \max_{i=1,...,n-1} (\Delta_i)$ • $m = \min_{i=1,...,n-1} (\Delta_i)$ • $\Delta_i = x_{i+1} - x_i$
Vector-valued function of dimension p being fit	$f(x) = (f_1(x),..., f_p(x))$
Piecewise polynomial (PP) function f of order $k+1$	$f(x) := P_i(x)$, if $x \in [x_i, x_{i+1})$, $i = 1,..., n-1$ where • $\{x_i\}_{i= 1,..., n}$ is a strictly increasing sequence of breakpoints. • $P_i(x) = c_{i,0} + c_{i,1}(x - x_i) + ... + c_{i,k}(x - x_i)^k$ is a polynomial of degree k (order $k+1$) over the interval $x \in [x_i, x_{i+1})$.
Function p agrees with function f at the points $\{x_i\}_{i=1,...,n}$.	For every point ζ in sequence $\{x_i\}_{i=1,...,n}$ that occurs m times, the equality $p^{(i-1)}(\zeta) = f^{(i-1)}(\zeta)$ holds for all $i = 1,...,m$, where $p^{(i)}(t)$ is the derivative of the i-th order.
The k-th divided difference of function f at points $x_i,..., x_{i+k}$. This difference is the leading coefficient of the polynomial of order $k+1$ that agrees with f at $x_i,..., x_{i+k}$.	$[x_i,..., x_{i+k}] f$ In particular, • $[x_1]f = f(x_1)$ • $[x_1, x_2] f = (f(x_1) - f(x_2)) / (x_1 - x_2)$
A k-order derivative of interpolant $f(x)$ at interpolation site τ .	$f^{(k)}(\tau)$

Interpolants to the Function f at $x_1,..., x_n$ and Boundary Conditions

Concept	Mathematical Notation
Linear interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i)$, where • $x \in [x_i, x_{i+1})$ • $c_{1,i} = f(x_i)$

Concept	Mathematical Notation
	• $c_{2,i} = [x_i, x_{i+1}]f$ • $i = 1,\ldots, n\text{-}1$
Piecewise parabolic interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2$, $x \in [x_i, x_{i+1})$ Coefficients $c_{1,i}$, $c_{2,i}$, and $c_{3,i}$ depend on the conditions: • $P_i(x_i) = f(x_i)$ • $P_i(x_{i+1}) = f(x_{i+1})$ • $P_i((x_{i+1} + x_i) / 2) = v_{i+1}$ where parameter v_{i+1} depends on the interpolant being continuously differentiable: $P_{i-1}^{(1)}(x_i) = P_i^{(1)}(x_i)$

Piecewise parabolic Subbotin interpolant	$P(x) = P_i(x) = c_{1,i}+c_{2,i}(x-x_i)+c_{3,i}(x-x_i)^2+d_{3,i}((x-t_i)_+)^2$,
	where
	• $x \in [t_i, t_{i+1})$
	• $\{t_i\}_{i=1,\ldots,n+1}$ is a sequence of knots such that
	  • $t_1 = x_1$, $t_{n+1} = x_n$
	  • $t_i \in (x_{i-1}, x_i)$, $i = 2,\ldots, n$
	• $x_+ = f(x) = \begin{cases} 0, & \text{if } x < 0 \\ x, & \text{if } x \geq 0 \end{cases}$
	Coefficients $c_{1,i}$, $c_{2,i}$, $c_{3,i}$, and $d_{3,i}$ depend on the following conditions:
	• $P_i(x_i) = f(x_i)$, $P_i(x_{i+1}) = f(x_{i+1})$
	• $P(x)$ is a continuously differentiable polynomial of the second degree on $[t_i, t_{i+1})$, $i = 1,\ldots, n$.

Piecewise cubic Hermite interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3$, where • $x \in [x_i, x_{i+1})$ • $c_{1,i} = f(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2$ • $i = 1,\ldots, n\text{-}1$ • $s_i = f^{(1)}(x_i)$
Piecewise cubic Bessel interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3$, where • $x \in [x_i, x_{i+1})$ • $c_{1,i} = f(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2$ • $i = 1,\ldots, n\text{-}1$ • $s_i = (\Delta x_i[x_{i-1}, x_i]f + \Delta x_{i-1}[x_i, x_{i+1}]f) / (\Delta x_i + \Delta x_{i+1})$
Piecewise cubic Akima interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3$, where • $x \in [x_i, x_{i+1})$

Concept	Mathematical Notation
	• $c_{1,i} = f(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2$ • $i = 1,..., n-1$ • $s_i = (w_{i+1}[x_{i-1}, x_i]f + w_{i-1}[xf_i, x_{i+1}]f) / (w_{i+1} + w_{i-1})$, where $w_i = \lvert[x_i, x_{i+1}]f - [x_{i-1}, x_i]f\rvert$
Piecewise natural cubic interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3$, where • $x \in [x_i, x_{i+1})$ • $c_{1,i} = f(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2$ • $i = 1,..., n-1$ • Parameter s_i depends on the condition that the interpolant is twice continuously differentiable: $P_{i-1}^{(2)}(x_i) = P_i^{(2)}(x_i)$.
Not-a-knot boundary condition.	Parameters s_1 and s_n provide $P_1 = P_2$ and $P_{n-1} = P_n$, so that the first and the last interior breakpoints are inactive.
Free-end boundary condition.	$f''(x_1) = f''(x_n) = 0$
Look-up interpolator for discrete set of points $(x_1, y_1),..., (x_n, y_n)$.	$$y(x) = \begin{cases} y_1, & if\ x = x_1 \\ y_2, & if\ x = x_2 \\ \cdots & \\ y_n, & if\ x = x_n \\ error, & otherwise \end{cases}$$
Step-wise constant continuous right interpolator.	$$y(x) = \begin{cases} y_1, & \text{if } x_1 \le x < x_2 \\ y_2, & \text{if } x_2 \le x < x_3 \\ \cdots & \\ y_{n-1}, & \text{if } x_{n-1} \le x < x_n \\ y_n, & if\ x = x_n \end{cases}$$
Step-wise constant continuous left interpolator.	$$y(x) = \begin{cases} y_1, & \text{if } x = x_1 \\ y_2, & \text{if } x_1 < x \le x_2 \\ y_3, & \text{if } x_2 < x \le x_3 \\ \cdots & \\ y_n, & \text{if } x_{n-1} < x \le x_n \end{cases}$$

Data Fitting Usage Model

Consider an algorithm that uses the Data Fitting functions. Typically, such algorithms consist of four steps or stages:

1. Create a task. You can call the Data Fitting function several times to create multiple tasks.

```
status = dfdnewtask1d( task, nx, x, xhint, ny, y, yhint );
```

2. Modify the task parameters.

```
status = dfdeditppspline1d( task, s_order, c_type, bc_type, bc, ic_type, ic,
scoeff, scoeffhint );
```

3. Perform Data Fitting spline-based computations. You may reiterate steps 2-3 as needed.

```
status = dfdinterpolate1d(task, estimate, method, nsite, site, sitehint, ndorder,
dorder, datahint, r, rhint, cell );
```

4. Destroy the task or tasks.

```
status = dfdeletetask( task );
```

Data Fitting Usage Examples

You can get Fortran source code in the `.\examples\datafittingf`subdirectory of the Intel® oneAPI Math Kernel Library (oneMKL) installation directory.

Data Fitting Function Task Status and Error Reporting

The Data Fitting routines report a task status through integer values. Negative status values indicate errors, while positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The status codes have symbolic names predefined in the header file as integer constants via the `PARAMETER` operators.

If no error occurred, the function returns the `DF_STATUS_OK` code defined as zero:

```
INTEGER, PARAMETER::DF_STATUS_OK = 0
```

In case of an error, the function returns a non-zero error code that specifies the origin of the failure. Header files define the following status codes:

Status Codes in the Data Fitting Component

Status Code	Description
Common Status Codes	
`DF_STATUS_OK`	Operation completed successfully.
`DF_ERROR_NULL_TASK`	Data Fitting task is a `NULL` pointer.
`DF_ERROR_MEM_FAILURE`	Memory allocation failure.
`DF_ERROR_METHOD_NOT_SUPPORTED`	Requested method is not supported.
`DF_ERROR_COMP_TYPE_NOT_SUPPORTED`	Requested computation type is not supported.
`DF_ERROR_NULL_PTR`	Pointer to parameter is null.

Status Code	Description
Data Fitting Task Creation and Initialization, and Generic Editing Operations	
DF_ERROR_BAD_NX	Invalid number of breakpoints.
DF_ERROR_BAD_X	Array of breakpoints is invalid.
DF_ERROR_BAD_X_HINT	Invalid hint describing the structure of the partition.
DF_ERROR_BAD_NY	Invalid dimension of vector-valued function *y*.
DF_ERROR_BAD_Y	Array of function values is invalid.
DF_ERROR_BAD_Y_HINT	Invalid flag describing the structure of function *y*
Data Fitting Task-Specific Editing Operations	
DF_ERROR_BAD_SPLINE_ORDER	Invalid spline order.
DF_ERROR_BAD_SPLINE_TYPE	Invalid spline type.
DF_ERROR_BAD_IC_TYPE	Type of internal conditions used for spline construction is invalid.
DF_ERROR_BAD_IC	Array of internal conditions for spline construction is not defined.
DF_ERROR_BAD_BC_TYPE	Type of boundary conditions used in spline construction is invalid.
DF_ERROR_BAD_BC	Array of boundary conditions for spline construction is not defined.
DF_ERROR_BAD_PP_COEFF	Array of piecewise polynomial spline coefficients is not defined.
DF_ERROR_BAD_PP_COEFF_HINT	Invalid flag describing the structure of the piecewise polynomial spline coefficients.
DF_ERROR_BAD_PERIODIC_VAL	Function values at the endpoints of the interpolation interval are not equal as required in periodic boundary conditions.
DF_ERROR_BAD_DATA_ATTR	Invalid attribute of the pointer to be set or modified in Data Fitting task descriptor with the `df?editidxptr` task editor.
DF_ERROR_BAD_DATA_IDX	Index of the pointer to be set or modified in the Data Fitting task descriptor with the `df?editidxptr` task editor is out of the pre-defined range.
Data Fitting Computation Operations	
DF_ERROR_BAD_NSITE	Invalid number of interpolation sites.
DF_ERROR_BAD_SITE	Array of interpolation sites is not defined.
DF_ERROR_BAD_SITE_HINT	Invalid flag describing the structure of interpolation sites.
DF_ERROR_BAD_NDORDER	Invalid size of the array defining derivative orders to be computed at interpolation sites.

Status Code	Description
DF_ERROR_BAD_DORDER	Array defining derivative orders to be computed at interpolation sites is not defined.
DF_ERROR_BAD_DATA_HINT	Invalid flag providing additional information about partition or interpolation sites.
DF_ERROR_BAD_INTERP	Array of spline-based interpolation results is not defined.
DF_ERROR_BAD_INTERP_HINT	Invalid flag defining the structure of spline-based interpolation results.
DF_ERROR_BAD_CELL_IDX	Array of indices of partition cells containing interpolation sites is not defined.
DF_ERROR_BAD_NLIM	Invalid size of arrays containing integration limits.
DF_ERROR_BAD_LLIM	Array of the left-side integration limits is not defined.
DF_ERROR_BAD_RLIM	Array of the right-side integration limits is not defined.
DF_ERROR_BAD_INTEGR	Array of spline-based integration results is not defined.
DF_ERROR_BAD_INTEGR_HINT	Invalid flag providing the structure of the array of spline-based integration results.
DF_ERROR_BAD_LOOKUP_INTERP_SITE	Bad site provided for interpolation with look-up interpolator.

NOTE
The routine that estimates piecewise polynomial cubic spline coefficients can return internal error codes related to the specifics of the implementation. Such error codes indicate invalid input data or other issues unrelated to Data Fitting routines.

Data Fitting Task Creation and Initialization Routines

Task creation and initialization routines are functions used to create a new task descriptor and initialize its parameters. The Data Fitting component provides the `df?newtask1d` routine that creates and initializes a new task descriptor for a one-dimensional Data Fitting task.

df?newtask1d

Creates and initializes a new task descriptor for a one-dimensional Data Fitting task.

Syntax

status = dfsnewtask1d(*task*, *nx*, *x*, *xhint*, *ny*, *y*, *yhint*)

status = dfdnewtask1d(*task*, *nx*, *x*, *xhint*, *ny*, *y*, *yhint*)

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
nx	INTEGER	Number of breakpoints representing partition of interpolation interval [a, b].
x	REAL(KIND=4) DIMENSION(*) for dfsnewtask1d REAL(KIND=8) DIMENSION(*) for dfdnewtask1d	One-dimensional array containing the strictly sorted breakpoints from interpolation interval [a, b]. The structure of the array is defined by parameter *xhint*: • If partition is non-uniform or quasi-uniform, the array should contain *nx* strictly ordered values. • If partition is uniform, the array should contain two entries that represent endpoints of interpolation interval [a, b]. **Caution** The array must be strictly sorted. If it is unordered, the results of data fitting routines are not correct.
xhint	INTEGER	A flag describing the structure of partition *x*. For the list of possible values of *xhint*, see table "Hint Values for Partition *x*". If you set the flag to the DF_NO_HINT value, the library interprets the partition as non-uniform.
ny	INTEGER	Dimension of vector-valued function *y*.
y	REAL(KIND=4) DIMENSION(*) for dfsnewtask1d REAL(KIND=8) DIMENSION(*) for dfdnewtask1d	Vector-valued function *y*, array of size *nx***ny*. The storage format of function values in the array is defined by the value of flag *yhint*.
yhint	INTEGER	A flag describing the structure of array *y*. Valid hint values are listed in table "Hint Values for Vector-Valued Function *y*". If you set the flag to the DF_NO_HINT value, the library assumes that all *ny* coordinates of the vector-valued function *y* are provided and stored in row-major format.

Output Parameters

Name	Type	Description
task	TYPE(DF_TASK)	Descriptor of the task.
status	INTEGER	Status of the routine: • DF_STATUS_OK if the task is created successfully. • Non-zero error code if the task creation failed. See "Task Status and Error Reporting" for error code definitions.

Description

The df?newtask1d routine creates and initializes a new Data Fitting task descriptor with user-specified parameters for a one-dimensional Data Fitting task. The *x* and *nx* parameters representing the partition of interpolation interval [*a*, *b*] are mandatory. If you provide invalid values for these parameters, such as a NULL pointer *x* or the number of breakpoints smaller than two, the routine does not create the Data Fitting task and returns an error code.

If you provide a vector-valued function *y*, make sure that the function dimension *ny* and the array of function values *y* are both valid. If any of these parameters are invalid, the routine does not create the Data Fitting task and returns an error code.

If you store coordinates of the vector-valued function *y* in non-contiguous memory locations, you can set the *yhint* flag to DF_1ST_COORDINATE, and pass only the first coordinate of the function into the task creation routine. After successful creation of the Data Fitting task, you can pass the remaining coordinates using the df?editidxptr task editor.

If the routine fails to create the task descriptor, it returns a NULL task pointer.

The routine supports the following hint values for partition *x*:

Hint Values for Partition *x*

Value	Description
DF_NON_UNIFORM_PARTITION	Partition is non-uniform.
DF_QUASI_UNIFORM_PARTITION	Partition is quasi-uniform.
DF_UNIFORM_PARTITION	Partition is uniform.
DF_NO_HINT	No hint is provided. By default, partition is interpreted as non-uniform.

The routine supports the following hint values for the vector-valued function:

Hint Values for Vector-Valued Function *y*

Value	Description
DF_MATRIX_STORAGE_ROWS	Data is stored in row-major format according to C conventions.
DF_MATRIX_STORAGE_COLS	Data is stored in column-major format according to Fortran conventions.
DF_1ST_COORDINATE	The first coordinate of vector-valued data is provided.
DF_NO_HINT	No hint is provided. By default, the coordinates of vector-valued function *y* are provided and stored in row-major format.

NOTE
You must preserve the arrays *x* (breakpoints) and *y* (vector-valued functions) through the entire workflow of the Data Fitting computations for a task, as the task stores the addresses of the arrays for spline-based computations.

Task Configuration Routines

In order to configure tasks, you can use task editors and task query routines.

Task editors initialize or change the predefined Data Fitting task parameters. You can use task editors to initialize or modify pointers to arrays or parameter values.

Task editors can be task-specific or generic. Task-specific editors can modify more than one parameter related to a specific task. Generic editors modify a single parameter at a time.

The Data Fitting component of Intel® oneAPI Math Kernel Library (oneMKL) provides the following task editors:

Data Fitting Task Editors

Editor	Description	Type
df? editppspline1d	Changes parameters of the piecewise polynomial spline.	Task-specific
df?editptr	Changes a pointer in the task descriptor.	Generic
dfieditval	Changes a value in the task descriptor.	Generic
df?editidxptr	Changes a coordinate of data represented in matrix format, such as a vector-valued function or spline coefficients.	Generic

Task query routines are used to read the predefined Data Fitting task parameters. You can use task query routines to read the values of pointers or parameters.

Task query routines are generic (not task-specific), allowing you to read a single parameter at a time.

The Data Fitting component of the Intel® oneAPI Math Kernel Library (oneMKL) provides the following task query routines:

Data Fitting Task Query Routines

Editor	Description	Type
df?queryptr	Queries a pointer in the task descriptor.	Generic
dfiqueryval	Queries a value in the task descriptor.	Generic
df?queryidxptr	Queries a coordinate of data represented in matrix format, such as a vector-valued function or spline coefficients.	Generic

df?editppspline1d

Modifies parameters representing a spline in a Data Fitting task descriptor.

Syntax

status = dfseditppspline1d(*task*, *s_order*, *s_type*, *bc_type*, *bc*, *ic_type*, *ic*, *scoeff*, *scoeffhint*)

status = dfdeditppspline1d(*task*, *s_order*, *s_type*, *bc_type*, *bc*, *ic_type*, *ic*, *scoeff*, *scoeffhint*)

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
task	TYPE(DF_TASK)	Descriptor of the task.
s_order	INTEGER	Spline order. The parameter takes one of the values described in table "Spline Orders Supported by Data Fitting Functions".
s_type	INTEGER	Spline type. The parameter takes one of the values described in table "Spline Types Supported by Data Fitting Functions".
bc_type	INTEGER	Type of boundary conditions. The parameter takes one of the values described in table "Boundary Conditions Supported by Data Fitting Functions".
bc	REAL(KIND=4) DIMENSION(*) for dfseditppspline1d REAL(KIND=8) DIMENSION(*) for dfdeditppspline1d	Pointer to boundary conditions. The size of the array is defined by the value of parameter *bc_type*: • If you set free-end or not-a-knot boundary conditions, pass the NULL pointer to this parameter. • If you combine boundary conditions at the endpoints of the interpolation interval, pass an array of two elements. • If you set a boundary condition for the default quadratic spline or a periodic condition for Hermite or the default cubic spline, pass an array of one element.
ic_type	INTEGER	Type of internal conditions. The parameter takes one of the values described in table "Internal Conditions Supported by Data Fitting Functions".
ic	REAL(KIND=4) DIMENSION(*) for dfseditppspline1d REAL(KIND=8) DIMENSION(*) for dfdeditppspline1d	A non-NULL pointer to the array of internal conditions. The size of the array is defined by the value of parameter *ic_type*: • If you set first derivatives or second derivatives internal conditions (*ic_type*=DF_IC_1ST_DER or *ic_type*=DF_IC_2ND_DER), pass an array of n-1 derivative values at the internal points of the interpolation interval. • If you set the knot values internal condition for Subbotin spline (*ic_type*=DF_IC_Q_KNOT) and the knot partition is non-uniform, pass an array of n+1 elements. • If you set the knot values internal condition for Subbotin spline (*ic_type*=DF_IC_Q_KNOT) and the knot partition is uniform, pass an array of four elements.
scoeff	REAL(KIND=4) DIMENSION(*) for dfseditppspline1d REAL(KIND=8) DIMENSION(*) for dfdeditppspline1d	Spline coefficients. An array of size *ny*s_order**(*nx*-1). The storage format of the coefficients in the array is defined by the value of flag *scoeffhint*.

Name	Type	Description
scoeffhint	INTEGER	A flag describing the structure of the array of spline coefficients. For valid hint values, see table "Hint Values for Spline Coefficients". The library stores the coefficients in row-major format. The default value is DF_NO_HINT.

Output Parameters

Name	Type	Description
status	INTEGER	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

The editor modifies parameters that describe the order, type, boundary conditions, internal conditions, and coefficients of a spline. The spline order definition is provided in the "Mathematical Conventions" section. You can set the spline order to any value supported by Data Fitting functions. The table below lists the available values:

Spline Orders Supported by the Data Fitting Functions

Order	Description
DF_PP_STD	Artificial value. Use this value for look-up and step-wise constant interpolants only.
DF_PP_LINEAR	Piecewise polynomial spline of the second order (linear spline).
DF_PP_QUADRATIC	Piecewise polynomial spline of the third order (quadratic spline).
DF_PP_CUBIC	Piecewise polynomial spline of the fourth order (cubic spline).

To perform computations with a spline not supported by Data Fitting routines, set the parameter defining the spline order and pass the spline coefficients to the library in the supported format. For format description, see figure "Row-major Coefficient Storage Format".

The table below lists the supported spline types:

Spline Types Supported by Data Fitting Functions

Type	Description
DF_PP_DEFAULT	The default spline type. You can use this type with linear, quadratic, or user-defined splines.
DF_PP_SUBBOTIN	Quadratic splines based on Subbotin algorithm, [StechSub76].
DF_PP_NATURAL	Natural cubic spline.

Type	Description
DF_PP_HERMITE	Hermite cubic spline.
DF_PP_BESSEL	Bessel cubic spline.
DF_PP_AKIMA	Akima cubic spline.
DF_LOOKUP_INTERPOLANT	Look-up interpolant.
DF_CR_STEPWISE_CONST_INTERPOLANT	Continuous right step-wise constant interpolant.
DF_CL_STEPWISE_CONST_INTERPOLANT	Continuous left step-wise constant interpolant.

If you perform computations with look-up or step-wise constant interpolants, set the spline order to the DF_PP_STD value.

Construction of specific splines may require boundary or internal conditions. To compute coefficients of such splines, you should pass boundary or internal conditions to the library by specifying the type of the conditions and providing the necessary values. For splines that do not require additional conditions, such as linear splines, set condition types to DF_NO_BC and DF_NO_IC, and pass NULL pointers to the conditions. The table below defines the supported boundary conditions:

Boundary Conditions Supported by Data Fitting Functions

Boundary Condition	Description	Spline
DF_NO_BC	No boundary conditions provided.	All
DF_BC_NOT_A_KNOT	Not-a-knot boundary conditions.	Akima, Bessel, Hermite, natural cubic
DF_BC_FREE_END	Free-end boundary conditions.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_1ST_LEFT_DER	The first derivative at the left endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_1ST_RIGHT_DER	The first derivative at the right endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_2ST_LEFT_DER	The second derivative at the left endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_2ND_RIGHT_DER	The second derivative at the right endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_PERIODIC	Periodic boundary conditions.	Linear, all cubic splines
DF_BC_Q_VAL	Function value at point $(x_0 + x_1)/2$	Default quadratic

NOTE
To construct a natural cubic spline, pass these settings to the editor:

- `DF_PP_CUBIC` as the spline order,
- `DF_PP_NATURAL` as the spline type, and
- `DF_BC_FREE_END` as the boundary condition.

To construct a cubic spline with other boundary conditions, pass these settings to the editor:

- `DF_PP_CUBIC` as the spline order,
- `DF_PP_NATURAL` as the spline type, and
- the required type of boundary condition.

For Akima, Hermite, Bessel, and default cubic splines use the corresponding type defined in Table Spline Types Supported by Data Fitting Functions.

You can combine the values of boundary conditions with a bitwise `OR` operation. This permits you to pass combinations of first and second derivatives at the endpoints of the interpolation interval into the library. To pass a first derivative at the left endpoint and a second derivative at the right endpoint, set the boundary conditions to `DF_BC_1ST_LEFT_DER OR DF_BC_2ND_RIGHT_DER`.

You should pass the combined boundary conditions as an array of two elements. The first entry of the array contains the value of the boundary condition for the left endpoint of the interpolation interval, and the second entry - for the right endpoint. Pass other boundary conditions as arrays of one element.

For the conditions defined as a combination of valid values, the library applies the following rules to identify the boundary condition type:

- If not required for spline construction, the value of boundary conditions is ignored.
- Not-a-knot condition has the highest priority. If set, other boundary conditions are ignored.
- Free-end condition has the second priority after the not-a-knot condition. If set, other boundary conditions are ignored.
- Periodic boundary condition has the next priority after the free-end condition.
- The first derivative has higher priority than the second derivative at the right and left endpoints.

If you set the periodic boundary condition, make sure that function values at the endpoints of the interpolation interval are identical. Otherwise, the library returns an error code. The table below specifies the values to be provided for each type of spline if the periodic boundary condition is set.

Boundary Requirements for Periodic Conditions

Spline Type	Periodic Boundary Condition Support	Boundary Value
Linear	Yes	Not required
Default quadratic	No	
Subbotin quadratic	No	
Natural cubic	Yes	Not required
Bessel	Yes	Not required
Akima	Yes	Not required
Hermite cubic	Yes	First derivative
Default cubic	Yes	Second derivative

Internal conditions supported in the Data Fitting domain that you can use for the *ic_type* parameter are the following:

Internal Conditions Supported by Data Fitting Functions

Internal Condition	Description	Spline
DF_NO_IC	No internal conditions provided.	
DF_IC_1ST_DER	Array of first derivatives of size n-2, where n is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function.	Hermite cubic
DF_IC_2ND_DER	Array of second derivatives of size n-2, where n is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function.	Default cubic
DF_IC_Q_KNOT	Knot array of size n+1, where n is the number of breakpoints.	Subbotin quadratic

To construct a Subbotin quadratic spline, you have three options to get the array of knots in the library:

- If you do not provide the knots, the library uses the default values of knots $t = \{t_i\}$, $i = 0, ..., n$ according to the rule:

  $t_0 = x_0$, $t_n = x_{n-1}$, $t_i = (x_i + x_{i-1})/2$, $i = 1, ..., n - 1$.
- If you provide the knots in an array of size $n + 1$, the knots form a non-uniform partition. Make sure that the knot values you provide meet the following conditions:

  $t_0 = x_0$, $t_n = x_{n-1}$, $t_i \in (x_{i-1}, x_i)$, $i = 1,..., n - 1$.
- If you provide the knots in an array of size 4, the knots form a uniform partition

  $t_0 = x_0$, $t_1 = l$, $t_2 = r$, $t_3 = x_{n-1}$, where $l \in (x_0, x_1)$ and $r \in (x_{n-2}, x_{n-1})$.

  In this case, you need to set the value of the *ic_type* parameter holding the type of internal conditions to DF_IC_Q_KNOT OR DF_UNIFORM_PARTITION.

> **NOTE**
> Since the partition is uniform, perform an OR operation with the DF_UNIFORM_PARTITION partition hint value described in Table Hint Values for Partition x.

For computations based on look-up and step-wise constant interpolants, you can avoid calling the df?editppspline1d editor and directly call one of the routines for spline-based computation of spline values, derivatives, or integrals. For example, you can call the df?construct1d routine to construct the required spline with the given attributes, such as order or type.

The memory location of the spline coefficients is defined by the *scoeff* parameter. Make sure that the size of the array is sufficient to hold *ny***s_order* * (*nx*-1) values.

The df?editppspline1d routine supports the following hint values for spline coefficients:

Hint Values for Spline Coefficients

Order	Description
DF_1ST_COORDINATE	The first coordinate of vector-valued data is provided.
DF_NO_HINT	No hint is provided. By default, all sets of spline coefficients are stored in row-major format.

The coefficients for all coordinates of the vector-valued function are packed in memory one by one in successive order, from function y_1 to function y_{ny}.

Within each coordinate, the library stores the coefficients as an array, in row-major format:

$c_{1,0}$, $c_{1,1}$, ..., $c_{1,k}$, $c_{2,0}$, $c_{2,1}$, ..., $c_{2,k}$, ..., $c_{n-1,0}$, $c_{n-1,1}$, ..., $c_{n-1,k}$

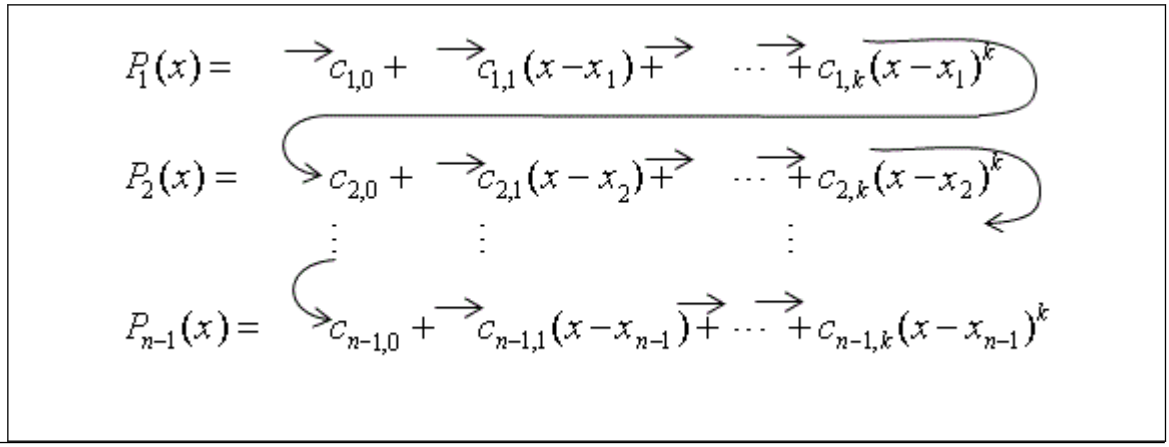
Mapping of the coefficients to storage in the *scoeff* array is described below, where $c_{i,j}$ is the jth coefficient of the function

$$P_i(x) = c_{i,0} + c_{i,1}(x - x_i) + \ldots + c_{i,k}(x - x_i)^k$$

.

See Mathematical Conventions for more details on nomenclature and interpolants.

Row-major Coefficient Storage Format



If you store splines corresponding to different coordinates of the vector-valued function at non-contiguous memory locations, do the following:

1. Set the *scoeffhint* flag to DF_1ST_COORDINATE and provide the spline for the first coordinate.
2. Pass the spline coefficients for the remaining coordinates into the Data Fitting task using the df?editidxptr task editor.

Using the df?editppspline1d task editor, you can provide to the Data Fitting task an already constructed spline that you want to use in computations. To ensure correct interpretation of the memory content, you should set the following parameters:

- Spline order and type, if appropriate. If the spline is not supported by the library, set the *s_type* parameter to DF_PP_DEFAULT.
- Pointer to the array of spline coefficients in row-major format.
- The *scoeffhint* parameter describing the structure of the array:
  - Set the *scoeffhint* flag to the DF_1ST_COORDINATE value to pass spline coefficients stored at different memory locations. In this case, you can set the parameters that describe boundary and internal conditions to zero.

- Use the default value DF_NO_HINT for all other cases.

Before passing an already constructed spline into the library, you should call the dfieditval task editor to provide the dimension of the spline DF_NY. See table "Parameters Supported by the dfieditval Task Editor" for details.

After you provide the spline to the Data Fitting task, you can run computations that use this spline.

NOTE
You must preserve the arrays *bc* (boundary conditions), *ic* (internal conditions), and *scoeff* (spline coefficients) through the entire workflow of the Data Fitting computations for a task, as the task stores the addresses of the arrays for spline-based computations.

df?editptr

Modifies a pointer to an array held in a Data Fitting task descriptor.

Syntax

status = dfseditptr(*task*, *ptr_attr*, *ptr*)

status = dfdeditptr(*task*, *ptr_attr*, *ptr*)

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
task	TYPE(DF_TASK)	Descriptor of the task.
ptr_attr	INTEGER	The parameter to change. For details, see the *Pointer Attribute* column in table "Pointers Supported by the df?editptr Task Editor".
ptr	REAL(KIND=4) DIMENSION(*) for dfseditptr REAL(KIND=8) DIMENSION(*) for dfdeditptr	New pointer. For details, see the *Purpose* column in table "Pointers Supported by the df?editptr Task Editor".

Output Parameters

Name	Type	Description
status	INTEGER	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The df?editptr editor replaces the pointer of type *ptr_attr* stored in a Data Fitting task descriptor with a new pointer *ptr*. The table below describes types of pointers supported by the editor:

Pointers Supported by the df?editptr Task Editor

Pointer Attribute	Purpose
DF_X	Partition *x* of the interpolation interval, an array of strictly sorted breakpoints. **Caution** The array must be strictly sorted. If it is unordered, the results of data fitting routines are not correct.
DF_Y	Vector-valued function *y*
DF_IC	Internal conditions for spline construction. For details, see table "Internal Conditions Supported by Data Fitting Functions".
DF_BC	Boundary conditions for spline construction. For details, see table "Boundary Conditions Supported by Data Fitting Functions".
DF_PP_SCOEFF	Spline coefficients

You can use df?editptr to modify different types of pointers including pointers to the vector-valued function and spline coefficients stored in contiguous memory. Use the df?editidxptr editor if you need to modify pointers to coordinates of the vector-valued function or spline coefficients stored at non-contiguous memory locations.

If you modify a partition of the interpolation interval, then you should call the dfieditval task editor with the corresponding value of DF_XHINT, even if the structure of the partition remains the same.

If you pass a NULL pointer to the df?editptr task editor, the task remains unchanged and the routine returns an error code. For the predefined error codes, please see "Task Status and Error Reporting".

NOTE
You must preserve the arrays *x* (breakpoints), *y* (vector-valued functions), *bc* (boundary conditions), *ic* (internal conditions), and *scoeff* (spline coefficients) through the entire workflow of the Data Fitting computations which use those arrays, as the task stores the addresses of the arrays for spline-based computations.

dfieditval

Modifies a parameter value in a Data Fitting task descriptor.

Syntax

status = dfieditval(*task*, *val_attr*, *val*)

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
task	TYPE(DF_TASK)	Descriptor of the task.

Name	Type	Description
val_attr	INTEGER	The parameter to change. See table "Parameters Supported by the dfieditval Task Editor".
val	INTEGER	A new parameter value. See table "Parameters Supported by the dfieditval Task Editor".

Output Parameters

Name	Type	Description
status	INTEGER	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The dfieditval task editor replaces the parameter of type *val_attr* stored in a Data Fitting task descriptor with a new value *val*. The table below describes valid types of parameter *val_attr* supported by the editor:

Parameters Supported by the dfieditval Task Editor

Parameter Attribute	Purpose
DF_NX	Number of breakpoints
DF_XHINT	A flag describing the structure of partition. See table "Hint Values for Partition *x*" for the list of available values.
DF_NY	Dimension of the vector-valued function
DF_YHINT	A flag describing the structure of the vector-valued function. See table "Hint Values for Vector Function *y*" for the list of available values.
DF_SPLINE_ORDER	Spline order. See table "Spline Orders Supported by Data Fitting Functions" for the list of available values.
DF_SPLINE_TYPE	Spline type. See table "Spline Types Supported by Data Fitting Functions" for the list of available values.
DF_BC_TYPE	Type of boundary conditions used in spline construction. See table "Boundary Conditions Supported by Data Fitting Functions" for the list of available values.
DF_IC_TYPE	Type of internal conditions used in spline construction. See table "Internal Conditions Supported by Data Fitting Functions" for the list of available values.
DF_PP_COEFF_HINT	A flag describing the structure of spline coefficients. See table "Hint Values for Spline Coefficients" for the list of available values.
DF_CHECK_FLAG	A flag which controls checking of Data Fitting parameters. See table "Possible Values for the DF_CHECK_FLAG Parameter" for the list of available values.

If you pass a zero value for the parameter describing the size of the arrays that hold coefficients for a partition, a vector-valued function, or a spline, the parameter held in the Data fitting task remains unchanged and the routine returns an error code. For the predefined error codes, see "Task Status and Error Reporting".

Possible Values for the DF_CHECK_FLAG Parameter

Value	Description
DF_ENABLE_CHECK_FLAG	Checks the correctness of parameters of Data Fitting computational routines (default mode).
DF_DISABLE_CHECK_FLAG	Disables checking of the correctness of parameters of Data Fitting computational routines.

Use DF_CHECK_FLAG for *val_attr* in order to control validation of parameters of Data Fitting computational routines such as df?construct1d, df?interpolate1d/df?interpolateex1d, and df?searchcells1d/df?searchcellsex1d, which can perform better with a small number of interpolation sites or integration limits (fewer than one dozen). The default mode, with checking of parameters enabled, should be used as you develop a Data Fitting-based application. After you complete development you can disable parameter checking in order to improve the performance of your application.

If you modify the parameter describing dimensions of the arrays that hold the vector-valued function or spline coefficients in contiguous memory, you should call the df?editptr task editor with the corresponding pointers to the vector-valued function or spline coefficients even when this pointer remains unchanged. Call the df?editidxptr editor if those arrays are stored in non-contiguous memory locations.

You must call the dfieditval task editor to edit the structure of the partition DF_XHINT every time you modify a partition using df?editptr, even if the structure of the partition remains the same.

df?editidxptr

Modifies a pointer to the memory representing a coordinate of the data stored in matrix format.

Syntax

status = dfseditidxptr(*task*, *ptr_attr*, *idx*, *ptr*)

status = dfdeditidxptr(*task*, *ptr_attr*, *idx*, *ptr*)

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
task	TYPE(DF_TASK)	Descriptor of the task.
ptr_attr	INTEGER	Type of the data to be modified. The parameter takes one of the values described in "Data Attributes Supported by the df?editidxptr Task Editor".
idx	INTEGER	Index of the coordinate whose pointer is to be modified.
ptr	REAL(KIND=4) DIMENSION(*) for dfseditidxptr	Pointer to the data that holds values of coordinate *idx*. For details, see table "Data Attributes Supported by the df?editidxptr Task Editor".

Name	Type	Description
	REAL(KIND=8) DIMENSION(*) for dfdeditidxptr	

Output Parameters

Name	Type	Description
status	INTEGER	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The routine modifies a pointer to the array that holds the *idx* coordinate of vector-valued function *y* or the pointer to the array of spline coefficients corresponding to the given coordinate.

You can use the editor if you need to pass into a Data Fitting task or modify the pointer to coordinates of the vector-valued function or spline coefficients held at non-contiguous memory locations. Do not use the editor for coordinates at contiguous memory locations in row-major format.

Before calling this editor, make sure that you have created and initialized the task using a task creation function or a relevant editor such as the generic or specific df?editppspline1d editor.

Data Attributes Supported by the df?editidxptr Task Editor

Data Attribute	Description
DF_Y	Vector-valued function *y*
DF_PP_SCOEFF	Piecewise polynomial spline coefficients

When using df?editidxptr, you might receive an error code in the following cases:

- You passed an unsupported parameter value into the editor.
- The value of the index exceeds the predefined value that equals the dimension *ny* of the vector-valued function.
- You pass a NULL pointer to the editor. In this case, the task remains unchanged.
- You pass a pointer to the *idx* coordinate of the vector-valued function you provided to contiguous memory in column-major format.

The code example below demonstrates how to use the editor for providing values of a vector-valued function stored in two non-contiguous arrays:

df?queryptr

Reads a pointer to an array held in a Data Fitting task descriptor.

Syntax

status = dfsqueryptr(*task*, *ptr_attr*, *ptr*)

status = dfdqueryptr(*task*, *ptr_attr*, *ptr*)

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
task	TYPE(DF_TASK)	Descriptor of the task.
ptr_attr	INTEGER	The parameter to query. The query routine supports pointer attributes described in the table "Pointers Supported by the df?editptr Task Editor". For details, see the *Pointer Attribute* column in the table.

Output Parameters

Name	Type	Description
ptr	INTEGER(KIND=8)	Pointer to array returned by the query routine. For details, see the *Purpose* column in table "Pointers Supported by the df?editptr Task Editor".
status	INTEGER	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The df?queryptr routine returns the pointer of type *ptr_attr* stored in a Data Fitting task descriptor as parameter *ptr*. Attributes of the pointers supported by the query function are identical to those supported by the editor df?editptr editor in the table "Pointers Supported by the df?editptr Task Editor".

You can use df?queryptr to read different types of pointers including pointers to the vector-valued function and spline coefficients stored in contiguous memory.

dfiqueryval

Reads a parameter value in a Data Fitting task descriptor.

Syntax

status = dfiqueryval(*task*, *val_attr*, *val*)

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
task	TYPE(DF_TASK)	Descriptor of the task.

Name	Type	Description
val_attr	INTEGER	The parameter to query. The query function supports the parameter attributes described in "Parameters Supported by the dfieditval Task Editor".

Output Parameters

Name	Type	Description
val	INTEGER	The parameter value returned by the query function. See table "Parameters Supported by the dfieditval Task Editor".
status	INTEGER	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The dfiqueryval routine returns a parameter of type *val_attr* stored in a Data Fitting task descriptor as parameter *val*. The query function supports the parameter attributes described in "Parameters Supported by the dfieditval Task Editor".

df?queryidxptr

Reads a pointer to the memory representing a coordinate of the data stored in matrix format.

Syntax

status = dfsqueryidxptr(*task*, *ptr_attr*, *idx*, *ptr*)

status = dfdqueryidxptr(*task*, *ptr_attr*, *idx*, *ptr*)

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
task	TYPE(DF_TASK)	Descriptor of the task.
ptr_attr	INTEGER	Pointer attribute to query. The parameter takes one of the attributes described in "Data Attributes Supported by the df?editidxptr Task Editor".
idx	INTEGER	Index of the coordinate of the pointer to query.

Output Parameters

Name	Type	Description
ptr	INTEGER(KIND=8)	Pointer to the data that holds values of coordinate *idx* returned. For details, see table "Data Attributes Supported by the df?editidxptr Task Editor".
status	INTEGER	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The routine returns a pointer to the array that holds the *idx* coordinate of vector-valued function *y* or the pointer to the array of spline coefficients corresponding to the given coordinate.

You can use the query routine if you need the pointer to coordinates of the vector-valued function or spline coefficients held at non-contiguous memory locations or at a contiguous memory location in row-major format (the default storage format for spline coefficients).

Before calling this query routine, make sure that you have created and initialized the task using a task creation function or a relevant editor such as the generic or specific df?editppspline1d editor.

When using df?queryidxptr, you might receive an error code in the following cases:

- You passed an unsupported parameter value into the editor.
- The value of the index exceeds the predefined value that equals the dimension *ny* of the vector-valued function.
- You request the pointer to the *idx* coordinate of the vector-valued function you provided to contiguous memory in column-major format.

Data Fitting Computational Routines

Data Fitting computational routines are functions used to perform spline-based computations, such as:

- spline construction
- computation of values, derivatives, and integrals of the predefined order
- cell search

Once you create a Data Fitting task and initialize the required parameters, you can call computational routines as many times as necessary.

The table below lists the available computational routines:

Data Fitting Computational Routines

Routine	Description
df?construct1d	Constructs a spline for a one-dimensional Data Fitting task.
df?interpolate1d	Computes spline values and derivatives.
df?interpolateex1d	Computes spline values and derivatives by calling user-provided interpolants.
df?integrate1d	Computes spline-based integrals.

Routine	Description
df?integrateex1d	Computes spline-based integrals by calling user-provided integrators.
df?searchcells1d	Finds indices of cells containing interpolation sites.
df?searchcellsex1d	Finds indices of cells containing interpolation sites by calling user-provided cell searchers.

If a Data Fitting computation completes successfully, the computational routines return the DF_STATUS_OK code. If an error occurs, the routines return an error code specifying the origin of the failure. Some possible errors are the following:

- The task pointer is NULL.
- Memory allocation failed.
- The computation failed for another reason.

For the list of available status codes, see "Task Status and Error Reporting".

NOTE
Data Fitting computational routines do not control errors for floating-point conditions, such as overflow, gradual underflow, or operations with Not a Number (NaN) values.

df?construct1d

Syntax

Constructs a spline of the given type.

status = dfsconstruct1d(*task*, *s_format*, *method*)

status = dfdconstruct1d(*task*, *s_format*, *method*)

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
task	TYPE(DF_TASK)	Descriptor of the task.
s_format	INTEGER	Spline format. The supported value is DF_PP_SPLINE.
method	INTEGER	Construction method. The supported value is DF_METHOD_STD.

Output Parameters

Name	Type	Description
status	INTEGER	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

Before calling df?construct1d, you need to create and initialize the task, and set the parameters representing the spline. Then you can call the df?construct1d routine to construct the spline. The format of the spline is defined by parameter *s_format*. The method for spline construction is defined by parameter *method*. Upon successful construction, the spline coefficients are available in the user-provided memory location in the format you set through the Data Fitting editor. For the available storage formats, see table "Hint Values for Spline Coefficients".

df?interpolate1d/df?interpolateex1d

Runs data fitting computations.

Syntax

status = dfsinterpolate1d(*task*, *type*, *method*, *nsite*, *site*, *sitehint*, *ndorder*, *dorder*, *datahint*, *r*, *rhint*, *cell*)

status = dfdinterpolate1d(*task*, *type*, *method*, *nsite*, *site*, *sitehint*, *ndorder*, *dorder*, *datahint*, *r*, *rhint*, *cell*)

status = dfsinterpolateex1d(*task*, *type*, *method*, *nsite*, *site*, *sitehint*, *ndorder*, *dorder*, *datahint*, *r*, *rhint*, *cell*, *le_cb*, *le_params*, *re_cb*, *re_params*, *i_cb*, *i_params*, *search_cb*, *search_params*)

status = dfdinterpolateex1d(*task*, *type*, *method*, *nsite*, *site*, *sitehint*, *ndorder*, *dorder*, *datahint*, *r*, *rhint*, *cell*, *le_cb*, *le_params*, *re_cb*, *re_params*, *i_cb*, *i_params*, *search_cb*, *search_params*)

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
task	TYPE(DF_TASK)	Descriptor of the task.
type	INTEGER	Type of spline-based computations. The parameter takes one or more values combined with an OR operation. For the list of possible values, see table "Computation Types Supported by the df?interpolate1d/ df?interpolate1d Routines".
method	INTEGER	Computation method. The supported value is DF_METHOD_PP.
nsite	INTEGER	Number of interpolation sites.
site	REAL(KIND=4) DIMENSION(*) for dfsinterpolate1d/ dfsinterpolateex1d	Array of interpolation sites of size *nsite*. The structure of the array is defined by the *sitehint* parameter: • If sites form a non-uniform partition, the array should contain *nsite* values.

Name	Type	Description
	REAL(KIND=8) DIMENSION(*) for dfdinterpolate1d/ dfdinterpolateex1d	• If sites form a uniform partition, the array should contain two entries that represent the left and the right interpolation sites. The first entry of the array contains the left-most interpolation point. The second entry of the array contains the right-most interpolation point.
sitehint	INTEGER	A flag describing the structure of the interpolation sites. For the list of possible values of *sitehint*, see table "Hint Values for Interpolation Sites". If you set the flag to DF_NO_HINT, the library interprets the site-defined partition as non-uniform.
ndorder	INTEGER	Maximal derivative order increased by one to be computed at interpolation sites.
dorder	INTEGER DIMENSION(*)	Array of size *ndorder* that defines the order of the derivatives to be computed at the interpolation sites. If all the elements in *dorder* are zero, the library computes the spline values only. If you do not need interpolation computations, set *ndorder* to zero and pass a NULL pointer to *dorder*.
datahint	REAL(KIND=4) DIMENSION(*) for dfsinterpolate1d/ dfsinterpolateex1d REAL(KIND=8) DIMENSION(*) for dfdinterpolate1d/ dfdinterpolateex1d	Array that contains additional information about the structure of partition *x* and interpolation sites. This data helps to speed up the computation. If you provide a NULL pointer, the routine uses the default settings for computations. For details on the *datahint* array, see table "Structure of the *datahint* Array".
r	REAL(KIND=4) DIMENSION(*) for dfsinterpolate1d/ dfsinterpolateex1d REAL(KIND=8) DIMENSION(*) for dfdinterpolate1d/ dfdinterpolateex1d	Array for results. If you do not need spline-based interpolation, set this pointer to NULL.
rhint	INTEGER	A flag describing the structure of the results. For the list of possible values of *rhint*, see table "Hint Values for the *rhint* Parameter". If you set the flag to DF_NO_HINT, the library stores the result in row-major format.
cell	INTEGER DIMENSION(*)	Array of cell indices in partition *x* that contain the interpolation sites. Provide this parameter as input if *type* is DF_INTERP_USER_CELL. If you do not need cell indices, set this parameter to NULL.
le_cb	INTEGER	User-defined callback function for extrapolation at the sites to the left of the interpolation interval.

Name	Type	Description
le_params	INTEGER DIMENSION(*)	Pointer to additional user-defined parameters passed by the library to the *le_cb* function.
re_cb	INTEGER	User-defined callback function for extrapolation at the sites to the right of the interpolation interval.
re_params	INTEGER DIMENSION(*)	Pointer to additional user-defined parameters passed by the library to the *re_cb* function.
i_cb	INTEGER	User-defined callback function for interpolation within the interpolation interval.
i_params	INTEGER DIMENSION(*)	Pointer to additional user-defined parameters passed by the library to the *i_cb* function.
search_cb	INTEGER	User-defined callback function for computing indices of cells that can contain interpolation sites.
search_params	INTEGER DIMENSION(*)	Pointer to additional user-defined parameters passed by the library to the *search_cb* function.

Output Parameters

Name	Type	Description
status	INTEGER	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.
r		Contains results of computations at the interpolation sites.
cell		Array of cell indices in partition *x* that contain the interpolation sites, which is computed if *type* is DF_CELL.

Description

The df?interpolate1d/df?interpolateex1d routine performs spline-based computations with user-defined settings. The routine supports two types of computations for interpolation sites provided in array *site*:

Computation Types Supported by the df?interpolate1d/df?interpolateex1d Routines

Type	Description
DF_INTERP	Compute derivatives of predefined order. The derivative of the zero order is the spline value.
DF_INTERP_USER_CELL	Compute derivatives of predefined order given user-provided cell indices. The derivative of the zero order is the spline value.

Type	Description
	For this type of the computations you should provide a valid *cell* array, which holds the indices of cells in the *site* array containing relevant interpolation sites.
DF_CELL	Compute indices of cells in partition *x* that contain the sites.

If the indices of cells which contain interpolation types are available before the call to df?interpolate1d/ df?interpolateex1d, you can improve performance by using the DF_INTERP_USER_CELL computation type.

NOTE
If you pass any combination of DF_INTERP, DF_INTERP_USER_CELL, and DF_CELL computation types to the routine, the library uses the DF_INTERP_USER_CELL computation mode.

If you specify DF_INTERP_USER_CELL computation mode and a user-defined callback function for computing cell indices to df?interpolateex1d, the library uses the DF_INTERP_USER_CELL computation mode, and the call-back function is not called.

If the sites do not belong to interpolation interval [*a*, *b*] , the library uses:

- polynomial P_0 of the spline constructed on interval $[x_0, x_1]$ for computations at the sites to the left of *a*.
- polynomial P_{n-2} of the spline constructed on interval $[x_{n-2}, x_{n-1}]$ for computations at the sites to the right of *b*.

Interpolation sites support the following hints:

Hint Values for Interpolation Sites

Value	Description
DF_NON_UNIFORM_PARTITION	Partition is non-uniform.
DF_UNIFORM_PARTITION	Partition is uniform.
DF_SORTED_DATA	Interpolation sites are sorted in the ascending order and define a non-uniform partition.
DF_NO_HINT	No hint is provided. By default, the partition defined by interpolation sites is interpreted as non-uniform.

NOTE
If you pass a sorted array of interpolation sites to the Intel® oneAPI Math Kernel Library (oneMKL), set the*sitehint* parameter to the DF_SORTED_DATA value. The library uses this information when choosing the search algorithm and ignores any other data hints about the structure of the interpolation sites.

Data Fitting computation routines can use the following hints to speed up the computation:

- DF_UNIFORM_PARTITION describes the structure of breakpoints and the interpolation sites.
- DF_QUASI_UNIFORM_PARTITION describes the structure of breakpoints.

Pass the above hints to the library when appropriate.

For spline-based interpolation, you should set the derivatives whose values are required for the computation. You can provide the derivatives by setting the `dorder` array of size `ndorder` as follows:

$$dorder(i) = \begin{cases} 1, \text{ if derivative of the order } i-1 \text{ is required} \\ 0, \text{ otherwise} \end{cases} \quad i = 1, ..., ndorder$$

Orders of derivatives i_d(d = 1, 2, .., *nder*), corresponding to non-zero derivatives to be calculated, form the array $\{i_d\}$ of length *nder*≤`ndorder`.

The storage format for the interpolation results is specified using the `rhint` parameter values. For each storage format, Table Hint Values for the `rhint` Parameter describes how to get the result $R(j, s, i_d)$ from array `r`, for function index j(1 ≤j≤*yn*), site number s(1 ≤s≤*nsite*), and derivative index i_d(1 ≤d≤*nder*), where *yn* is the number of functions, *nsite* is the number of sites, and *nder* is the total number of non-zero derivatives for interpolation. The array `r` can be either a one-dimensional array of size *ny***nder**`nsite` or a three-dimensional array with the dimensions described in the table.

Hint Values for the `rhint` Parameter

Value	Location of $R(j, s, i_d)$, One-dimensional Array Storage	Location of $R(j, s, i_d)$, Three-dimensional Array Storage
`DF_MATRIX_STORAGE_FUNCS_SITES_DERS` (`DF_MATRIX_STORAGE_ROWS`)	`r(d - 1 + nder*(s - 1 + nsite*(j - 1)) + 1)`	`r(d, s, j)` `r` declared as `r(nder, nsite, ny)`.
`DF_MATRIX_STORAGE_FUNCS_DERS_SITES` (`DF_MATRIX_STORAGE_COLS`)	`r(s - 1 + nsite*(d - 1 + nder*(j - 1)) + 1)`	`r(s, d, j)` `r` declared as `r(nsite, nder, ny)`.
`DF_MATRIX_STORAGE_SITES_FUNCS_DERS`	`r(d - 1 + nder*(j - 1 + ny*(s - 1)) + 1)`	`r(d, j, s)` `r` declared as `r(nder, ny, nsite)`.
`DF_MATRIX_STORAGE_SITES_DERS_FUNCS`	`r(j - 1 + ny*(d - 1 + nder*(s - 1)) + 1)`	`r(j, d, s)` `r` declared as `r(ny, nder, nsite)`.
`DF_NO_HINT`	No hint is provided. By default, the results are stored as in `rhint` = `DF_MATRIX_STORAGE_FUNCS_SITES_DERS`.	

The following figures show the structure of the storage formats. Each shows sequential memory layout line by line, left to right.

- Storage in `r` for `rhint` = `DF_MATRIX_STORAGE_FUNCS_SITES_DERS` (`DF_MATRIX_STORAGE_ROWS`):

$$\begin{array}{cccc|cccc|c} R(1,1,i_1) & R(1,2,i_1) & \dots & R(1,nsite,i_1) & R(2,1,i_1) & R(2,2,i_1) & \dots & R(2,nsite,i_1) & \dots \\ R(1,1,i_2) & R(1,2,i_2) & \dots & R(1,nsite,i_2) & R(2,1,i_2) & R(2,2,i_2) & \dots & R(2,nsite,i_2) & \dots \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ R(1,1,i_{nder}) & R(1,2,i_{nder}) & \dots & R(1,nsite,i_{nder}) & R(2,1,i_{nder}) & R(2,2,i_{nder}) & \dots & R(2,nsite,i_{nder}) & \dots \end{array}$$

- Storage in `r` for `rhint` = `DF_MATRIX_STORAGE_FUNCS_DERS_SITES` (`DF_MATRIX_STORAGE_COLS`):

$R(1,1,i_1)$ $R(1,1,i_2)$ ... $R(1,1,i_{nder})$ $R(1,2,i_1)$ $R(1,2,i_2)$ ... $R(1,2,i_{nder})$ ... ... $R(1,nsite,i_1)$ $R(1,nsite,i_2)$ ... $R(1,nsite,i_{nder})$	$R(2,1,i_1)$ $R(2,1,i_2)$ ... $R(2,1,i_{nder})$ $R(2,2,i_1)$ $R(2,2,i_2)$ ... $R(2,2,i_{nder})$ ... ... $R(2,nsite,i_1)$ $R(2,nsite,i_2)$ ... $R(2,nsite,i_{nder})$	... ...

- Storage in `r` for `rhint = DF_MATRIX_STORAGE_SITES_FUNCS_DERS`:

$R(1,1,i_1)$ $R(2,1,i_1)$ ... $R(ny,1,i_1)$ $R(1,1,i_2)$ $R(2,1,i_2)$ ... $R(ny,1,i_2)$ ... ... $R(1,1,i_{nder})$ $R(2,1,i_{nder})$ ... $R(ny,1,i_{nder})$	$R(1,2,i_1)$ $R(2,2,i_1)$ ... $R(ny,2,i_1)$ $R(1,2,i_2)$ $R(2,2,i_2)$ ... $R(ny,2,i_2)$ ... ... $R(1,2,i_{nder})$ $R(2,2,i_{nder})$ ... $R(ny,2,i_{nder})$	... ...

- Storage in `r` for `rhint = DF_MATRIX_STORAGE_SITES_DERS_FUNCS`:

$R(1,1,i_1)$ $R(1,1,i_2)$ ... $R(1,1,i_{nder})$ $R(2,1,i_1)$ $R(2,1,i_2)$ ... $R(2,1,i_{nder})$ ... ... $R(ny,1,i_1)$ $R(ny,1,i_2)$ ... $R(ny,1,i_{nder})$	$R(1,2,i_1)$ $R(1,2,i_2)$ ... $R(1,2,i_{nder})$ $R(2,2,i_1)$ $R(2,2,i_2)$ ... $R(2,2,i_{nder})$ ... ... $R(ny,2,i_1)$ $R(ny,2,i_2)$ ... $R(ny,2,i_{nder})$	... ...

To speed up Data Fitting computations, use the `datahint` parameter that provides additional information about the structure of the partition and interpolation sites. This data represents a floating-point or a double array with the following structure:

Structure of the `datahint` Array

Element Number	Description
1	Task dimension
2	Type of additional information
3	Reserved field
4	The total number *q* of elements containing additional information.
5	Element (1)
...	...
q+4	Element (*q*)

Data Fitting computation functions support the following types of additional information for `datahint(2)`:

Types of Additional Information

Type	Element Number	Parameter
`DF_NO_APRIORI_INFO`	0	No parameters are provided. Information about the data structure is absent.

Type	Element Number	Parameter
DF_APRIORI_MOST_LIKELY_CELL	1	Index of the cell that is likely to contain interpolation sites.

To compute indices of the cells that contain interpolation sites, provide the pointer to the array of size *nsite* for the results. The library supports the following scheme of cell indexing for the given partition$\{x_i\}$, i=1,...,nx:

cell(*j*) = i, if *site*(*j*) $\in[x_i, x_{i+1})$, i = 0,..., *nx* - 2,

cell(*j*) = *nx* - 1, if *site*(*j*) $\in[x_{nx-1}, x_{nx}]$,

cell(*j*) = *nx*, if *site*(*j*) $\in(x_{nx}, x_{nx+1}]$,

where

- $x_0 = -\infty$
- $x_{nx+1} = +\infty$
- j = 1,..., *nsite*

To perform interpolation computations with spline types unsupported in the Data Fitting component, use the extended version of the routine df?interpolateex1d. With this routine, you can provide user-defined callback functions for computations within, to the left of, or to the right of interpolaton interval [a, b]. The callback functions compute indices of the cells that contain the specified interpolation sites or can serve as an approximation for computing the exact indices of such cells.

If you do not pass any function for computations at the sites outside the interval [a, b], the routine uses the default settings.

Input Parameters

Name	Type	Description
task	TYPE(DF_TASK)	Descriptor of the task.
method	INTEGER	Integration method. The supported value is DF_METHOD_PP.
nlim	INTEGER	Number of pairs of integration limits.
llim	REAL(KIND=4) DIMENSION(*) for dfsintegrate1d/ dfsintegrateex1d REAL(KIND=8) DIMENSION(*) for dfdintegrate1d/ dfdintegrateex1d	Array of size *nlim* that defines the left-side integration limits.
llimhint	INTEGER	A flag describing the structure of the left-side integration limits *llim*. For the list of possible values of *llimhint*, see table "Hint Values for Integration Limits". If you set the flag to the DF_NO_HINT value, the library assumes that the left-side integration limits define a non-uniform partition.
rlim	REAL(KIND=4) DIMENSION(*) for dfsintegrate1d/ dfsintegrateex1d REAL(KIND=8) DIMENSION(*) for dfdintegrate1d/ dfdintegrateex1d	Array of size *nlim* that defines the right-side integration limits.
rlimhint	INTEGER	A flag describing the structure of the right-side integration limits *rlim*. For the list of possible values of *rlimhint*, see table "Hint Values for Integration Limits". If you set the flag to the DF_NO_HINT value, the library assumes that the right-side integration limits define a non-uniform partition.
ldatahint	REAL(KIND=4) DIMENSION(*) for dfsintegrate1d/ dfsintegrateex1d REAL(KIND=8) DIMENSION(*) for dfdintegrate1d/ dfdintegrateex1d	Array that contains additional information about the structure of partition *x* and left-side integration limits. For details on the *ldatahint* array, see table "Structure of the *datahint* Array" in the description of the df? intepolate1d function.

Name	Type	Description
rdatahint	REAL(KIND=4) DIMENSION(*) for dfsintegrate1d/ dfsintegrateex1d REAL(KIND=8) DIMENSION(*) for dfdintegrate1d/ dfdintegrateex1d	Array that contains additional information about the structure of partition *x* and right-side integration limits. For details on the *rdatahint* array, see table "Structure of the *datahint* Array" in the description of the df? intepolate1d function.
rhint	INTEGER	A flag describing the structure of the results. For the list of possible values of *rhint*, see table "Hint Values for Integration Results". If you set the flag to the DF_NO_HINT value, the library stores the results in row-major format.
le_cb	INTEGER	User-defined callback function for integration on interval [*llim*(*i*), min(*rlim*(*i*), *a*)) for *llim*(*i*) < *a* .
le_params	INTEGER DIMENSION(*)	Pointer to additional user-defined parameters passed by the library to the *le_cb* function.
re_cb	INTEGER	User-defined callback function for integration on interval [max(*llim*(*i*), *b*), *rlim*(*i*)) for *rlim*(*i*) ≥ *b*.
re_params	INTEGER DIMENSION(*)	Pointer to additional user-defined parameters passed by the library to the *re_cb* function.
i_cb	INTEGER	User-defined callback function for integration on interval [max(*a*, *llim*(*i*),), min(*rlim*(*i*), *b*)).
i_params	INTEGER DIMENSION(*)	Pointer to additional user-defined parameters passed by the library to the *i_cb* function.
search_cb	INTEGER	User-defined callback function for computing indices of cells that can contain interpolation sites.
search_params	INTEGER DIMENSION(*)	Pointer to additional user-defined parameters passed by the library to the *search_cb* function.

Output Parameters

Name	Type	Description
status	INTEGER	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Name	Type	Description
r	`REAL(KIND=4) DIMENSION(*)` for `df?integrate1d`/ `df?integrateex1d` `REAL(KIND=8) DIMENSION(*)` for `df?integrate1d`/ `df?integrateex1d`	Array of `integration` results. The size of the array should be sufficient to hold *nlim***ny* values, where *ny* is the dimension of the vector-valued function. The integration results are packed according to the settings in *rhint*.

Description

The `df?integrate1d`/`df?integrateex1d` routine computes spline-based integral on user-defined intervals

$$I(i,j)=\int_{ll_i}^{rl_i} f_j(x)dx$$

,

where rl_i = *rlim*(*i*), ll_i = *llim*(*i*), and *i* = 1, ..., *ny*.

If *rlim*(*i*) < *llim*(*i*), the routine returns

$$I(i,j)=-\int_{rl_i}^{ll_i} f_j(x)dx$$

The routine supports the following hint values for integration results:

Hint Values for Integration Results

Value	Description
`DF_MATRIX_STORAGE_ROWS`	Data is stored in row-major format according to C conventions.
`DF_MATRIX_STORAGE_COLS`	Data is stored in column-major format according to Fortran conventions.
`DF_NO_HINT`	No hint is provided. By default, the coordinates of vector-valued function *y* are provided and stored in row-major format.

A common structure of the storage formats for the integration results is as follows:

- Row-major format

I(1, 1)	...	*I*(1, *nlim*)
...	...	...
I (*ny*, 1)	...	*I*(*ny* , *nlim*)

- Column-major format

I(1, 1)	...	*I* (*ny*, 1)
...	...	...
I(1, *nlim*)	...	*I*(*ny* , *nlim*)

Using the *llimhint* and *rlimhint* parameters, you can provide the following hint values for integration limits:

Hint Values for Integration Limits

Value	Description
DF_SORTED_DATA	Integration limits are sorted in the ascending order and define a non-uniform partition.
DF_NON_UNIFORM_PARTITION	Partition defined by integration limits is non-uniform.
DF_UNIFORM_PARTITION	Partition defined by integration limits is uniform.
DF_NO_HINT	No hint is provided. By default, partition defined by integration limits is interpreted as non-uniform.

To compute integration with splines unsupported in the Data Fitting component, use the extended version of the routine df?integrateex1d. With this routine, you can provide user-defined callback functions that compute:

- integrals within, to the left of, or to the right of the interpolation interval [*a*, *b*]
- indices of cells that contain the provided integration limits or can serve as an approximation for computing the exact indices of such cells

If you do not pass callback functions, the routine uses the default settings.

Searches sub-intervals containing interpolation sites.

Syntax

status = dfssearchcells1d(*task*, *method*, *nsite*, *site*, *sitehint*, *datahint*, *cell*)

status = dfdsearchcells1d(*task*, *method*, *nsite*, *site*, *sitehint*, *datahint*, *cell*)

status = dfssearchcellsex1d(*task*, *method*, *nsite*, *site*, *sitehint*, *datahint*, *cell*, *search_cb*, *search_params*)

status = dfdsearchcellsex1d(*task*, *method*, *nsite*, *site*, *sitehint*, *datahint*, *cell*, *search_cb*, *search_params*)

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
task	TYPE(DF_TASK)	Descriptor of the task.
method	INTEGER	Search method. The supported value is DF_METHOD_STD.

Name	Type	Description
nsite	INTEGER	Number of interpolation sites.
site	REAL(KIND=4) DIMENSION(*) for dfssearchcells1d/ dfssearchcellsex1d REAL(KIND=8) DIMENSION(*) for dfdsearchcells1d/ dfdsearchcellsex1d	Array of interpolation sites of size *nsite*. The structure of the array is defined by the *sitehint* parameter: • If the sites form a non-uniform partition, the array should contain *nsite* values. • If the sites form a uniform partition, the array should contain two entries that represent the left-most and the right-most interpolation sites. The first entry of the array contains the left-most interpolation point. The second entry of the array contains the right-most interpolation point.
sitehint	INTEGER	A flag describing the structure of the interpolation sites. For the list of possible values of *sitehint*, see table "Hint Values for Interpolation Sites". If you set the flag to DF_NO_HINT, the library interprets the site-defined partition as non-uniform.
datahint	REAL(KIND=4) DIMENSION(*) for dfssearchcells1d/ dfssearchcellsex1d REAL(KIND=8) DIMENSION(*) for dfdsearchcells1d/ dfdsearchcellsex1d	Array that contains additional information about the structure of the partition and interpolation sites. This data helps to speed up the computation. If you provide a NULL pointer, the routine uses the default settings for computations. For details on the *datahint* array, see table "Structure of the *datahint* Array".
search_cb	INTEGER	User-defined callback function for computing indices of cells that can contain interpolation sites. Set to NULL if you are not supplying a callback function.
search_params	INTEGER DIMENSION(*)	Pointer to additional user-defined parameters passed by the library to the *search_cb* function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.

Output Parameters

Name	Type	Description
status	INTEGER	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.
cell	INTEGER DIMENSION(*)	Array of cell indices in the partition that contain the interpolation sites.

Description

The df?searchcells1d/df?searchcellsex1d routines return array *cell* of indices of sub-intervals (cells) in the partition that contain interpolation sites available in array *site*. For details on the cell indexing scheme, see the description of the df?interpolate1d/df?interpolateex1d computation routines.

Use the *datahint* parameter to provide additional information about the structure of the partition and/or interpolation sites. The definition of the *datahint* parameter is availalbe in the description of the df?interpolate1d/df?interpolateex1d computation routines.

For description of the user-defined callback for computation of cell indices, see df?searchcellscallback.

df?integrcallback

A callback function that you can pass into df?integrateex1d *to define integration computations.*

Syntax

status = dfsintegrcallback(*n*, *lcell*, *llim*, *rcell*, *rlim*, *r*, *user_params*, *library_params*)

status = dfdintegrcallback(*n*, *lcell*, *llim*, *rcell*, *rlim*, *r*, *user_params*, *library_params*)

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
n	INTEGER(KIND=8)	Number of pairs of integration limits.
lcell	INTEGER(KIND=8) DIMENSION(*)	Array of size *n* with indices of the cells that contain the left-side integration limits in array *llim*.
llim	REAL(KIND=4) DIMENSION(*) for dfsintegrcallback	Array of size *n* that holds the left-side integration limits.

Name	Type	Description
	`REAL(KIND=8) DIMENSION(*)` for `dfdintegrcallback`	
rcell	`INTEGER(KIND=8) DIMENSION(*)`	Array of size *n* with indices of the cells that contain the right-side integration limits in array *rlim*.
rlim	`REAL(KIND=4) DIMENSION(*)` for `dfsintegrcallback` `REAL(KIND=8) DIMENSION(*)` for `dfdintegrcallback`	Array of size *n* that holds the right-side integration limits.
user_params	`INTEGER DIMENSION(*)`, optional	Pointer to user-defined parameters of the callback function.
library_params	`TYPE(DF_INTEGR_CALLBACK_LIBRARY_PARAMS)`, optional	Pointer to library-defined parameters of the callback function.

Output Parameters

Name	Type	Description
status	`INTEGER`	The status returned by the callback function: • Zero indicates successful completion of the callback operation. • A negative value indicates an error. • A positive value indicates a warning. See "Task Status and Error Reporting" for error code definitions.
r	`REAL(KIND=4) DIMENSION(*)` for `dfsintegrcallback` `REAL(KIND=8) DIMENSION(*)` for `dfdintegrcallback`	Array of integration results. For packing the results in row-major format, follow the instructions described in `df?interpolate1d/df?interpolateex1d`.

Description

When passed into the `df?integrateex1d` routine, this function defines integration computations. If at least one of the integration limits is outside the interpolation interval [*a*, *b*], the library decomposes the integration into sub-intervals that belong to the extrapolation range to the left of *a*, the extrapolation range to the right of *b*, and the interpolation interval [*a*, *b*], as follows:

- If the left integration limit is to the left of the interpolation interval (*llim*< *a*), the `df?integrateex1d` routine passes *llim* as the left integration limit and `min`(*rlim*, *a*) as the right integration limit to the user-defined callback function.
- If the right integration limit is to the right of the interpolation interval (*rlim*> *b*), the `df?integrateex1d` routine passes `max`(*llim*, *b*) as the left integration limit and *rlim* as the right integration limit to the user-defined callback function.
- If the left and the right integration limits belong to the interpolation interval, the `df?integrateex1d` routine passes them to the user-defined callback function unchanged.

The value of the integral is the sum of integral values obtained on the sub-intervals.

The *library_params* parameter allows the library to provide extra parameters, which the callback function can use to organize computations effectively. Currently no parameters are provided.

Syntax

status = dfssearchcellscallback(*n*, *site*, *cell*, *flag*, *user_params*, *library_params*)

status = dfdsearchcellscallback(*n*, *site*, *cell*, *flag*, *user_params*, *library_params*)

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
n	INTEGER(KIND=8)	Number of interpolation sites or integration limits.
site	REAL(KIND=4) DIMENSION(*) for dfssearchcellscallback REAL(KIND=8) DIMENSION(*) for dfdsearchcellscallback	Array, size *n*, of interpolation sites or integration limits.
flag	INTEGER(KIND=4) DIMENSION(*)	Array of size *n*, with values set as follows: • If the cell with index *cell(i)* contains *site(i)*, set *flag*[*i*] to 1. • Otherwise, set *flag(i)* to zero. In this case, the library interprets the index as an approximation and computes the index of the cell containing *site(i)* by using the provided index as a starting point for the search.
user_params	INTEGER DIMENSION(*), optional	Pointer to user-defined parameters of the callback function.

Name	Type	Description
library_params	TYPE(DF_SEARCH_CALLBACK_LIBRARY_PARAMS), optional	Pointer to library-defined parameters of the callback function.

Output Parameters

Name	Type	Description
status	INTEGER	The status returned by the callback function: • Zero indicates successful completion of the callback operation. • A negative value indicates an error. • The DF_STATUS_EXACT_RESULT status indicates that cell indices returned by the callback function are exact. In this case, you do not need to initialize entries of the *flag* array. • A positive value indicates a warning. See "Task Status and Error Reporting" for error code definitions.
cell	INTEGER(KIND=8) DIMENSION(*)	Array of size *n* that returns indices of the cells computed by the callback function.

Description

When passed into the df?interpolateex1d, df?integrateex1d, or df?searchcellsex1d routine, this function performs a user-defined search.

The *library_params* parameter allows the library to provide extra parameters, which the callback function can use to organize computations effectively. The df?interpolateex1d, and df?searchcellsex1d routines do not provide extra parameters. The df?integrateex1d routines use this parameter to specify which type of integration limits, left or right, are provided for the callback. To do this the library declares the DF_SEARCH_CALLBACK_LIBRARY_PARAMS derived type. It currently contains one component, limit_type_flag, of type INTEGER(KIND=4). The field is set by the library to one of two possible values: DF_INTEGR_SEARCH_CB_LLIM_FLAG if the left integration limits are provided, or DF_INTEGR_SEARCH_CB_RLIM_FLAG if the right integration limits are provided.

Data Fitting Task Destructors

Task destructors are routines used to delete task descriptors and deallocate the corresponding memory resources. The Data Fitting task destructor dfdeletetask destroys a Data Fitting task and frees the memory.

dfdeletetask

Destroys a Data Fitting task object and frees the memory.

Syntax

```
status = dfdeletetask(task)
```

Include Files

- mkl_df.f90

Input Parameters

Name	Type	Description
task	TYPE(DF_TASK)	Descriptor of the task to destroy.

Output Parameters

Name	Type	Description
status	INTEGER	Status of the routine: • DF_STATUS_OK if the task is deleted successfully. • Non-zero error code if the operation failed. See "Task Status and Error Reporting" for error code definitions.

Description

Given a pointer to a task descriptor, this routine deletes the Data Fitting task descriptor and frees the memory allocated for the structure. If the task is deleted successfully, the routine sets the task pointer to NULL. Otherwise, the routine returns an error code.

Appendix A: Linear Solvers Basics

Many applications in science and engineering require the solution of a system of linear equations. This problem is usually expressed mathematically by the matrix-vector equation, $Ax = b$, where A is an m-by-n matrix, x is the n element column vector and b is the m element column vector. The matrix A is usually referred to as the coefficient matrix, and the vectors x and b are referred to as the solution vector and the right-hand side, respectively.

Basic concepts related to solving linear systems with sparse matrices are described in Sparse Linear Systems and various storage schemes for sparse matrices are described in Sparse Matrix Storage Formats.

Sparse Linear Systems

In many real-life applications, most of the elements in A are zero. Such a matrix is referred to as sparse. Conversely, matrices with very few zero elements are called dense. For sparse matrices, computing the solution to the equation $Ax = b$ can be made much more efficient with respect to both storage and computation time, if the sparsity of the matrix can be exploited. The more an algorithm can exploit the sparsity without sacrificing the correctness, the better the algorithm.

Generally speaking, computer software that finds solutions to systems of linear equations is called a solver. A solver designed to work specifically on sparse systems of equations is called a sparse solver. Solvers are usually classified into two groups - direct and iterative.

Iterative Solvers start with an initial approximation to a solution and attempt to estimate the difference between the approximation and the true result. Based on the difference, an iterative solver calculates a new approximation that is closer to the true result than the initial approximation. This process is repeated until the difference between the approximation and the true result is sufficiently small. The main drawback to iterative solvers is that the rate of convergence depends greatly on the values in the matrix *A*. Consequently, it is not possible to predict how long it will take for an iterative solver to produce a solution. In fact, for ill-conditioned matrices, the iterative process will not converge to a solution at all. However, for well-conditioned matrices it is possible for iterative solvers to converge to a solution very quickly. Consequently, if an application involves well-conditioned matrices iterative solvers can be very efficient.

Direct Solvers, on the other hand, factor the matrix *A* into the product of two triangular matrices and then perform a forward and backward triangular solve.

This approach makes the time required to solve a systems of linear equations relatively predictable, based on the size of the matrix. In fact, for sparse matrices, the solution time can be predicted based on the number of non-zero elements in the array *A*.

Matrix Fundamentals

A matrix is a rectangular array of either real or complex numbers. A matrix is denoted by a capital letter; its elements are denoted by the same lower case letter with row/column subscripts. Thus, the value of the element in row *i* and column *j* in matrix *A* is denoted by `a(i,j)`. For example, a 3 by 4 matrix *A*, is written as follows:

$$A = \begin{bmatrix} a(1,1) & a(1,2) & a(1,3) & a(1,4) \\ a(2,1) & a(2,2) & a(2,3) & a(2,4) \\ a(3,1) & a(3,2) & a(3,3) & a(3,4) \end{bmatrix}$$

Note that with the above notation, we assume the standard Fortran programming language convention of starting array indices at 1 rather than the C programming language convention of starting them at 0.

A matrix in which all of the elements are real numbers is called a real matrix. A matrix that contains at least one complex number is called a complex matrix. A real or complex matrix *A* with the property that *a*(*i*,*j*) = *a*(*j*,*i*), is called a symmetric matrix. A complex matrix *A* with the property that *a*(*i*,*j*) = *conj*(*a*(*j*,*i*)), is called a Hermitian matrix. Note that programs that manipulate symmetric and Hermitian matrices need only store half of the matrix values, since the values of the non-stored elements can be quickly reconstructed from the stored values.

A matrix that has the same number of rows as it has columns is referred to as a square matrix. The elements in a square matrix that have same row index and column index are called the diagonal elements of the matrix, or simply the diagonal of the matrix.

The transpose of a matrix *A* is the matrix obtained by "flipping" the elements of the array about its diagonal. That is, we exchange the elements `a(i,j)` and `a(j,i)`. For a complex matrix, if we both flip the elements about the diagonal and then take the complex conjugate of the element, the resulting matrix is called the Hermitian transpose or conjugate transpose of the original matrix. The transpose and Hermitian transpose of a matrix *A* are denoted by A^T and A^H respectively.

A column vector, or simply a vector, is a $n \times 1$ matrix, and a row vector is a $1 \times n$ matrix. A real or complex matrix *A* is said to be positive definite if the vector-matrix product x^TAx is greater than zero for all non-zero vectors *x*. A matrix that is not positive definite is referred to as indefinite.

An upper (or lower) triangular matrix, is a square matrix in which all elements below (or above) the diagonal are zero. A unit triangular matrix is an upper or lower triangular matrix with all 1's along the diagonal.

A matrix P is called a permutation matrix if, for any matrix A, the result of the matrix product PA is identical to A except for interchanging the rows of A. For a square matrix, it can be shown that if PA is a permutation of the rows of A, then AP^T is the same permutation of the columns of A. Additionally, it can be shown that the inverse of P is P^T.

In order to save space, a permutation matrix is usually stored as a linear array, called a permutation vector, rather than as an array. Specifically, if the permutation matrix maps the i-th row of a matrix to the j-th row, then the i-th element of the permutation vector is j.

A matrix with non-zero elements only on the diagonal is called a diagonal matrix. As is the case with a permutation matrix, it is usually stored as a vector of values, rather than as a matrix.

Direct Method

For solvers that use the direct method, the basic technique employed in finding the solution of the system $Ax = b$ is to first factor A into triangular matrices. That is, find a lower triangular matrix L and an upper triangular matrix U, such that $A = LU$. Having obtained such a factorization (usually referred to as an LU decomposition or LU factorization), the solution to the original problem can be rewritten as follows.

$$Ax = b$$
$$\Rightarrow \quad LUx = b$$
$$\Rightarrow \quad L(Ux) = b$$

This leads to the following two-step process for finding the solution to the original system of equations:

1. Solve the systems of equations $Ly = b$.
2. Solve the system $Ux = y$.

Solving the systems $Ly = b$ and $Ux = y$ is referred to as a forward solve and a backward solve, respectively.

If a symmetric matrix A is also positive definite, it can be shown that A can be factored as LL^T where L is a lower triangular matrix. Similarly, a Hermitian matrix, A, that is positive definite can be factored as $A = LL^H$. For both symmetric and Hermitian matrices, a factorization of this form is called a Cholesky factorization.

In a Cholesky factorization, the matrix U in an LU decomposition is either L^T or L^H. Consequently, a solver can increase its efficiency by only storing L, and one-half of A, and not computing U. Therefore, users who can express their application as the solution of a system of positive definite equations will gain a significant performance improvement over using a general representation.

For matrices that are symmetric (or Hermitian) but not positive definite, there are still some significant efficiencies to be had. It can be shown that if A is symmetric but not positive definite, then A can be factored as $A = LDL^T$, where D is a diagonal matrix and L is a lower unit triangular matrix. Similarly, if A is Hermitian, it can be factored as $A = LDL^H$. In either case, we again only need to store L, D, and half of A and we need not compute U. However, the backward solve phases must be amended to solving $L^Tx = D^{-1}y$ rather than $L^Tx = y$.

Fill-In and Reordering of Sparse Matrices

Two important concepts associated with the solution of sparse systems of equations are fill-in and reordering. The following example illustrates these concepts.

Consider the system of linear equation $Ax = b$, where A is a symmetric positive definite sparse matrix, and A and b are defined by the following:

$$A = \begin{bmatrix} 9 & \frac{3}{2} & 6 & \frac{3}{4} & 3 \\ \frac{3}{2} & \frac{1}{2} & \star & \star & \star \\ 6 & \star & 12 & \star & \star \\ \frac{3}{4} & \star & \star & \frac{5}{8} & \star \\ 3 & \star & \star & \star & 16 \end{bmatrix}, b = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

A star (*) is used to represent zeros and to emphasize the sparsity of *A*. The Cholesky factorization of *A* is: $A = LL^T$, where *L* is the following:

$$L = \begin{bmatrix} 3 & * & * & * & * \\ \frac{1}{2} & \frac{1}{2} & * & * & * \\ 2 & -2 & 2 & * & * \\ \frac{1}{4} & \frac{1}{-4} & \frac{1}{-2} & \frac{1}{2} & * \\ 1 & -1 & -2 & -3 & 1 \end{bmatrix}$$

Notice that even though the matrix *A* is relatively sparse, the lower triangular matrix *L* has no zeros below the diagonal. If we computed *L* and then used it for the forward and backward solve phase, we would do as much computation as if *A* had been dense.

The situation of *L* having non-zeros in places where *A* has zeros is referred to as fill-in. Computationally, it would be more efficient if a solver could exploit the non-zero structure of *A* in such a way as to reduce the fill-in when computing *L*. By doing this, the solver would only need to compute the non-zero entries in *L*. Toward this end, consider permuting the rows and columns of *A*. As described in Matrix Fundamentals, the permutations of the rows of *A* can be represented as a permutation matrix, *P*. The result of permuting the rows is the product of *P* and *A*. Suppose, in the above example, we swap the first and fifth row of *A*, then swap the first and fifth columns of *A*, and call the resulting matrix *B*. Mathematically, we can express the process of permuting the rows and columns of *A* to get *B* as $B = PAP^T$. After permuting the rows and columns of *A*, we see that *B* is given by the following:

$$B = \begin{bmatrix} 16 & * & * & * & 3 \\ * & \frac{1}{2} & * & * & \frac{3}{2} \\ * & * & 12 & * & 6 \\ * & * & * & \frac{5}{8} & \frac{3}{4} \\ 3 & \frac{3}{2} & 6 & \frac{3}{4} & 9 \end{bmatrix}$$

Since *B* is obtained from *A* by simply switching rows and columns, the numbers of non-zero entries in *A* and *B* are the same. However, when we find the Cholesky factorization, $B = LL^T$, we see the following:

$$L = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{\frac{3}{5}}}{4} \end{bmatrix}$$

The fill-in associated with *B* is much smaller than the fill-in associated with *A*. Consequently, the storage and computation time needed to factor *B* is much smaller than to factor *A*. Based on this, we see that an efficient sparse solver needs to find permutation *P* of the matrix *A*, which minimizes the fill-in for factoring $B = PAP^T$, and then use the factorization of *B* to solve the original system of equations.

Although the above example is based on a symmetric positive definite matrix and a Cholesky decomposition, the same approach works for a general *LU* decomposition. Specifically, let *P* be a permutation matrix, $B = PAP^T$ and suppose that *B* can be factored as $B = LU$. Then

$$Ax = b$$

$$\Rightarrow$$

$$PA(P^{-1}P)x = Pb$$

$$\Rightarrow$$

$$PA(P^TP)x = Pb$$

$$\Rightarrow$$

$$(PAP^T)(Px) = Pb$$

$$\Rightarrow$$

$$B(Px) = Pb$$

$$\Rightarrow$$

$$LU(Px) = Pb$$

It follows that if we obtain an *LU* factorization for *B*, we can solve the original system of equations by a three step process:

1. Solve $Ly = Pb$.
2. Solve $Uz = y$.
3. Set $x = P^T z$.

If we apply this three-step process to the current example, we first need to perform the forward solve of the systems of equation $Ly = Pb$:

$$Ly = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{\frac{3}{5}}}{4} \end{bmatrix} * \begin{bmatrix} y1 \\ y2 \\ y3 \\ y4 \\ y5 \end{bmatrix} = \begin{bmatrix} 5 \\ 2 \\ 3 \\ 4 \\ 1 \end{bmatrix}$$

This gives:

$$y^T = \frac{5}{4}, 2\sqrt{2}, \frac{\sqrt{3}}{2}, \frac{16}{\sqrt{10}}, \frac{-979\sqrt{\frac{3}{5}}}{12}.$$

The second step is to perform the backward solve, $Uz = y$. Or, in this case, since a Cholesky factorization is used, $L^T z = y$.

$$\begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{\frac{3}{5}}}{4} \end{bmatrix}^T * \begin{bmatrix} z1 \\ z2 \\ z3 \\ z4 \\ z5 \end{bmatrix} = \begin{bmatrix} \frac{5}{4} \\ 2(\sqrt{2}) \\ \frac{\sqrt{3}}{2} \\ \frac{16}{\sqrt{10}} \\ \frac{-979\sqrt{\frac{3}{5}}}{12} \end{bmatrix}$$

This gives

$$z^T = \frac{123}{2}, 983, \frac{1961}{12}, 398, \frac{-979}{3}.$$

The third and final step is to set $x = P^T z$. This gives

$$x^T = \frac{-979}{3}, 983, \frac{1961}{12}, 398, \frac{123}{2}.$$

Sparse Matrix Storage Formats

It is more efficient to store only the non-zero elements of a sparse matrix. There are a number of common storage formats used for sparse matrices, but most of them employ the same basic technique. That is, store all non-zero elements of the matrix into a linear array and provide auxiliary arrays to describe the locations of the non-zero elements in the original matrix.

Storage Formats for the Direct Sparse Solvers

Storing the non-zero elements of a sparse matrix into a linear array is done by walking down each column (column-major format) or across each row (row-major format) in order, and writing the non-zero elements to a linear array in the order they appear in the walk.

Sparse Matrix Storage Formats for Sparse BLAS Levels 2 and Level 3

These sections describe in detail the sparse matrix storage formats supported in the current version of the Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS Level 2 and Level 3.

- Sparse BLAS CSR Matrix Storage
- Sparse BLAS CSC Matrix Storage
- Sparse BLAS Coordinate Matrix Storage
- Sparse BLAS Diagonal Matrix Storage
- Sparse BLAS Skyline Matrix Storage
- Sparse BLAS BSR Matrix Storage

DSS Symmetric Matrix Storage

For symmetric matrices, it is necessary to store only the upper triangular half of the matrix (upper triangular format) or the lower triangular half of the matrix (lower triangular format).

The Intel® oneAPI Math Kernel Library (oneMKL) direct sparse solvers use a row-major upper triangular storage format: the matrix is compressed row-by-row and for symmetric matrices only non-zero elements in the upper triangular half of the matrix are stored.

The Intel® oneAPI Math Kernel Library (oneMKL) sparse matrix storage format for direct sparse solvers is specified by three arrays:*values*, *columns*, and *rowIndex*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix.

values	A real or complex array that contains the non-zero elements of a sparse matrix. The non-zero elements are mapped into the *values* array using the row-major upper triangular storage mapping described above.
columns	Element *i* of the integer array *columns* is the number of the column that contains the *i*-th element in the *values* array.
rowIndex	Element *j* of the integer array *rowIndex* gives the index of the element in the *values* array that is first non-zero element in a row *j*.

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in the matrix.

As the *rowIndex* array gives the location of the first non-zero element within a row, and the non-zero elements are stored consecutively, the number of non-zero elements in the *i*-th row is equal to the difference of `rowIndex(i)` and `rowIndex(i+1)`.

To have this relationship hold for the last row of the matrix, an additional entry (dummy entry) is added to the end of *rowIndex*. Its value is equal to the number of non-zero elements plus one. This makes the total length of the *rowIndex* array one larger than the number of rows in the matrix.

NOTE
The Intel® oneAPI Math Kernel Library (oneMKL) sparse storage scheme for the direct sparse solvers supports both one-based indexing and zero-based indexing.

Consider the symmetric matrix *A*:

$$A = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -3 & * & 6 & 7 & * \\ * & * & 4 & * & -5 \end{pmatrix}$$

Only elements from the upper triangle are stored. The actual arrays for the matrix *A* are as follows:

Storage Arrays for a Symmetric Matrix

one-based indexing									
values	=	(1	-1	-3	5	4	6	4	7	-5)
columns	=	(1	2	4	2	3	4	5	4	5)
rowIndex	=	(1	4	5	8	9	10)			
zero-based indexing										

values	=	(1	-1	-3	5	4	6	4	7	-5)
columns	=	(0	1	3	1	2	3	4	3	4)
rowIndex	=	(0	3	4	7	8	9)			

Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

DSS Nonsymmetric Matrix Storage

For a non-symmetric or non-Hermitian matrix, all non-zero elements need to be stored. Consider the non-symmetric matrix *B*:

$$\begin{pmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{pmatrix}$$

The matrix *B* has 13 non-zero elements, and all of them are stored as follows:

Storage Arrays for a Non-Symmetric Matrix

one-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
rowIndex	=	(1	4	6	9	12	14)							
zero-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
rowIndex	=	(0	3	5	8	11	13)							

Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

DSS Structurally Symmetric Matrix Storage

Direct sparse solvers can also solve symmetrically structured systems of equations. A symmetrically structured system of equations is one where the pattern of non-zero elements is symmetric. That is, a matrix has a symmetric structure if $a_{j,i}$ is not zero if and only if $a_{i,j}$ is not zero. From the point of view of the solver software, a "non-zero" element of a matrix is any element stored in the *values* array, even if its value is

equal to 0. In that sense, any non-symmetric matrix can be turned into a symmetrically structured matrix by carefully adding zeros to the *values* array. For example, the above matrix *B* can be turned into a symmetrically structured matrix by adding two non-zero entries:

$$B = \begin{pmatrix} 1 & -1 & * & 3 & * \\ -2 & 5 & * & * & 0 \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & 0 & * & -5 \end{pmatrix}$$

The matrix *B* can be considered to be symmetrically structured with 15 non-zero elements and represented as:

Storage Arrays for a Symmetrically Structured Matrix

one-based indexing															
values	=	(1	-1	-3	-2	5	0	4	6	4	-4	2	7	8	0	-5)
columns	=	(1	2	4	1	2	5	3	4	5	1	3	4	2	3	5)
rowIndex	=	(1	4	7	10	13	16)									
zero-based indexing																
values	=	(1	-1	-3	-2	5	0	4	6	4	-4	2	7	8	0	-5)
columns	=	(0	1	3	0	1	4	2	3	4	0	2	3	1	2	4)
rowIndex	=	(0	3	6	9	12	15)									

Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

DSS Distributed Symmetric Matrix Storage

The distributed assembled matrix input format can be used by the Parallel Direct Sparse Solver for Clusters Interface.

In this format, the symmetric input matrix *A* is divided into sequential row subsets, or domains. Each domain belongs to an MPI process. Neighboring domains can overlap. For such intersection between two domains, the element values of the full matrix can be obtained by summing the respective elements of both domains.

As in the centralized format, the distributed format uses three arrays to describe the input data, but the *values*, *columns*, and *rowIndex* arrays on each processor only describe the domain belonging to that particular processor and not the entire matrix.

For example, consider a symmetric matrix *A*:

$$A = \begin{pmatrix} \mathbf{6} & \mathbf{-1} & * & \mathbf{-3} & * \\ \mathbf{-1} & \mathbf{5} & * & * & * \\ * & * & \mathbf{11} & \mathbf{5} & \mathbf{4} \\ -3 & * & 5 & \mathbf{10} & * \\ * & * & 4 & * & \mathbf{5} \end{pmatrix}$$

This array could be distributed between two domains corresponding to two MPI processes, with the first containing rows 1 through 3, and the second containing rows 3 through 5.

NOTE
For the symmetric input matrix, it is not necessary to store the values from the lower triangle.

$$A_{Domain1} = \begin{pmatrix} \mathbf{6} & \mathbf{-1} & * & \mathbf{-3} & * \\ \mathbf{-1} & \mathbf{5} & * & * & * \\ * & * & \mathbf{3} & * & \mathbf{2} \end{pmatrix}$$

Distributed Storage Arrays for a Symmetric Matrix, Domain 1

one-based indexing							
values	=	(6	-1	-3	5	3	2)
columns	=	(1	2	4	2	3	5)
rowIndex	=	(1	4	5	7)		
zero-based indexing							
values	=	(6	-1	-3	5	3	2)
columns	=	(0	1	3	1	2	4)
rowIndex	=	(0	3	4	6)		

$$A_{Domain2} = \begin{pmatrix} * & * & \mathbf{8} & \mathbf{5} & \mathbf{2} \\ \mathbf{-3} & * & \mathbf{5} & \mathbf{10} & * \\ * & * & \mathbf{4} & * & \mathbf{5} \end{pmatrix}$$

Distributed Storage Arrays for a Symmetric Matrix, Domain 2

one-based indexing						
values	=	(8	5	2	10	5)
columns	=	(3	4	5	4	5)
rowIndex	=	(1	4	5	6)	
zero-based indexing						
values	=	(8	5	2	10	5)
columns	=	(2	3	4	3	4)
rowIndex	=	(0	3	4	5)	

The third row of matrix *A* is common between domain 1 and domain 2. The values of row 3 of matrix *A* are the sums of the respective elements of row 3 of matrix $A_{Domain1}$ and row 1 of matrix $A_{Domain2}$.

Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

Sparse BLAS CSR Matrix Storage Format

The Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS compressed sparse row (CSR) format is specified by four arrays:

- *values*

- *columns*
- *pointerB*
- *pointerE*

In addition, each sparse matrix has an associated variable ,*indexing*, which specifies if the matrix indices are 0-based (*indexing*=0) or 1-based (*indexing*=1). These are descriptions of the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

values	A real or complex array that contains the non-zero elements of *A*. Values of the non-zero elements of *A* are mapped into the *values* array using the row-major storage mapping described above.
columns	Element *i* of the integer array *columns* is the number of the column in *A* that contains the *i*-th value in the *values* array.
pointerB	Element *j* of this integer array gives the index of the element in the *values* array that is first non-zero element in a row *j* of *A*. Note that this index is equal to *pointerB(j) - indexing* .
pointerE	An integer array that contains row indices, such that *pointerE(j)-indexing* is the index of the element in the *values* array that is last non-zero element in a row *j* of *A*.

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*.The length of the *pointerB* and *pointerE* arrays is equal to the number of rows in *A*.

NOTE
Note that the Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS routines support the CSR format both with one-based indexing and zero-based indexing.

You can represent the matrix *B*

$$B = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{pmatrix}$$

in the CSR format as:

Storage Arrays for a Matrix in CSR Format

one-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
pointerB	=	(1	4	6	9	12)								
pointerE	=	(4	6	9	12	14)								
zero-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
pointerB	=	(0	3	5	8	11)								
pointerE	=	(3	5	8	11	13)								

Additionally, you can define submatrices with different *pointerB* and *pointerE* arrays that share the same *values* and *columns* arrays of a CSR matrix. For example, you can represent the lower right 3x3 submatrix of *B* as:

Storage Arrays for a Matrix in CSR Format

one-based indexing				
subpointerB	=	(6	10	13)
subpointerE	=	(9	12	14)
zero-based indexing				

subpointerB	=	(5	9	12)
subpointerE	=	(8	11	13)

NOTE The CSR matrix must have a monotonically increasing row index. That is, *pointerB[i]* ≤ *pointerB[j]* and *pointerE[i]* ≤ *pointerE[j]* for all indices *i* <*j*.

This storage format is used in the NIST Sparse BLAS library [Rem05].

Three Array Variation of CSR Format

The storage format accepted for the direct sparse solvers is a variation of the CSR format. It also is used in the Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS Level 2 both with one-based indexing and zero-based indexing. The above matrix*B* can be represented in this format (referred to as the 3-array variation of the CSR format or CSR3) as:

Storage Arrays for a Matrix in CSR Format (3-Array Variation)

one-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
rowIndex	=	(1	4	6	9	12	14)							
zero-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
rowIndex	=	(0	3	5	8	11	13)							

The 3-array variation of the CSR format has a restriction: all non-zero elements are stored continuously, that is the set of non-zero elements in the row *J* goes just after the set of non-zero elements in the row *J–1*.

There are no such restrictions in the general (NIST) CSR format. This may be useful, for example, if there is a need to operate with different submatrices of the matrix at the same time. In this case, it is enough to define the arrays *pointerB* and *pointerE* for each needed submatrix so that all these arrays are pointers to the same array *values*.

By definition, the array *rowIndex* from the Table "Storage Arrays for a Non-Symmetric Example Matrix" is related to the arrays *pointerB* and *pointerE* from the Table "Storage Arrays for an Example Matrix in CSR Format", and you can see that

```
pointerB(i) = rowIndex(i) for i=1, ..5;
              pointerE(i) = rowIndex(i+1) for i=1, ..5.
```

This enables calling a routine that has *values*, *columns*, *pointerB* and *pointerE* as input parameters for a sparse matrix stored in the format accepted for the direct sparse solvers. For example, a routine with the interface:

```
   Subroutine name_routine(.... ,  values, columns, pointerB, pointerE, ...)
```

can be called with parameters *values*, *columns*, *rowIndex* as follows:

```
   call name_routine(.... ,  values, columns, rowIndex, rowIndex(2), ...).
```

Sparse BLAS CSC Matrix Storage Format

The compressed sparse column format (CSC) is similar to the CSR format, but the columns are used instead the rows. In other words, the CSC format is identical to the CSR format for the transposed matrix. The CSR format is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

values A real or complex array that contains the non-zero elements of *A*. Values of the non-zero elements of *A* are mapped into the *values* array using the column-major storage mapping.

rows Element *i* of the integer array *rows* is the number of the row in *A* that contains the *i*-th value in the *values* array.

pointerB Element *j* of this integer array gives the index of the element in the *values* array that is first non-zero element in a column *j* of *A*. Note that this index is equal to `pointerB(j)-indexing` for Inspector-executor Sparse BLAS CSC arrays.

pointerE An integer array that contains column indices, such that `pointerE(j)-indexing` is the index of the element in the *values* array that is last non-zero element in a column *j* of *A*.

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*. The length of the *pointerB* and *pointerE* arrays is equal to the number of columns in *A*.

NOTE
Note that the Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS routines support the CSC format both with one-based indexing and zero-based indexing.

For example, consider matrix *B*:

$$B = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{pmatrix}$$

It can be represented in the CSC format as:

Storage Arrays for a Matrix in CSC Format

one-based indexing													
values	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
rows	=	(1	2	4	1	2	5	3	4	1	3	4	3	5)
pointerB	=	(1	4	7	9	12)								
pointerE	=	(4	7	9	12	14)								
zero-based indexing													
values	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
rows	=	(0	1	3	0	1	4	2	3	0	2	3	2	4)
pointerB	=	(0	3	6	8	11)								
pointerE	=	(3	6	8	11	13)								

Sparse BLAS Coordinate Matrix Storage Format

The coordinate format is the most flexible and simplest format for the sparse matrix representation. Only non-zero elements are stored, and the coordinates of each non-zero element are given explicitly. Many commercial libraries support the matrix-vector multiplication for the sparse matrices in the coordinate format.

The Intel® oneAPI Math Kernel Library (oneMKL) coordinate format is specified by three arrays:*values*, *rows*, and *column*, and a parameter *nnz* which is number of non-zero elements in *A*. All three arrays have dimension *nnz*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

values A real or complex array that contains the non-zero elements of *A* in any order.

rows Element *i* of the integer array *rows* is the number of the row in *A* that contains the *i*-th value in the *values* array.

columns Element *i* of the integer array *columns* is the number of the column in *A* that contains the *i*-th value in the *values* array.

NOTE
Note that the Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS routines support the coordinate format both with one-based indexing and zero-based indexing.

For example, the sparse matrix *C*

$$C = \begin{pmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{pmatrix}$$

can be represented in the coordinate format as follows:

Storage Arrays for an Example Matrix in case of the coordinate format

one-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
rows	=	(1	1	1	2	2	3	3	3	4	4	4	5	5)
columns	=	(1	2	3	1	2	3	4	5	1	3	4	2	5)
zero-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
rows	=	(0	0	0	1	1	2	2	2	3	3	3	4	4)
columns	=	(0	1	2	0	1	2	3	4	0	2	3	1	4)

Sparse BLAS Diagonal Matrix Storage Format

If the sparse matrix has diagonals containing only zero elements, then the diagonal storage format can be used to reduce the amount of information needed to locate the non-zero elements. This storage format is particularly useful in many applications where the matrix arises from a finite element or finite difference discretization. The Intel® oneAPI Math Kernel Library (oneMKL) diagonal storage format is specified by two arrays:*values* and *distance*, and two parameters: *ndiag*, which is the number of non-empty diagonals, and *lval*, which is the declared leading dimension in the calling (sub)programs. The following table describes the arrays *values* and *distance*:

values A real or complex two-dimensional array is dimensioned as *lval* by *ndiag*. Each column of it contains the non-zero elements of certain diagonal of *A*. The key point of the storage is that each element in *values* retains the row number of the original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom. Note that the value of *distance*(*i*) is the number of elements to be padded for diagonal *i*.

distance An integer array with dimension *ndiag*. Element *i* of the array *distance* is the distance between *i*-diagonal and the main diagonal. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero.

The above matrix *C* can be represented in the diagonal storage format as follows:

$$distance = (-3\ -1\ 0\ 1\ 2)$$

$$values = \begin{pmatrix} * & * & 1 & -1 & -3 \\ * & -2 & 5 & 0 & 0 \\ * & 0 & 4 & 6 & 4 \\ -4 & 2 & 7 & 0 & * \\ 8 & 0 & -5 & * & * \end{pmatrix}$$

where the asterisks denote padded elements.

When storing symmetric, Hermitian, or skew-symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For the Intel® oneAPI Math Kernel Library (oneMKL) triangular solver routines elements of the array*distance* must be sorted in increasing order. In all other cases the diagonals and distances can be stored in arbitrary order.

Sparse BLAS Skyline Matrix Storage Format

The skyline storage format is important for the direct sparse solvers, and it is well suited for Cholesky or LU decomposition when no pivoting is required.

The skyline storage format accepted in Intel® oneAPI Math Kernel Library (oneMKL) can store only triangular matrix or triangular part of a matrix. This format is specified by two arrays:*values* and *pointers*. The following table describes these arrays:

values	A scalar array. For a lower triangular matrix it contains the set of elements from each row of the matrix starting from the first non-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets.
pointers	An integer array with dimension `(m+1)`, where *m* is the number of rows for lower triangle (columns for the upper triangle). `pointers(i) - pointers(1)+1` gives the index of element in *values* that is first non-zero element in row (column) *i*. The value of `pointers(m+1)` is set to `nnz+pointers(1)`, where *nnz* is the number of elements in the array *values*.

For example, consider the matrix *C*:

$$C = \begin{pmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{pmatrix}$$

The low triangle of the matrix *C* given above can be stored as follows:

```
values  =  ( 1  -2   5   4  -4   0   2   7   8   0   0   -5 )
                pointers = ( 1   2   4   5   9   13 )
```

and the upper triangle of this matrix *C* can be stored as follows:

```
values   = ( 1  -1   5  -3   0   4   6   7  4   0   -5 )
                pointers = ( 1   2   4   7   9   12 )
```

This storage format is supported by the NIST Sparse BLAS library [Rem05].

Note that the Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS routines operating with the skyline storage format do not support general matrices.

Sparse BLAS BSR Matrix Storage Format

The Intel® oneAPI Math Kernel Library (oneMKL) block compressed sparse row (BSR) format for sparse matrices is specified by four arrays:*values*, *columns*, *pointerB*, and *pointerE*. The following table describes these arrays.

values	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block-by-block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them are equal to zero. Within each non-zero block elements are stored in column-major order in the case of one-based indexing, and in row-major order in the case of the zero-based indexing.
columns	Element *i* of the integer array *columns* is the number of the column in the block matrix that contains the *i*-th non-zero block.
pointerB	Element *j* of this integer array gives the index of the element in the *columns* array that is first non-zero block in a row *j* of the block matrix.
pointerE	Element *j* of this integer array gives the index of the element in the *columns* array that contains the last non-zero block in a row *j* of the block matrix plus 1.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks. The length of the *pointerB* and *pointerE* arrays is equal to the number of block rows in the block matrix.

NOTE
Note that the Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS routines support BSR format both with one-based indexing and zero-based indexing.

For example, consider the sparse matrix *D*

$$D = \begin{pmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ * & * & 1 & 4 & * & * \\ * & * & 5 & 1 & * & * \\ * & * & 4 & 3 & 7 & 2 \\ * & * & 0 & 0 & 0 & 0 \end{pmatrix}$$

If the size of the block equals 2, then the sparse matrix *D* can be represented as a 3x3 block matrix *E* with the following structure:

$$E = \begin{pmatrix} L & M & * \\ * & N & * \\ * & P & Q \end{pmatrix}$$

where

$$L = \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}, M = \begin{pmatrix} 6 & 7 \\ 8 & 2 \end{pmatrix}, N = \begin{pmatrix} 1 & 4 \\ 5 & 1 \end{pmatrix}, P = \begin{pmatrix} 4 & 3 \\ 0 & 0 \end{pmatrix}, Q = \begin{pmatrix} 7 & 2 \\ 0 & 0 \end{pmatrix}$$

The matrix *D* can be represented in the BSR format as follows:

one-based indexing

```
values  =  (1 2 0 1 6 8 7 2 1 5 4 1 4 0 3 0 7 0 2 0)
           columns  = (1   2   2   2   3)
           pointerB = (1   3   4)
           pointerE = (3   4   6)
```

zero-based indexing

```
values  =  [1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0]
           columns  = [0   1   1   1   2]
           pointerB = [0   2   3]
           pointerE = [2   3   5]
```

This storage format is supported by the NIST Sparse BLAS library [Rem05].

Three Array Variation of BSR Format

Intel® oneAPI Math Kernel Library (oneMKL) supports the variation of the BSR format that is specified by three arrays:*values*, *columns*, and *rowIndex*. The following table describes these arrays.

values	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block by block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block the elements are stored in column major order in the case of the one-based indexing, and in row major order in the case of the zero-based indexing.
columns	Element *i* of the integer array *columns* is the number of the column in the block matrix that contains the *i*-th non-zero block.
rowIndex	Element *j* of this integer array gives the index of the element in the *columns* array that is first non-zero block in a row *j* of the block matrix.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks.

As the *rowIndex* array gives the location of the first non-zero block within a row, and the non-zero blocks are stored consecutively, the number of non-zero blocks in the *i*-th row is equal to the difference of `rowIndex(i)` and `rowIndex(i+1)`.

To retain this relationship for the last row of the block matrix, an additional entry (dummy entry) is added to the end of *rowIndex* with value equal to the number of non-zero blocks plus one. This makes the total length of the *rowIndex* array one larger than the number of rows of the block matrix.

The above matrix *D* can be represented in this 3-array variation of the BSR format as follows:

one-based indexing

```
values  =  (1 2 0 1 6 8 7 2 1 5 4 2 4 0 3 0 7 0 2 0)
           columns  = (1   2   2   2   3)
           rowIndex = (1   3   4   6)
```

zero-based indexing

```
values  =  (1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0)
           columns  = (0   1   1   1   2)
           rowIndex = (0   2   3 5)
```

When storing symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For example, consider the symmetric sparse matrix *F*:

$$F = \begin{pmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ 6 & 8 & 1 & 4 & * & * \\ 7 & 2 & 5 & 2 & * & * \\ * & * & * & * & 7 & 2 \\ * & * & * & * & 0 & 0 \end{pmatrix}$$

If the size of the block equals 2, then the sparse matrix *F* can be represented as a 3x3 block matrix *G* with the following structure:

$$G = \begin{pmatrix} L & M & * \\ M' & N & * \\ * & * & Q \end{pmatrix}$$

where

$L = \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}$, $M = \begin{pmatrix} 6 & 7 \\ 8 & 2 \end{pmatrix}$, $M' = \begin{pmatrix} 6 & 8 \\ 7 & 2 \end{pmatrix}$, $N = \begin{pmatrix} 1 & 4 \\ 5 & 2 \end{pmatrix}$, and $Q = \begin{pmatrix} 7 & 2 \\ 0 & 0 \end{pmatrix}$

The symmetric matrix *F* can be represented in this 3-array variation of the BSR format (storing only the upper triangular part) as follows:

one-based indexing

```
values  =  (1 2 0 1 6 8 7 2 1 5 4 2 7 0 2 0)
               columns  = (1   2   2   3)
               rowIndex = (1   3   4 5)
```

zero-based indexing

```
values  =  (1 0 2 1 6 7 8 2 1 4 5 2 7 2 0 0)
               columns  = (0   1   1   2)
               rowIndex = (0   2   3 4)
```

Variable BSR Format

A variation of BSR3 is variable block compressed sparse row format. For a trust level *t*, $0 \le t \le 100$, rows similar up to *t* percent are placed in one supernode.

Appendix B: Routine and Function Arguments

The major arguments in the BLAS routines are vector and matrix, whereas VM functions work on vector arguments only. The sections that follow discuss each of these arguments and provide examples.

Vector Arguments in BLAS

Vector arguments are passed in one-dimensional arrays. The array dimension (length) and vector increment are passed as integer variables. The length determines the number of elements in the vector. The increment (also called stride) determines the spacing between vector elements and the order of the elements in the array in which the vector is passed.

A vector of length *n* and increment *incx* is passed in a one-dimensional array *x* whose values are defined as

```
x(1), x(1+|incx|), ..., x(1+(n-1)* |incx|)
```

If *incx* is positive, then the elements in array *x* are stored in increasing order. If *incx* is negative, the elements in array *x* are stored in decreasing order with the first element defined as `x(1+(n-1)* |incx|)`. If *incx* is zero, then all elements of the vector have the same value, `x(1)`. The size of the one-dimensional array that stores the vector must always be at least

```
idimx = 1 + (n-1)* |incx |
```

Example. One-dimensional Real Array

Let `x(1:7)` be the one-dimensional real array

```
x = (1.0, 3.0, 5.0, 7.0, 9.0, 11.0, 13.0).
```

If `incx =2` and `n = 3`, then the vector argument with elements in order from first to last is `(1.0, 5.0, 9.0)`.

If `incx = -2` and `n = 4`, then the vector elements in order from first to last is `(13.0, 9.0, 5.0, 1.0)`.

If `incx = 0` and `n = 4`, then the vector elements in order from first to last is `(1.0, 1.0, 1.0, 1.0)`.

One-dimensional substructures of a matrix, such as the rows, columns, and diagonals, can be passed as vector arguments with the starting address and increment specified.

In Fortran, storing the `m-by-n` matrix is based on column-major ordering where the increment between elements in the same column is `1`, the increment between elements in the same row is *m*, and the increment between elements on the same diagonal is `m + 1`.

Example. Two-dimensional Real Matrix

Let *a* be a real 5 x 4 matrix declared as `REAL A (5,4)float a[5*4];`.

To scale the third column of *a* by 2.0, use the BLAS routine `sscal` with the following calling sequence:

```
call sscal (5, 2.0, a(1,3), 1)
```

To scale the second row, use the statement:

```
call sscal (4, 2.0, a(2,1), 5)
```

To scale the main diagonal of *a* by 2.0, use the statement:

```
call sscal (5, 2.0, a(1,1), 6)
```

NOTE
The default vector argument is assumed to be 1.

Vector Arguments in Vector Math

Vector arguments of classic VM mathematical functions are passed in one-dimensional arrays with unit vector increment. It means that a vector of length *n* is passed contiguously in an array `a` whose values are defined as

`a(1), a(2), ..., a(n)`

.

Strided VM mathematical functions allow using positive increments for all input and output vector arguments.

To accommodate for arrays with other increments, or more complicated indexing, VM contains auxiliary Pack/Unpack functions that gather the array elements into a contiguous vector and then scatter them after the computation is complete.

Generally, if the vector elements are stored in a one-dimensional array *a* as

```
a(m1), a(m2), ..., a(mn)
```

and need to be regrouped into an array *y* as

```
y(k1), y(k2), ..., y(kn),
```

.

VM Pack/Unpack functions can use one of the following indexing methods:

Positive Increment Indexing

```
kj = 1 + incy * (j - 1), mj = 1 + inca * (j - 1), j = 1, ..., n.
```

.

Constraint: `incy > 0` and `inca > 0`.

For example, setting incy = 1 specifies gathering array elements into a contiguous vector.

This method is similar to that used in BLAS, with the exception that negative and zero increments are not permitted.

Index Vector Indexing

```
kj = iy(j), mj = ia(j), j = 1 ,..., n .
```

.

where ia and iy are arrays of length *n* that contain index vectors for the input and output arrays *a* and *y*, respectively.

Mask Vector Indexing

Indices `kj` , `mj` are such that:

```
my(kj) ≠ 0, ma(mj) ≠ 0 , j = 1,..., n .
```

.

where `ma` and `my` are arrays that contain mask vectors for the input and output arrays *a* and *y*, respectively.

Vector Mathematical Functions

Matrix Arguments

Matrix arguments of the Intel® oneAPI Math Kernel Library routines can be stored ineither one- or two-dimensional arrays, using the following storage schemes:

- conventional full storage(in a two-dimensional array)
- packed storage for Hermitian, symmetric, or triangular matrices (in a one-dimensional array)
- band storage for band matrices (in a two-dimensional array)
- rectangular full packed storage for symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels.

Full storage is the simplest scheme. A matrix *A* is stored in a two-dimensional array *a*, with the matrix element a_{ij} stored in the array element `a(i,j)` . , where *lda* is the leading dimension of array *a*.

If a matrix is triangular (upper or lower, as specified by the argument *uplo*), only the elements of the relevant triangle are stored; the remaining elements of the array need not be set.

Routines that handle symmetric or Hermitian matrices allow for either the upper or lower triangle of the matrix to be stored in the corresponding elements of the array:

if *uplo* ='U', a_{ij} is stored as described for $i \le j$, other elements of *a* need not be set.

if *uplo* ='L', a_{ij} is stored as described for $j \le i$, other elements of *a* need not be set.

Packed storage allows you to store symmetric, Hermitian, or triangular matrices more compactly: the relevant triangle (again, as specified by the argument *uplo*) is packed by columns in a one-dimensional array *ap*:

if *uplo* ='U', a_{ij} is stored in $ap(i + j(j - 1)/2)$ for $i \le j$

if *uplo* ='L', a_{ij} is stored in $ap(i + (2*n - j)*(j - 1)/2)$ for $j \le i$.

In descriptions of LAPACK routines, arrays with packed matrices have names ending in *p*.

Band storage is as follows: an *m*-by-*n* band matrix with *kl* non-zero sub-diagonals and *ku* non-zero super-diagonals is stored compactly in a two-dimensional array *ab* with *kl*+*ku* + 1 rows and *n* columns. Columns of the matrix are stored in the corresponding columns of the array, and diagonals of the matrix are stored in rows of the array . Thus,

a_{ij} is stored in *ab*(*ku*+1+*i*-*j*,*j*) for max(1,*j*-*ku*) ≤ *i* ≤ min(*n*,*j*+*kl*).

Use the band storage scheme only when *kl* and *ku* are much less than the matrix size *n*. Although the routines work correctly for all values of *kl* and *ku*, using the band storage is inefficient if your matrices are not really banded.

The band storage scheme is illustrated by the following example, when

$m = n = 6,\ kl = 2,\ ku = 1$

Array elements marked * are not used by the routines:

Banded matrix A

$$\begin{bmatrix} a_{11} & a_{12} & 0 & 0 & 0 & 0 \\ a_{21} & a_{22} & a_{23} & 0 & 0 & 0 \\ a_{31} & a_{32} & a_{33} & a_{34} & 0 & 0 \\ 0 & a_{42} & a_{43} & a_{44} & a_{45} & 0 \\ 0 & 0 & a_{53} & a_{54} & a_{55} & a_{56} \\ 0 & 0 & 0 & a_{64} & a_{65} & a_{66} \end{bmatrix}$$

Band storage of A

$$\begin{matrix} * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{matrix}$$

When a general band matrix is supplied for *LU factorization*, space must be allowed to store *kl* additional super-diagonals generated by fill-in as a result of row interchanges. This means that the matrix is stored according to the above scheme, but with $kl + ku$ super-diagonals. Thus,

a_{ij} is stored in $ab(kl+ku+1+i-j,j)$ for $\max(1,j-ku) \le i \le \min(n,j+kl)$.

The band storage scheme for LU factorization is illustrated by the following example, when$m = n = 6,\ kl = 2,\ ku = 1$:

Banded matrix A

$$\begin{bmatrix} a_{11} & a_{12} & 0 & 0 & 0 & 0 \\ a_{21} & a_{22} & a_{23} & 0 & 0 & 0 \\ a_{31} & a_{32} & a_{33} & a_{34} & 0 & 0 \\ 0 & a_{42} & a_{43} & a_{44} & a_{45} & 0 \\ 0 & 0 & a_{53} & a_{54} & a_{55} & a_{56} \\ 0 & 0 & 0 & a_{64} & a_{65} & a_{66} \end{bmatrix}$$

Band storage of A

*	*	*	+	+	+
*	*	+	+	+	+
*	a_{12}	a_{23}	a_{34}	a_{45}	a_{56}
a_{11}	a_{22}	a_{33}	a_{44}	a_{55}	a_{66}
a_{21}	a_{32}	a_{43}	a_{54}	a_{65}	*
a_{31}	a_{42}	a_{53}	a_{64}	*	*

Array elements marked * are not used by the routines; elements marked + need not be set on entry, but are required by the LU factorization routines to store the results. The input array will be overwritten on exit by the details of the LU factorization as follows:

*	*	*	u_{14}	u_{25}	u_{36}
*	*	u_{13}	u_{24}	u_{35}	u_{46}
*	u_{12}	u_{23}	u_{34}	u_{45}	u_{56}
u_{11}	u_{22}	u_{33}	u_{44}	u_{55}	u_{66}
m_{21}	m_{32}	m_{43}	m_{54}	m_{65}	*
m_{31}	m_{42}	m_{53}	m_{64}	*	*

where u_{ij} are the elements of the upper triangular matrix U, and m_{ij} are the multipliers used during factorization.

Triangular band matrices are stored in the same format, with either *kl*= 0 if upper triangular, or $ku = 0$ if lower triangular. For symmetric or Hermitian band matrices with *k* sub-diagonals or super-diagonals, you need to store only the upper or lower triangle, as specified by the argument *uplo*:

if *uplo* ='U', a_{ij} is stored in *ab*(*k*+1+*i*-*j*,*j*) for $\max(1,j-k) \le i \le j$

if *uplo* ='L', a_{ij} is stored in *ab*(1+*i*-*j*,*j*) for $j \le i \le \min(n,j+k)$.

In descriptions of LAPACK routines, arrays that hold matrices in band storage have names ending in *b*.

In Fortran, column-major ordering of storage is assumed. This means that elements of the same column occupy successive storage locations.

Three quantities are usually associated with a two-dimensional array argument: its leading dimension, which specifies the number of storage locations between elements in the same row, its number of rows, and its number of columns. For a matrix in full storage, the leading dimension of the array must be at least as large as the number of rows in the matrix.

A character transposition parameter is often passed to indicate whether the matrix argument is to be used in normal or transposed form or, for a complex matrix, if the conjugate transpose of the matrix is to be used.

The values of the transposition parameter for these three cases are the following:

'N' or *'n'*	normal (no conjugation, no transposition)
'T' or *'t'*	transpose
'C' or *'c'*	conjugate transpose.

Example. Two-Dimensional Complex Array

Suppose *A* (1:5, 1:4) is the complex two-dimensional array presented by matrix

$$\begin{bmatrix} (1.1,0.11) & (1.2,0.12) & (1.3,0.13) & (1.4,0.14) \\ (2.1,0.21) & (2.2,0.22) & (2.3,0.23) & (1.4,0.24) \\ (3.1,0.31) & (3.2,0.32) & (3.3,0.33) & (1.4,0.34) \\ (4.1,0.41) & (4.2,0.42) & (4.3,0.43) & (1.4,0.44) \\ (5.1,0.51) & (5.2,0.52) & (5.3,0.53) & (1.4,0.54) \end{bmatrix}$$

Let *transa* be the transposition parameter, *m* be the number of rows, *n* be the number of columns, and *lda* be the leading dimension. Then if

transa = *'N'*, *m* = 4, *n* = 2, and *lda* = 5, the matrix argument would be

$$\begin{bmatrix} (1.1,0.11) & (1.2,0.12) \\ (2.1,0.21) & (2.2,0.22) \\ (3.1,0.31) & (3.2,0.32) \\ (4.1,0.41) & (4.2,0.42) \end{bmatrix}$$

If *transa* = *'T'*, *m* = 4, *n* = 2, and *lda* =5, the matrix argument would be

$$\begin{bmatrix} (1.1,0.11) & (2.1,0.21) & (3.1,0.31) & (4.1,0.41) \\ (1.2,0.12) & (2.2,0.22) & (3.2,0.32) & (4.2,0.42) \end{bmatrix}$$

If *transa* = 'C', *m* = 4, *n* = 2, and *lda* =5, the matrix argument would be

$$\begin{bmatrix} (1.1,-0.11) & (2.1,-0.21) & (3.1,-0.31) & (4.1,-0.41) \\ (1.2,-0.12) & (2.2,-0.22) & (3.2,-0.32) & (4.2,-0.42) \end{bmatrix}$$

Note that care should be taken when using a leading dimension value which is different from the number of rows specified in the declaration of the two-dimensional array. For example, suppose the array *A* above is declared as `COMPLEX A (5,4)`.

Then if *transa* = 'N', *m* = 3, *n* = 4, and *lda* = 4, the matrix argument will be

$$\begin{bmatrix} (1.1,0.11) & (5.1,0.51) & (4.2,0.42) & (3.3,0.33) \\ (2.1,0.21) & (1.2,0.12) & (5.2,0.52) & (4.3,0.43) \\ (3.1,0.31) & (2.2,0.22) & (1.3,0.13) & (5.3,0.53) \end{bmatrix}$$

Rectangular Full Packed storage allows you to store symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels. To store an *n*-by-*n* triangle (and suppose for simplicity that *n* is even), you partition the triangle into three parts: two *n*/2-by-*n*/2 triangles and an *n*/2-by-*n*/2 square, then pack this as an *n*-by-*n*/2 rectangle (or *n*/2-by-*n* rectangle), by transposing (or transpose-conjugating) one of the triangles and packing it next to the other triangle. Since the two triangles are stored in full storage, you can use existing efficient routines on them.

There are eight cases of RFP storage representation: when *n* is even or odd, the packed matrix is transposed or not, the triangular matrix is lower or upper. See below for all the eight storage schemes illustrated:

n is odd, *A* is lower triangular

Full format

$$\begin{matrix} a_{11} & X & X & X & X & X & X \\ a_{21} & a_{22} & X & X & X & X & X \\ a_{31} & a_{32} & a_{33} & X & X & X & X \\ a_{41} & a_{42} & a_{43} & a_{44} & X & X & X \\ \mathbf{a_{51}} & \mathbf{a_{52}} & \mathbf{a_{53}} & \mathbf{a_{54}} & a_{55} & X & X \\ \mathbf{a_{61}} & \mathbf{a_{62}} & \mathbf{a_{63}} & \mathbf{a_{64}} & a_{65} & a_{66} & X \\ \mathbf{a_{71}} & \mathbf{a_{72}} & \mathbf{a_{73}} & \mathbf{a_{74}} & a_{75} & a_{76} & a_{77} \end{matrix}$$

RFP (not transposed)

$$\begin{matrix} a_{11} & a_{55} & a_{65} & a_{75} \\ a_{21} & a_{22} & a_{66} & a_{76} \\ a_{31} & a_{32} & a_{33} & a_{77} \\ a_{41} & a_{42} & a_{43} & a_{44} \\ \mathbf{a_{51}} & \mathbf{a_{52}} & \mathbf{a_{53}} & \mathbf{a_{54}} \\ \mathbf{a_{61}} & \mathbf{a_{62}} & \mathbf{a_{63}} & \mathbf{a_{64}} \\ \mathbf{a_{71}} & \mathbf{a_{72}} & \mathbf{a_{73}} & \mathbf{a_{74}} \end{matrix}$$

RFP (transposed)

$$\begin{matrix} a_{11} & a_{21} & a_{31} & a_{41} & \mathbf{a_{51}} & \mathbf{a_{61}} & \mathbf{a_{71}} \\ a_{55} & a_{22} & a_{32} & a_{42} & \mathbf{a_{52}} & \mathbf{a_{62}} & \mathbf{a_{72}} \\ a_{65} & a_{66} & a_{33} & a_{43} & \mathbf{a_{53}} & \mathbf{a_{63}} & \mathbf{a_{73}} \\ a_{75} & a_{76} & a_{77} & a_{44} & \mathbf{a_{54}} & \mathbf{a_{64}} & \mathbf{a_{74}} \end{matrix}$$

n is even, *A* is lower triangular

Full format

$$\begin{matrix} a_{11} & X & X & X & X & X \\ a_{21} & a_{22} & X & X & X & X \\ a_{31} & a_{32} & a_{33} & X & X & X \\ \mathbf{a_{41}} & \mathbf{a_{42}} & \mathbf{a_{43}} & a_{44} & X & X \\ \mathbf{a_{51}} & \mathbf{a_{52}} & \mathbf{a_{53}} & a_{54} & a_{55} & X \\ \mathbf{a_{61}} & \mathbf{a_{62}} & \mathbf{a_{63}} & a_{64} & a_{65} & a_{66} \end{matrix}$$

RFP (not transposed)

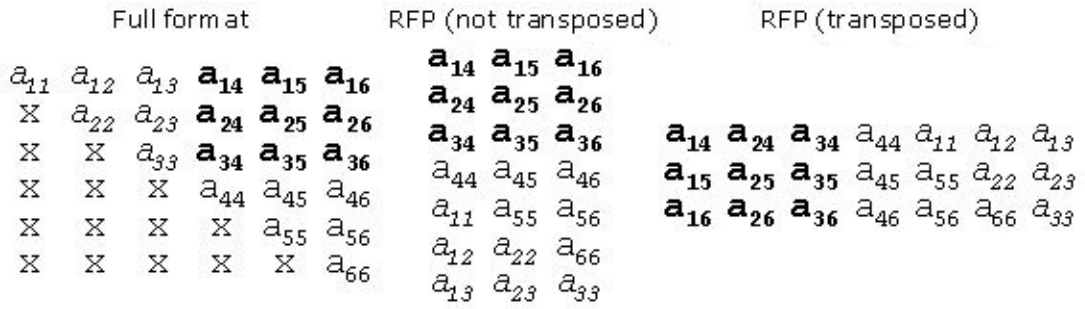
$$\begin{matrix} a_{44} & a_{54} & a_{64} \\ a_{11} & a_{55} & a_{65} \\ a_{21} & a_{22} & a_{66} \\ a_{31} & a_{32} & a_{33} \\ \mathbf{a_{41}} & \mathbf{a_{42}} & \mathbf{a_{43}} \\ \mathbf{a_{51}} & \mathbf{a_{52}} & \mathbf{a_{53}} \\ \mathbf{a_{61}} & \mathbf{a_{62}} & \mathbf{a_{63}} \end{matrix}$$

RFP (transposed)

$$\begin{matrix} a_{44} & a_{11} & a_{21} & a_{31} & \mathbf{a_{41}} & \mathbf{a_{51}} & \mathbf{a_{61}} \\ a_{54} & a_{55} & a_{22} & a_{32} & \mathbf{a_{42}} & \mathbf{a_{52}} & \mathbf{a_{62}} \\ a_{64} & a_{65} & a_{66} & a_{33} & \mathbf{a_{43}} & \mathbf{a_{53}} & \mathbf{a_{63}} \end{matrix}$$

n is odd, *A* is upper triangular

n is even, *A* is upper triangular



Intel® oneAPI Math Kernel Library (oneMKL) provides a number of routines such as`?hfrk`, `?sfrk` performing BLAS operations working directly on RFP matrices, as well as some conversion routines, for instance, `?tpttf` goes from the standard packed format to RFP and `?trttf` goes from the full format to RFP.

Please refer to the Netlib site for more information.

Note that in the descriptions of LAPACK routines, arrays with RFP matrices have names ending in `fp`.

Appendix C: Specific Features of Fortran 95 Interfaces for LAPACK Routines

Intel® MKL implements Fortran 95 interface for LAPACK package, further referred to as MKL LAPACK95, to provide full capacity of MKL FORTRAN 77 LAPACK routines. This is the principal difference of Intel MKL from the Netlib Fortran 95 implementation for LAPACK.

A new feature of MKL LAPACK95 by comparison with Intel MKL LAPACK77 implementation is presenting a package of source interfaces along with wrappers that make the implementation compiler-independent. As a result, the MKL LAPACK package can be used in all programming environments intended for Fortran 95.

Depending on the degree and type of difference from Netlib implementation, the MKL LAPACK95 interfaces fall into several groups that require different transformations (see "MKL Fortran 95 Interfaces for LAPACK Routines vs. Netlib Implementation"). The groups are given in full with the calling sequences of the routines and appropriate differences from Netlib analogs.

The following conventions are used:

```
<interface> ::=  <name of interface> '(' <arguments list>')'
<arguments list> ::=  <first argument> {<argument>}*
<first argument> ::=  < identifier >
<argument> ::=  <required argument>|<optional argument>
<required argument> ::=  ',' <identifier>
<optional argument> ::=  '[,' <identifier> ']'
<name of interface> ::=  <identifier>
```

where defined notions are separated from definitions by `::=`, notion names are marked by angle brackets, terminals are given in quotes, and `{…}*` denotes repetition zero, one, or more times.

<first argument> and each *<required argument>* should be present in all calls of denoted interface, *<optional argument>* may be omitted. Comments to interface definitions are provided where necessary. Comment lines begin with character `!`.

Two interfaces with one name are presented when two variants of subroutine calls (separated by types of arguments) exist.

Appendix D: FFTW Interface to Intel® Math Kernel Library

Intel® oneAPI Math Kernel Library (oneMKL) offers FFTW2 and FFTW3 interfaces to Intel® oneAPI Math Kernel Library (oneMKL) Fast Fourier Transform and Trigonometric Transform functionality. The purpose of these interfaces is to enable applications using FFTW (www.fftw.org) to gain performance with Intel® oneAPI Math Kernel Library (oneMKL) without changing the program source code.

Both FFTW2 and FFTW3 interfaces are provided in open source as FFTW wrappers to Intel® oneAPI Math Kernel Library (oneMKL). For ease of use, FFTW3 interface is also integrated in Intel® oneAPI Math Kernel Library (oneMKL).

FFTW Notational Conventions

This appendix typically employs path notations for Windows* OS.

FFTW2 Interface to Intel® oneAPI Math Kernel Library

This section describes a collection of C and Fortran wrappers providing FFTW 2.x interface to Intel® oneAPI Math Kernel Library (oneMKL). The wrappers translate calls to FFTW 2.x functions into the calls of the Intel® oneAPI Math Kernel Library (oneMKL) Fast Fourier Transform interface (FFT interface).

Note that Intel® oneAPI Math Kernel Library (oneMKL) FFT interface operates on both single- and double-precision floating-point data types.

Because of differences between FFTW and Intel® oneAPI Math Kernel Library (oneMKL) FFT functionalities, there are restrictions on using wrappers instead of the FFTW functions. Some FFTW functions have empty wrappers. However, many typical FFTs can be computed using these wrappers.

Refer to Fourier Transform Functions, for better understanding the effects from the use of the wrappers.

Wrappers Reference

The section provides a brief reference for the FFTW 2.x C interface. For details please refer to the original FFTW 2.x documentation available at www.fftw.org.

Each FFTW function has its own wrapper. Some of them, which are *not* expressly listed in this section, are empty and do nothing, but they are provided to avoid link errors and satisfy the function calls.

Limitations of the FFTW2 Interface to Intel® oneAPI Math Kernel Library (oneMKL)

One-dimensional Complex-to-complex FFTs

The following functions compute a one-dimensional complex-to-complex Fast Fourier transform.

```
fftw_plan fftw_create_plan(int n, fftw_direction dir, int flags);
```

```
fftw_plan fftw_create_plan_specific(int n, fftw_direction dir, int flags, fftw_complex
*in, int istride, fftw_complex *out, int ostride);
```

```
void fftw(fftw_plan plan, int howmany, fftw_complex *in, int istride, int idist,
fftw_complex *out, int ostride, int odist);
```

```
void fftw_one(fftw_plan plan, fftw_complex *in , fftw_complex *out);

void fftw_destroy_plan(fftw_plan plan);
```

Multi-dimensional Complex-to-complex FFTs

The following functions compute a multi-dimensional complex-to-complex Fast Fourier transform.

```
fftwnd_plan fftwnd_create_plan(int rank, const int *n, fftw_direction dir, int flags);

fftwnd_plan fftw2d_create_plan(int nx, int ny, fftw_direction dir, int flags);

fftwnd_plan fftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir, int flags);

fftwnd_plan fftwnd_create_plan_specific(int rank, const int *n, fftw_direction dir, int
flags, fftw_complex *in, int istride, fftw_complex *out, int ostride);

fftwnd_plan fftw2d_create_plan_specific(int nx, int ny, fftw_direction dir, int flags,
fftw_complex *in, int istride, fftw_complex *out, int ostride);

fftwnd_plan fftw3d_create_plan_specific(int nx, int ny, int nz, fftw_direction dir, int
flags, fftw_complex *in, int istride, fftw_complex *out, int ostride);

void fftwnd(fftwnd_plan plan, int howmany, fftw_complex *in, int istride, int idist,
fftw_complex *out, int ostride, int odist);

void fftwnd_one(fftwnd_plan plan, fftw_complex *in, fftw_complex *out);

void fftwnd_destroy_plan(fftwnd_plan plan);
```

One-dimensional Real-to-half-complex/Half-complex-to-real FFTs

Half-complex representation of a conjugate-even symmetric vector of size *N* in a real array of the same size *N* consists of *N*/2+1 real parts of the elements of the vector followed by non-zero imaginary parts in the reverse order. Because the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface does not currently support this representation, all wrappers of this kind are empty and do nothing.

Nevertheless, you can perform one-dimensional real-to-complex and complex-to-real transforms using `rfftwnd` functions with *rank*=1.

int flags, fftw_real *in, int istride, fftw_real *out, int ostride);
```

```
void rfftwnd_real_to_complex(rfftwnd_plan plan, int howmany, fftw_real *in, int
istride, int idist, fftw_complex *out, int ostride, int odist);
void rfftwnd_complex_to_real(rfftwnd_plan plan, int howmany, fftw_complex *in, int
istride, int idist, fftw_real *out, int ostride, int odist);
void rfftwnd_one_real_to_complex(rfftwnd_plan plan, fftw_real *in, fftw_complex *out);
void rfftwnd_one_complex_to_real(rfftwnd_plan plan, fftw_complex *in, fftw_real *out);
void rfftwnd_destroy_plan(rfftwnd_plan plan);
```

Multi-threaded FFTW

Unlike the original FFTW interface, every computational function in the FFTW2 interface to Intel® oneAPI Math Kernel Library (oneMKL) provides multithreaded computation by default, with the maximum number of threads permitted in FFT functions (see "Techniques to Set the Number of Threads" in *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*). To limit the number of threads, call the threaded FFTW computational functions:

```
void fftw_threads(int nthreads, fftw_plan plan, int howmany, fftw_complex *in, int
istride, int idist, fftw_complex *out, int ostride, int odist);
void fftw_threads_one(int nthreads, rfftwnd_plan plan, fftw_complex *in, fftw_complex
*out);
...
void rfftwnd_threads_real_to_complex( int nthreads, rfftwnd_plan plan, int howmany,
fftw_real *in, int istride, int idist, fftw_complex *out, int ostride, int odist);
```

Compared to its non-threaded counterpart, every threaded computational function has `threads_` as the second part of its name and additional first parameter *nthreads*. Set the *nthreads* parameter to the thread limit to ensure that the computation requires at most that number of threads.

FFTW Support Functions

The FFTW wrappers provide memory allocation functions to be used with FFTW:

```
void* fftw_malloc(size_t n);
void fftw_free(void* x);
```

The `fftw_malloc` wrapper aligns the memory on a 16-byte boundary.

If `fftw_malloc` fails to allocate memory, it aborts the application. To override this behavior, set a global variable `fftw_malloc_hook` and optionally the complementary variable `fftw_free_hook`:

```
void *(*fftw_malloc_hook) (size_t n);
void (*fftw_free_hook) (void *p);
```

The wrappers use the function `fftw_die` to abort the application in cases when a caller cannot be informed of an error otherwise (for example, in computational functions that return `void`). To override this behavior, set a global variable `fftw_die_hook`:

```
void (*fftw_die_hook)(const char *error_string);
void fftw_die(const char *s);
```

Calling FFTW2 Interface Wrappers from Fortran

The FFTW2 wrappers to Intel® oneAPI Math Kernel Library (oneMKL) provide the following subroutines for calling from Fortran:

```
call fftw_f77_create_plan(plan, n, dir, flags)
call fftw_f77(plan, howmany, in, istride, idist, out, ostride, odist)
call fftw_f77_one(plan, in, out)
call fftw_f77_threads(nthreads, plan, howmany, in, istride, idist, out, ostride, odist)
call fftw_f77_threads_one(nthreads, plan, in, out)
call fftw_f77_destroy_plan(plan)

call fftwnd_f77_create_plan(plan, rank, n, dir, flags)
call fftw2d_f77_create_plan(plan, nx, ny, dir, flags)
call fftw3d_f77_create_plan(plan, nx, ny, nz, dir, flags)
call fftwnd_f77(plan, howmany, in, istride, idist, out, ostride, odist)
call fftwnd_f77_one(plan, in, out)
call fftwnd_f77_threads(nthreads, plan, howmany, in, istride, idist, out, ostride,
odist)
call fftwnd_f77_threads_one(nthreads, plan, in, out)
call fftwnd_f77_destroy_plan(plan)

call rfftw_f77_create_plan(plan, n, dir, flags)
call rfftw_f77(plan, howmany, in, istride, idist, out, ostride, odist)
call rfftw_f77_one(plan, in, out)
call rfftw_f77_threads(nthreads, plan, howmany, in, istride, idist, out, ostride, odist)
call rfftw_f77_threads_one(nthreads, plan, in, out)
call rfftw_f77_destroy_plan(plan)

call rfftwnd_f77_create_plan(plan, rank, n, dir, flags)
call rfftw2d_f77_create_plan(plan, nx, ny, dir, flags)
call rfftw3d_f77_create_plan(plan, nx, ny, nz, dir, flags)
call rfftwnd_f77_complex_to_real(plan, howmany, in, istride, idist, out, ostride, odist)
call rfftwnd_f77_one_complex_to_real (plan, in, out)
call rfftwnd_f77_real_to_complex(plan, howmany, in, istride, idist, out, ostride, odist)
call rfftwnd_f77_one_real_to_complex (plan, in, out)
call rfftwnd_f77_threads_complex_to_real(nthreads, plan, howmany, in, istride, idist,
out, ostride, odist)
call rfftwnd_f77_threads_one_complex_to_real(nthreads, plan, in, out)
call rfftwnd_f77_threads_real_to_complex(nthreads, plan, howmany, in, istride, idist,
out, ostride, odist)
call rfftwnd_f77_threads_one_real_to_complex(nthreads, plan, in, out)
call rfftwnd_f77_destroy_plan(plan)

call fftw_f77_threads_init(info)
```

The FFTW Fortran functions are wrappers to FFTW C functions.

See also these resources:

www.fftw.org	for the original FFTW 2.x documentation.
Limitations of the FFTW2 Interface to Intel MKL	for limitations of the wrappers.

Limitations of the FFTW2 Interface to Intel® oneAPI Math Kernel Library (oneMKL)

The FFTW2 wrappers implement the functionality of only those FFTW functions that Intel® oneAPI Math Kernel Library (oneMKL) can reasonably support. Other functions are provided as no-operation functions, whose only purpose is to satisfy link-time symbol resolution. Specifically, no-operation functions include:

- Real-to-half-complex and respective backward transforms
- Print plan functions
- Functions for importing/exporting/forgetting wisdom
- Most of the FFTW functions not covered by the original FFTW2 documentation

Because the Intel® oneAPI Math Kernel Library (oneMKL) implementation of FFTW2 wrappers does not use plan and plan node structures declared in `fftw.h`, the behavior of an application that relies on the internals of the plan structures defined in that header file is undefined.

FFTW2 wrappers define plan as a set of attributes, such as strides, used to commit the Intel® oneAPI Math Kernel Library (oneMKL) FFT descriptor structure. If an FFTW2 computational function is called with attributes different from those recorded in the plan, the function attempts to adjust the attributes of the plan and recommit the descriptor. So, repeated calls of a computational function with the same plan but different strides, distances, and other parameters may be performance inefficient.

Plan creation functions disregard most planner flags passed through the *flags* parameter. These functions take into account only the following values of *flags*:

- `FFTW_IN_PLACE`

  If this value of *flags* is supplied, the plan is marked so that computational functions using that plan ignore the parameters related to output (*out*, *ostride*, and *odist*). Unlike the original FFTW interface, the wrappers never use the *out* parameter as a scratch space for in-place transforms.
- `FFTW_THREADSAFE`

  If this value of *flags* is supplied, the plan is marked read-only. An attempt to change attributes of a read-only plan aborts the application.

FFTW wrappers are generally not thread safe. Therefore, do not use the same plan in parallel user threads simultaneously.

Installing FFTW2 Interface Wrappers

Wrappers are delivered as source code, which you must compile to build the wrapper library. Then you can substitute the wrapper and Intel® oneAPI Math Kernel Library (oneMKL) libraries for the FFTW library. The source code for the wrappers, makefiles, and files with lists of wrappers are located in the `.\interfaces\fftw2xf`subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

Creating the Wrapper Library

Three header files are used to compile the Fortran wrapper library: `fftw2_mkl.h`, `fftw2_f77_mkl.h`, and `fftw.h`. The `fftw2_mkl.h` and `fftw2_f77_mkl.h` files are located in the `.\interfaces\fftw2xf\wrappers`subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

The file `fftw.h`, used to compile libraries and located in the `.\include\fftw`subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory, slightly differs from the original FFTW (www.fftw.org) header file`fftw.h`.

The source code for the wrappers, makefiles, and files with lists of functions are located in the `.\interfaces\fftw2xf` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

A wrapper library contains wrappers for complex and real transforms in a serial and multi-threaded mode for double- or single-precision floating-point data types. A makefile parameter manages the data type.

Parameters of a makefile also specify the platform (required), compiler, and data precision. The makefile comment heading provides the exact description of these parameters.

Because a C compiler builds the Fortran wrapper library, function names in the wrapper library and Fortran object module may be different. The file `fftw2_f77_mkl.h` in the `.\interfaces\fftw2xf \source`subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory defines function names according to the names in the Fortran module. If a required name is missing in the file, you can modify the file to add the name before building the library.

To build the library, run the `make` command on Linux* OS and macOS* or the `nmake` command on Windows* OS with appropriate parameters.

For example, on Linux OS the command

```
make libintel64
```

builds a double-precision wrapper library for Intel® 64 architecture based applications using the Intel® oneAPI DPC++/C++ Compiler or the Intel® Fortran Compiler (Compilers and data precision are chosen by default.)

Each makefile creates the library in the directory with Intel® oneAPI Math Kernel Library (oneMKL) libraries corresponding to the platform used. For example, `./lib/ia32` (on Linux OS and macOS) or `.\lib\ia32` (on Windows* OS).

In the names of a wrapper library, the suffix corresponds to the compiler used and the letter preceding the underscore is `"f"` for the Fortran programming language.

For example,

`fftw2xf_intel.lib` (on Windows OS); `libfftw2xf_intel.a` (on Linux OS and macOS);

Application Assembling

Use the necessary original FFTW (www.fftw.org) header files without any modifications. Use the created wrapper library and the Intel® oneAPI Math Kernel Library (oneMKL) library instead of the FFTW library.

Running FFTW2 Interface Wrapper Examples

Intel® oneAPI Math Kernel Library (oneMKL) provides examples to demonstrate how to use the MPI FFTW wrapper library. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw2xf` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory . To build examples, several additional files are needed: `fftw.h`, `fftw_threads.h`, `rfftw.h`, `rfftw_threads.h`, and `fftw_f77.i`. These files are distributed with permission from FFTW and are available in `.\include\fftw`. The original files can also be found in FFTW 2.1.5 at http://www.fftw.org/download.html.

An example makefile uses the `function` parameter in addition to the parameters of the corresponding wrapper library makefile (see Creating a Wrapper Library). The makefile comment heading provides the exact description of these parameters.

An example makefile normally invokes examples. However, if the appropriate wrapper library is not yet created, the makefile first builds the library the same way as the wrapper library makefile does and then proceeds to examples.

If the parameter `function=<example_name>` is defined, only the specified example runs. Otherwise, all examples from the appropriate subdirectory run. The subdirectory `.\_results` is created, and the results are stored there in the `<example_name>.res` files.

FFTW3 Interface to Intel® oneAPI Math Kernel Library

This section describes a collection of FFTW3 wrappers to Intel® oneAPI Math Kernel Library (oneMKL). The wrappers translate calls of FFTW3 functions to the calls of the Intel® oneAPI Math Kernel Library (oneMKL) Fourier transform (FFT) or Trigonometric Transform (TT) functions. The purpose of FFTW3 wrappers is to enable developers whose programs currently use the FFTW3 library to gain performance with the Intel® oneAPI Math Kernel Library (oneMKL) Fourier transforms without changing the program source code.

The FFTW3 wrappers provide a limited functionality compared to the original FFTW 3.x library, because of differences between FFTW and Intel® oneAPI Math Kernel Library (oneMKL) FFT and TT functionality. This section describes limitations of the FFTW3 wrappers and hints for their usage. Nevertheless, many typical FFT tasks can be performed using the FFTW3 wrappers to Intel® oneAPI Math Kernel Library (oneMKL).

The FFTW3 wrappers are integrated in Intel® oneAPI Math Kernel Library (oneMKL). The only change required to use Intel® oneAPI Math Kernel Library (oneMKL) through the FFTW3 wrappers is to link your application using FFTW3 against Intel® oneAPI Math Kernel Library (oneMKL).

A reference implementation of the FFTW3 wrappers is also provided in open source. You can find it in the `interfaces` directory of the Intel® oneAPI Math Kernel Library (oneMKL) distribution. You can use the reference implementation to create your own wrapper library (see Building Your Own Wrapper Library)

See also these resources:

Intel® oneAPI Math Kernel Library (oneMKL) Release Notes	for the version of the FFTW3 library supported by the wrappers.
www.fftw.org	for a description of the FFTW interface.
Fourier Transform Functions	for a description of the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface.
Trigonometric Transform Routines	for a description of Intel® oneAPI Math Kernel Library (oneMKL) TT interface.

Using FFTW3 Wrappers

The FFTW3 wrappers are a set of functions and data structures depending on one another. The wrappers are not designed to provide the interface on a function-per-function basis. Some FFTW3 wrapper functions are empty and do nothing, but they are present to avoid link errors and satisfy function calls.

This document does not list the declarations of the functions that the FFTW3 wrappers provide (you can find the declarations in the `fftw3.h` header file). Instead, this section comments on particular limitations of the wrappers and provides usage hints:. These are some known limitations of FFTW3 wrappers and their usage in Intel® oneAPI Math Kernel Library (oneMKL).

- The FFTW3 wrappers do not support long double precision because Intel® oneAPI Math Kernel Library (oneMKL) FFT functions operate only on single- and double-precision floating-point data types. Therefore the functions with prefix `fftwl_`, supporting the `long double` data type, are not provided.
- The wrappers provide equivalent implementation for double- and single-precision functions (those with prefixes `fftw_` and `fftwf_`, respectively). So, all these comments equally apply to the double- and single-precision functions and will refer to functions with prefix `fftw_`, that is, double-precision functions, for brevity.
- The FFTW3 interface that the wrappers provide is defined in the `fftw3.h` and `fftw3.f` header files. These files are borrowed from the FFTW3.x package and distributed within Intel® oneAPI Math Kernel Library (oneMKL) with permission. Additionally, the `fftw3_mkl.h`, `fftw3_mkl.f`, and `fftw3_mkl_f77.h` header files define supporting structures and supplementary constants and macros as well as expose Fortran interface in C.

- Actual functionality of the plan creation wrappers is implemented in guru64 set of functions. Basic interface, advanced interface, and guru interface plan creation functions call the guru64 interface functions. So, all types of the FFTW3 plan creation interface in the wrappers are functional.
- Plan creation functions may return a `NULL` plan, indicating that the functionality is not supported. So, please carefully check the result returned by plan creation functions in your application. In particular, the following problems return a `NULL` plan:
  - c2r and r2c problems with a split storage of complex data.
  - r2r problems with *kind* values `FFTW_R2HC`, `FFTW_HC2R`, and `FFTW_DHT`. The only supported r2r kinds are even/odd DFTs (sine/cosine transforms).
  - Multidimensional r2r transforms.
  - Transforms of multidimensional vectors. That is, the only supported values for parameter *howmany_rank* in guru and guru64 plan creation functions are 0 and 1.
  - Multidimensional transforms with *rank* > MKL_MAXRANK.
- The `MKL_RODFT00` value of the *kind* parameter is introduced by the FFTW3 wrappers. For better performance, you are strongly encouraged to use this value rather than `FFTW_RODFT00`. To use this *kind* value, provide an extra first element equal to 0.0 for the input/output vectors. Consider the following example:

```
plan1 = fftw_plan_r2r_1d(n, in1, out1, FFTW_RODFT00, FFTW_ESTIMATE);
plan2 = fftw_plan_r2r_1d(n, in2, out2, MKL_RODFT00, FFTW_ESTIMATE);
```

  Both plans perform the same transform, except that the *in2/out2* arrays have one extra zero element at location 0. For example, if *n*=3, *in1*={*x,y,z*} and *out1*={*u,v,w*}, then *in2*={0,*x,y,z*} and *out2*={0,*u,v,w*}.
- The *flags* parameter in plan creation functions is always ignored. The same algorithm is used regardless of the value of this parameter. In particular, *flags* values `FFTW_ESTIMATE`, `FFTW_MEASURE`, etc. have no effect.
- For multithreaded plans, use normal sequence of calls to the `fftw_init_threads()` and `fftw_plan_with_nthreads()` functions (refer to FFTW documentation).
- Memory allocation function `fftw_malloc` returns memory aligned at a 16-byte boundary. You must free the memory with `fftw_free`.
- Fortran wrappers (see Calling Wrappers from Fortran) use the `INTEGER` type, which is 32-bit in LP64 interfaces and 64-bit in ILP64 interfaces.
- The wrappers typically indicate a problem by returning a `NULL` plan. In a few cases, the wrappers may report a descriptive message of the problem detected. By default the reporting is turned off. To turn it on, set variable `fftw3_mkl.verbose` to a non-zero value, for example:

```
#include "fftw3.h"
#include "fftw3_mkl.h"
fftw3_mkl.verbose = 0;
plan = fftw_plan_r2r(...);
```

- The following functions are empty:
  - For saving, loading, and printing plans
  - For saving and loading wisdom
  - For estimating arithmetic cost of the transforms.
- Do not use macro `FFTW_DLL` with the FFTW3 wrappers to Intel® oneAPI Math Kernel Library (oneMKL).
- Do not use negative stride values. Though FFTW3 wrappers support negative strides in the part of advanced and guru FFTW interface, the underlying implementation does not.
- Do not set a FFTW2 wrapper library before a FFTW3 wrapper library or Intel® oneAPI Math Kernel Library (oneMKL) in your link line application. All libraries define "fftw_destroy_plan" symbol and linkage in incorrect order results into expected errors.

Calling FFTW3 Interface Wrappers from Fortran

Intel® oneAPI Math Kernel Library (oneMKL) also provides Fortran 77 interfaces of the FFTW3 wrappers. The Fortran wrappers are available for all FFTW3 interface functions and are based on C interface of the FFTW3 wrappers. Therefore they have the same functionality and restrictions as the corresponding C interface wrappers.

The Fortran wrappers use the default `INTEGER` type for integer arguments. The default `INTEGER`is 32-bit in Intel® oneAPI Math Kernel Library (oneMKL) LP64 interfaces and 64-bit in ILP64 interfaces. Argument*`plan`* in a Fortran application must have type `INTEGER*8`.

The wrappers that are double-precision subroutines have prefix `dfftw_`, single-precision subroutines have prefix `sfftw_` and provide an equivalent functionality. Long double subroutines (with prefix `lfftw_`) are not provided.

The Fortran FFTW3 wrappers use the default Intel® Fortran compiler convention for name decoration. If your compiler uses a different convention, or if you are using compiler options affecting the name decoration (such as `/Qlowercase`), you may need to compile the wrappers from sources, as described in section Building Your Own Wrapper Library.

For interoperability with C, the declaration of the Fortran FFTW3 interface is provided in header file `include/fftw/fftw3_mkl_f77.h`.

You can call Fortran wrappers from a FORTRAN 77 or Fortran 90 application, although Intel® oneAPI Math Kernel Library (oneMKL) does not provide a Fortran 90 module for the wrappers. For a detailed description of the FFTW Fortran interface, refer to FFTW3 documentation (www.fftw.org).

The following example illustrates calling the FFTW3 wrappers from Fortran:

```
INTEGER*8 plan
INTEGER N
INCLUDE 'fftw3.f'
COMPLEX*16 IN(*), OUT(*)
!...initialize array IN
CALL DFFTW_PLAN_DFT_1D(PLAN, N, IN, OUT, -1, FFTW_ESTIMATE)
IF (PLAN .EQ. 0) STOP
CALL DFFTW_EXECUTE
!...result is in array OUT
```

Building Your Own FFTW3 Interface Wrapper Library

The FFTW3 wrappers to Intel® oneAPI Math Kernel Library (oneMKL) are delivered both integrated in Intel® oneAPI Math Kernel Library (oneMKL) and as source code, which can be compiled to build a standalone wrapper library with exactly the same functionality. Normally you do not need to build the wrappers yourself.However, if your Fortran application is compiled with a compiler that uses a different name decoration than the Intel® Fortran compiler or if you are using compiler options altering the Fortran name decoration, you may need to build the wrappers that use the appropriate name changing convention.

The source code for the wrappers, makefiles, and files with lists of functions are located in the `.\interfaces\fftw3xf` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the `make` command on Linux* OS and macOS* or the `nmake` command on Windows* OS with a required target and optionally several parameters.

The target `libia32` or `libintel64` defines the platform architecture, and the other parameters specify the compiler, size of the default integer type, and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the `make` command is used to build the FFTW3 Fortran wrappers to Intel® oneAPI Math Kernel Library (oneMKL) for use from the GNU g77* Fortran compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3xf
make libintel64 compiler=gnu fname=a_name__ INSTALL_DIR=/my/path
```

This command builds the wrapper library using the GNU gcc compiler, decorates the name with the second underscore, and places the result, named `libfftw3xf_gnu.a`, into the `/my/path` directory. The name of the resulting library is composed of the name of the compiler used and may be changed by an optional parameter `INSTALL_LIBNAME`.

Building an Application With FFTW3 Interface Wrappers

Normally, the only change needed to build your application with FFTW3 wrappers replacing original FFTW library is to add Intel® oneAPI Math Kernel Library (oneMKL) at the link stage (see section *"Linking Your Application with Intel® oneAPI Math Kernel Library" in the Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*).

If you recompile your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

Sometimes, you may have to modify your application according to the following recommendations:

- The application requires

  `#include "fftw3.h"`,

  which it probably already includes.
- The application does not require

  `#include "mkl_dfti.h"` .
- The application does not require

  `#include "fftw3_mkl.h"` .

  It is required only in case you want to use the `MKL_RODFT00` constant.
- If the application does not check whether a `NULL` plan is returned by plan creation functions, this check must be added, because the FFTW3 to Intel® oneAPI Math Kernel Library (oneMKL) wrappers do not provide 100% of FFTW3 functionality.

Running FFTW3 Interface Wrapper Examples

There are some examples that demonstrate how to use the wrapper library. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw3xf` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory. To build Fortran examples, one additional file `fftw3.f` is needed. This file is distributed with permission from FFTW and is available in the `.\include\fftw`subdirectory of the Intel® oneAPI Math Kernel Library (oneMKL) directory. The original file can also be found in FFTW 3.3.4 at http://www.fftw.org/download.html.

Parameters of the example makefiles are similar to the parameters of the wrapper library makefiles. Example makefiles normally build and invoke the examples. If the parameter `function=<example_name>` is defined, then only the specified example will run. Otherwise, all examples will be executed. Results of running the examples are saved in subdirectory `.\_results` in files with extension `.res`.

For detailed information about options for the example makefile, refer to the makefile.

MPI FFTW3 Wrappers

This section describes a collection of MPI FFTW wrappers to Intel® oneAPI Math Kernel Library (oneMKL).

MPI FFTW wrappers are available only with Intel® oneAPI Math Kernel Library (oneMKL) for the Linux* and Windows* operating systems.

These wrappers translate calls of MPI FFTW functions to the calls of the Intel® oneAPI Math Kernel Library (oneMKL) cluster Fourier transform (CFFT) functions. The purpose of the wrappers is to enable users of MPI FFTW functions improve performance of the applications without changing the program source code.

Although the MPI FFTW wrappers provide less functionality than the original FFTW3 because of differences between MPI FFTW and Intel® oneAPI Math Kernel Library (oneMKL) CFFT, the wrappers cover many typical CFFT use cases.

The MPI FFTW wrappers are provided as source code. To use the wrappers, you need to build your own wrapper library (see Building Your Own Wrapper Library).

See also these resources:

Intel® oneAPI Math Kernel Library (oneMKL) Release Notes	for the version of the FFTW3 library supported by the wrappers.
www.fftw.org	for a description of the MPI FFTW interface.
Cluster FFT Functions	for a description of the Intel® oneAPI Math Kernel Library (oneMKL) CFFT interface.

Building Your Own Wrapper Library

The MPI FFTW wrappers for FFTW3 are delivered as source code, which can be compiled to build a wrapper library.

The source code for the wrappers, makefiles, and files with lists of functions are located in subdirectory `.\interfaces\fftw3x_cdft` in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the `make` command on Linux* OS or the `nmake` command on Windows* OS with a required target and optionally several parameters.

The target `libia32` or `libintel64` defines the platform architecture, and the other parameters specify the compiler, size of the default `INTEGER` type, as well as the name and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the `make` command is used to build the MPI FFTW wrappers to Intel® oneAPI Math Kernel Library (oneMKL) for use from the GNU C compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3x_cdft
make libintel64 compiler=gnu mpi=openmpi INSTALL_DIR=/my/path
```

This command builds the wrapper library using the GNU gcc compiler so that the final executable can use Open MPI, and places the result, named `libfftw3x_cdft_DOUBLE.a`, into directory `/my/path`.

Building an Application

Normally, the only change needed to build your application with MPI FFTW wrappers replacing original FFTW3 library is to add Intel® oneAPI Math Kernel Library (oneMKL) and the wrapper library at the link stage (see section "*Linking Your Application with Intel® oneAPI Math Kernel Library*" in the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*).

When you are recompiling your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

Running Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library for FFTW3. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw3xf_cdft` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

Parameters of the example makefiles are similar to the parameters of the wrapper library makefiles. Example makefiles normally build and invoke the examples. Results of running the examples are saved in subdirectory `.\_results` in files with extension `.res`.

For detailed information about options for the example makefile, refer to the makefile.

Appendix E: Code Examples

This appendix presents code examples of using some Intel® oneAPI Math Kernel Library (oneMKL) routines and functions.

Please refer to respective sections in the document for detailed descriptions of function parameters and operation.

BLAS Code Examples

Example. Using BLAS Level 1 Function

The following example illustrates a call to the BLAS Level 1 function `sdot`. This function performs a vector-vector operation of computing a scalar product of two single-precision real vectors *x* and *y*.

Parameters

n	Specifies the number of elements in vectors *x* and *y*.
incx	Specifies the increment for the elements of *x*.
incy	Specifies the increment for the elements of *y*.

```
program dot_main
real x(10), y(10), sdot, res
integer n, incx, incy, i
external sdot
n = 5
incx = 2
incy = 1
do i = 1, 10
  x(i) = 2.0e0
  y(i) = 1.0e0
end do
res = sdot (n, x, incx, y, incy)
print*, `SDOT = `, res
end
```

As a result of this program execution, the following line is printed:

SDOT = 10.000

Example. Using BLAS Level 1 Routine

The following example illustrates a call to the BLAS Level 1 routine `scopy`. This routine performs a vector-vector operation of copying a single-precision real vector *x* to a vector *y*.

Parameters

n	Specifies the number of elements in vectors *x* and *y*.
incx	Specifies the increment for the elements of *x*.
incy	Specifies the increment for the elements of *y*.

```
program copy_main
real x(10), y(10)
integer n, incx, incy, i
n = 3
incx = 3
incy = 1
do i = 1, 10
  x(i) = i
end do
call scopy (n, x, incx, y, incy)
print*, `Y = `, (y(i), i = 1, n)
end
```

As a result of this program execution, the following line is printed:

Y = 1.00000 4.00000 7.00000

Example. Using BLAS Level 2 Routine

The following example illustrates a call to the BLAS Level 2 routine `sger`. This routine performs a matrix-vector operation

```
a :=  alpha*x*y' + a.
```

Parameters

alpha	Specifies a scalar *alpha*.
x	*m*-element vector.
y	*n*-element vector.
a	*m*-by-*n* matrix.

```
program ger_main
real a(5,3), x(10), y(10), alpha
integer m, n, incx, incy, i, j, lda
m = 2
n = 3
lda = 5
incx = 2
incy = 1
alpha = 0.5
do i = 1, 10
  x(i) = 1.0
  y(i) = 1.0
end do
do i = 1, m
  do j = 1, n
    a(i,j) = j
  end do
end do
```

```
call sger (m, n, alpha, x, incx, y, incy, a, lda)
print*, `Matrix A: `
do i = 1, m
  print*, (a(i,j), j = 1, n)
end do
end
```

As a result of this program execution, matrix *a* is printed as follows:

Matrix A:

1.50000 2.50000 3.50000

1.50000 2.50000 3.50000

Example. Using BLAS Level 3 Routine

The following example illustrates a call to the BLAS Level 3 routine `ssymm`. This routine performs a matrix-matrix operation

```
c :=  alpha*a*b' + beta*c.
```

Parameters

alpha	Specifies a scalar *alpha*.
beta	Specifies a scalar *beta*.
a	Symmetric matrix
b	*m*-by-*n* matrix
c	*m*-by-*n* matrix

```
program symm_main
real a(3,3), b(3,2), c(3,3), alpha, beta
integer m, n, lda, ldb, ldc, i, j
character uplo, side
uplo = 'u'
side = 'l'
m = 3
n = 2
lda = 3
ldb = 3
ldc = 3
alpha = 0.5
beta = 2.0
do i = 1, m
  do j = 1, m
    a(i,j) = 1.0
  end do
end do
do i = 1, m
  do j = 1, n
    c(i,j) = 1.0
    b(i,j) = 2.0
  end do
end do
call ssymm (side, uplo, m, n, alpha,
a, lda, b, ldb, beta, c, ldc)
print*, `Matrix C: `
```

```
do i = 1, m
  print*, (c(i,j), j = 1, n)
end do
end
```

As a result of this program execution, matrix *c* is printed as follows:

Matrix C:

5.00000 5.00000

5.00000 5.00000

5.00000 5.00000

The following example illustrates a call from a C program to the Fortran version of the complex BLAS Level 1 function `zdotc()`. This function computes the dot product of two double-precision complex vectors.

Fourier Transform Functions Code Examples

This section presents code examples for functions described in the "FFT Functions" and "Cluster FFT Functions" subsections in the "Fourier Transform Functions" section. The examples are grouped in subsections

- Examples for FFT Functions, including Examples of Using Multi-Threading for FFT Computation
- Examples for Cluster FFT Functions
- Auxiliary data transformations.

FFT Code Examples

This section presents examples of using the FFT interface functions described in "Fourier Transform Functions".

Here are the examples of two one-dimensional computations. These examples use the default settings for all of the configuration parameters, which are specified in "Configuration Settings".

In the Fortran examples, the `use mkl_dfti` statement assumes that:

- The `mkl_dfti.f90` module definition file is already compiled.
- The `mkl_dfti.mod` module file is available.

One-dimensional In-place FFT

```
! Fortran example.
! 1D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X(32)
Real :: Y(34)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status
!...put input data into X(1),...,X(32); Y(1),...,Y(32)

! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,&
   DFTI_COMPLEX, 1, 32 )
Status = DftiCommitDescriptor( My_Desc1_Handle )
Status = DftiComputeForward( My_Desc1_Handle, X )
Status = DftiFreeDescriptor(My_Desc1_Handle)
! result is given by {X(1),X(2),...,X(32)}

! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor(My_Desc2_Handle, DFTI_SINGLE,&
   DFTI_REAL, 1, 32)
```

```
Status = DftiCommitDescriptor(My_Desc2_Handle)
Status = DftiComputeForward(My_Desc2_Handle, Y)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given in CCS format.
```

One-dimensional Out-of-place FFT

```
! Fortran example.
! 1D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X_in(32)
Complex :: X_out(32)
Real :: Y_in(32)
Real :: Y_out(34)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status
...put input data into X_in(1),...,X_in(32); Y_in(1),...,Y_in(32)
! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,
DFTI_COMPLEX, 1, 32 )
Status = DftiSetValue( My_Desc1_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor( My_Desc1_Handle )
Status = DftiComputeForward( My_Desc1_Handle, X_in, X_out )
Status = DftiFreeDescriptor(My_Desc1_Handle)
! result is given by {X_out(1),X_out(2),...,X_out(32)}
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor(My_Desc2_Handle, DFTI_SINGLE,
DFTI_REAL, 1, 32)
Status = DftiSetValue( My_Desc2_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor(My_Desc2_Handle)
Status = DftiComputeForward(My_Desc2_Handle, Y_in, Y_out)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given by Y_out in CCS format.
```

Two-dimensional FFT

The following is an example of two simple two-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

```
! Fortran example.
! 2D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex ::  X_2D(32,100)
Real :: Y_2D(34, 102)
Complex ::  X(3200)
Real :: Y(3468)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status, L(2)
!...put input data into X_2D(j,k), Y_2D(j,k), 1<=j=32,1<=k<=100
!...set L(1) = 32, L(2) = 100
```

```
!...the transform is a 32-by-100

! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,&
          DFTI_COMPLEX, 2, L)
Status = DftiCommitDescriptor( My_Desc1_Handle)
Status = DftiComputeForward( My_Desc1_Handle, X)
Status = DftiFreeDescriptor(My_Desc1_Handle)
! result is given by X_2D(j,k), 1<=j<=32, 1<=k<=100

! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc2_Handle, DFTI_SINGLE,&
          DFTI_REAL, 2, L)
Status = DftiCommitDescriptor( My_Desc2_Handle)
Status = DftiComputeForward( My_Desc2_Handle, Y)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given by the complex value z(j,k) 1<=j<=32; 1<=k<=100
! and is stored in CCS format
```

The following example demonstrates how you can change the default configuration settings by using the `DftiSetValue` function.

For instance, to preserve the input data after the FFT computation, the configuration of `DFTI_PLACEMENT` should be changed to "not in place" from the default choice of "in place."

The code below illustrates how this can be done:

Changing Default Settings

```
! Fortran example
! 1D complex to complex, not in place
Use MKL_DFTI
Complex :: X_in(32), X_out(32)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status
!...put input data into X_in(j), 1<=j<=32
Status = DftiCreateDescriptor( My_Desc_Handle,& DFTI_SINGLE, DFTI_COMPLEX, 1, 32)
Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X_in, X_out)
Status = DftiFreeDescriptor (My_Desc_Handle)
! result is X_out(1),X_out(2),...,X_out(32)
```

Using Status Checking Functions

This example illustrates the use of status checking functions described in "Fourier Transform Functions".

```
! Fortran
type(DFTI_DESCRIPTOR), POINTER :: desc
integer status
! ...descriptor creation and other code
status =  DftiCommitDescriptor(desc)
if (status .ne. 0) then
  if (.not. DftiErrorClass(status,DFTI_NO_ERROR) then
     print *, 'Error: ', DftiErrorMessage(status)
  endif
```

```
endif
```

Computing 2D FFT by One-Dimensional Transforms

Below is an example where a 20-by-40 two-dimensional FFT is computed explicitly using one-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

```
! Fortran
use mkl_dfti
Complex ::  X_2D(20,40)
Complex ::  X(800)
Equivalence (X_2D, X)
INTEGER :: STRIDE(2)
type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim1
type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim2
! ...
Status = DftiCreateDescriptor(Desc_Handle_Dim1, DFTI_SINGLE,&
                              DFTI_COMPLEX, 1, 20 )
Status = DftiCreateDescriptor(Desc_Handle_Dim2, DFTI_SINGLE,&
                              DFTI_COMPLEX, 1, 40 )
! perform 40 one-dimensional transforms along 1st dimension
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_NUMBER_OF_TRANSFORMS, 40 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_INPUT_DISTANCE, 20 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_OUTPUT_DISTANCE, 20 )
Status = DftiCommitDescriptor( Desc_Handle_Dim1 )
Status = DftiComputeForward( Desc_Handle_Dim1, X )
! perform 20 one-dimensional transforms along 2nd dimension
Stride(1) = 0; Stride(2) = 20
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_NUMBER_OF_TRANSFORMS, 20 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_DISTANCE, 1 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_DISTANCE, 1 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_STRIDES, Stride )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_STRIDES, Stride )
Status = DftiCommitDescriptor( Desc_Handle_Dim2 )
Status = DftiComputeForward( Desc_Handle_Dim2, X )
Status = DftiFreeDescriptor( Desc_Handle_Dim1 )
Status = DftiFreeDescriptor( Desc_Handle_Dim2 )
```

The following code illustrates real multi-dimensional transforms with CCE format storage of conjugate-even complex matrix. Example "Two-Dimensional REAL In-place FFT (Fortran Interface)" is two-dimensional in-place transform and Example "Two-Dimensional REAL Out-of-place FFT (Fortran Interface)" is two-dimensional out-of-place transform in Fortran interface. Note that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

Two-Dimensional REAL In-place FFT

```
! Fortran example.
! 2D and real to conjugate-even
Use MKL_DFTI
```

```
Real :: X_2D(34,100) ! 34  = (32/2 + 1)*2
Real :: X(3400)
Equivalence (X_2D, X)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_in(3)
Integer :: strides_out(3)
! ...put input data into X_2D(j,k), 1<=j=32,1<=k<=100
! ...set L(1) = 32, L(2) = 100
! ...set strides_in(1) = 0, strides_in(2) = 1, strides_in(3) = 34
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17
! ...the transform is a 32-by-100
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,&
DFTI_REAL, 2, L )
Status = DftiSetValue(My_Desc_Handle, DFTI_CONJUGATE_EVEN_STORAGE,&
DFTI_COMPLEX_COMPLEX)
Status = DftiSetValue(My_Desc_Handle, DFTI_INPUT_STRIDES, strides_in)
Status = DftiSetValue(My_Desc_Handle, DFTI_OUTPUT_STRIDES, strides_out)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X )
Status = DftiFreeDescriptor(My_Desc_Handle)
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in real matrix X_2D in CCE format.
```

Two-Dimensional REAL Out-of-place FFT

```
! Fortran example.
! 2D and real to conjugate-even
Use MKL_DFTI
Real :: X_2D(32,100)
Complex :: Y_2D(17, 100) ! 17 = 32/2 + 1
Real :: X(3200)
Complex :: Y(1700)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_out(3)

! ...put input data into X_2D(j,k), 1<=j=32,1<=k<=100
! ...set L(1) = 32, L(2) = 100
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17

! ...the transform is a 32-by-100
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,&
DFTI_REAL, 2, L )
Status = DftiSetValue(My_Desc_Handle,&
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE )
Status = DftiSetValue(My_Desc_Handle,&
DFTI_OUTPUT_STRIDES, strides_out)

Status = DftiCommitDescriptor(My_Desc_Handle)
Status = DftiComputeForward(My_Desc_Handle, X, Y)
Status = DftiFreeDescriptor(My_Desc_Handle)
```

```
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in complex matrix Y_2D in CCE format.
```

Examples of Using OpenMP* Threading for FFT Computation

The following sample program shows how to employ internal OpenMP* threading in Intel® oneAPI Math Kernel Library (oneMKL) for FFT computation.

To specify the number of threads inside Intel® oneAPI Math Kernel Library (oneMKL), use the following settings:

set `MKL_NUM_THREADS = 1` for one-threaded mode;

set `MKL_NUM_THREADS = 4` for multi-threaded mode.

Using oneMKL Internal Threading Mode (C Example)

```
/* C99 example */
#include "mkl_dfti.h"

float data[200][100];
DFTI_DESCRIPTOR_HANDLE fft = NULL;
MKL_LONG dim_sizes[2] = {200, 100};

/* ...put values into data[i][j] 0<=i<=199, 0<=j<=99 */

DftiCreateDescriptor(&fft, DFTI_SINGLE, DFTI_REAL, 2, dim_sizes);
DftiCommitDescriptor(fft);
DftiComputeForward(fft, data);
DftiFreeDescriptor(&fft);
```

The following Example “Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region” and Example “Using Parallel Mode with Multiple Descriptors Initialized in One Thread” illustrate a parallel customer program with each descriptor instance used only in a single thread.

Specify the number of OpenMP threads for Example “Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region” like this:

set `MKL_NUM_THREADS = 1` for Intel® oneAPI Math Kernel Library (oneMKL) to work in the single-threaded mode (recommended);

set `OMP_NUM_THREADS = 4` for the customer program to work in the multi-threaded mode.

Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region

Note that in this example, the program can be transformed to become single-threaded at the customer level but using parallel mode within Intel® oneAPI Math Kernel Library (oneMKL). To achieve this, you must set the parameter `DFTI_NUMBER_OF_TRANSFORMS = 4` and to set the corresponding parameter `DFTI_INPUT_DISTANCE = 5000`.

```
program fft2d_private_descr_main
  use mkl_dfti

  integer nth, len(2)
! 4 OMP threads, each does 2D FFT 50x100 points
  parameter (nth = 4, len = (/50, 100/))
  complex x(len(2)*len(1), nth)

  type(dfti_descriptor), pointer :: myFFT
```

```
  integer th, myStatus

! assume x is initialized and do 2D FFTs
!$OMP PARALLEL DO SHARED(len, x) PRIVATE(myFFT, myStatus)
  do th = 1, nth
    myStatus = DftiCreateDescriptor (myFFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len)
    myStatus = DftiCommitDescriptor (myFFT)
    myStatus = DftiComputeForward (myFFT, x(:, th))
    myStatus = DftiFreeDescriptor (myFFT)
  end do
!$OMP END PARALLEL DO
end
```

Specify the number of OpenMP threads for Example "Using Parallel Mode with Multiple Descriptors Initialized in One Thread" like this:

set `MKL_NUM_THREADS` = 1 for Intel® oneAPI Math Kernel Library (oneMKL) to work in the single-threaded mode (obligatory);

set `OMP_NUM_THREADS` = 4 for the customer program to work in the multi-threaded mode.

Using Parallel Mode with Multiple Descriptors Initialized in One Thread

```
program fft2d_array_descr_main
  use mkl_dfti

  integer nth, len(2)
! 4 OMP threads, each does 2D FFT 50x100 points
  parameter (nth = 4, len = (/50, 100/))
  complex x(len(2)*len(1), nth)

  type thread_data
    type(dfti_descriptor), pointer :: FFT
  end type thread_data
  type(thread_data) :: workload(nth)

  integer th, status, myStatus

  do th = 1, nth
    status = DftiCreateDescriptor (workload(th)%FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len)
    status = DftiCommitDescriptor (workload(th)%FFT)
  end do
! assume x is initialized and do 2D FFTs
!$OMP PARALLEL DO SHARED(len, x, workload) PRIVATE(myStatus)
  do th = 1, nth
    myStatus = DftiComputeForward (workload(th)%FFT, x(:, th))
  end do
!$OMP END PARALLEL DO
  do th = 1, nth
    status = DftiFreeDescriptor (workload(th)%FFT)
  end do
end
```

The following Example "Using Parallel Mode with a Common Descriptor" illustrates a parallel customer program with a common descriptor used in several threads.

Using Parallel Mode with a Common Descriptor

```
program fft2d_shared_descr_main
  use mkl_dfti
```

```
  integer nth, len(2)
! 4 OMP threads, each does 2D FFT 50x100 points
  parameter (nth = 4, len = (/50, 100/))
  complex x(len(2)*len(1), nth)
  type(dfti_descriptor), pointer :: FFT

  integer th, status, myStatus

  status = DftiCreateDescriptor (FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len)
  status = DftiCommitDescriptor (FFT)
! assume x is initialized and do 2D FFTs
!$OMP PARALLEL DO SHARED(len, x, FFT) PRIVATE(myStatus)
  do th = 1, nth
    myStatus = DftiComputeForward (FFT, x(:, th))
  end do
!$OMP END PARALLEL DO
  status = DftiFreeDescriptor (FFT)
end
```

Examples for Cluster FFT Functions

The following C example computes a 2-dimensional out-of-place FFT using the cluster FFT interface:

2D Out-of-place Cluster FFT Computation

```
/* C99 example */
#include "mpi.h"
#include "mkl_cdft.h"

DFTI_DESCRIPTOR_DM_HANDLE desc = NULL;
MKL_LONG v, i, j, n, s;
Complex *in, *out;
MKL_LONG dim_sizes[2] = {nx, ny};

MPI_Init(...);

/* Create descriptor for 2D FFT */
DftiCreateDescriptorDM(MPI_COMM_WORLD,
                       &desc, DFTI_DOUBLE, DFTI_COMPLEX, 2, dim_sizes);
/* Ask necessary length of in and out arrays and allocate memory */
DftiGetValueDM(desc,CDFT_LOCAL_SIZE,&v);
in = (Complex*) malloc(v*sizeof(Complex));
out = (Complex*) malloc(v*sizeof(Complex));
/* Fill local array with initial data. Current process performs n rows,
   0 row of in corresponds to s row of virtual global array */
DftiGetValueDM(desc, CDFT_LOCAL_NX, &n);
DftiGetValueDM(desc, CDFT_LOCAL_X_START, &s);
/* Virtual global array globalIN is defined by function f as
   globalIN[i*ny+j]=f(i,j) */
for(i = 0; i < n; ++i)
   for(j = 0; j < ny; ++j) in[i*ny+j] = f(i+s,j);
/* Set that we want out-of-place transform (default is DFTI_INPLACE) */
DftiSetValueDM(desc, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
/* Commit descriptor, calculate FFT, free descriptor */
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc, in, out);
/* Virtual global array globalOUT is defined by function g as
   globalOUT[i*ny+j]=g(i,j)   Now out contains result of FFT. out[i*ny+j]=g(i+s,j) */
DftiFreeDescriptorDM(&desc);
```

```
free(in);
free(out);
MPI_Finalize();
```

1D In-place Cluster FFT Computations

The C example below illustrates one-dimensional in-place cluster FFT computations effected with a user-defined workspace:

```
/* C99 example */
#include "mpi.h"
#include "mkl_cdft.h"

DFTI_DESCRIPTOR_DM_HANDLE desc = NULL;
MKL_LONG N, v, i, n_out, s_out;
Complex *in, *work;

MPI_Init(...);
/* Create descriptor for 1D FFT */
DftiCreateDescriptorDM(MPI_COMM_WORLD, &desc, DFTI_DOUBLE, DFTI_COMPLEX, 1, N);
/* Ask necessary length of array and workspace and allocate memory */
DftiGetValueDM(desc,CDFT_LOCAL_SIZE,&v);
in = (Complex*) malloc(v*sizeof(Complex));
work = (Complex*) malloc(v*sizeof(Complex));
/* Fill local array with initial data. Local array has n elements,
   0 element of in corresponds to s element of virtual global array */
DftiGetValueDM(desc, CDFT_LOCAL_NX, &n);
DftiGetValueDM(desc, CDFT_LOCAL_X_START, &s);
/* Set work array as a workspace */
DftiSetValueDM(desc, CDFT_WORKSPACE, work);
/* Virtual global array globalIN is defined by function f as globalIN[i]=f(i) */
for(i = 0; i < n; ++i) in[i] = f(i+s);
/* Commit descriptor, calculate FFT, free descriptor */
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in);
DftiGetValueDM(desc, CDFT_LOCAL_OUT_NX, &n_out);
DftiGetValueDM(desc, CDFT_LOCAL_OUT_X_START, &s_out);
/* Virtual global array globalOUT is defined by function g as globalOUT[i]=g(i)
   Now in contains result of FFT. Local array has n_out elements,
   0 element of in corresponds to s_out element of virtual global array.
   in[i]==g(i+s_out) */
DftiFreeDescriptorDM(&desc);
free(in);
free(work);
MPI_Finalize();
```

Auxiliary Data Transformations

This section presents C examples for conversion from the Cartesian to polar representation of complex data and vice versa.

Conversion from Cartesian to polar representation of complex data

```
// Cartesian->polar conversion of complex data
// Cartesian representation: z = re + I*im
// Polar representation: z = r * exp( I*phi )
```

```
#include <mkl_vml.h>

void
variant1_Cartesian2Polar(int n,const double *re,const double *im,
                         double *r,double *phi)
{
    vdHypot(n,re,im,r);         // compute radii r[]
    vdAtan2(n,im,re,phi);       // compute phases phi[]
}

void
variant2_Cartesian2Polar(int n,const MKL_Complex16 *z,double *r,double *phi,
                         double *temp_re,double *temp_im)
{
    vzAbs(n,z,r);               // compute radii r[]
    vdPackI(n, (double*)z + 0, 2, temp_re);
    vdPackI(n, (double*)z + 1, 2, temp_im);
    vdAtan2(n,temp_im,temp_re,phi); // compute phases phi[]
}
```

Conversion from polar to Cartesian representation of complex data

```
// Polar->Cartesian conversion of complex data.
// Polar representation: z = r * exp( I*phi )
// Cartesian representation: z = re + I*im
#include <mkl_vml.h>

void
variant1_Polar2Cartesian(int n,const double *r,const double *phi,
                         double *re,double *im)
{
    vdSinCos(n,phi,im,re);      // compute direction, i.e. z[]/abs(z[])
    vdMul(n,r,re,re);           // scale real part
    vdMul(n,r,im,im);           // scale imaginary part
}

void
variant2_Polar2Cartesian(int n,const double *r,const double *phi,
                         MKL_Complex16 *z,
                         double *temp_re,double *temp_im)
{
    vdSinCos(n,phi,temp_im,temp_re); // compute direction, i.e. z[]/abs(z[])
    vdMul(n,r,temp_im,temp_im); // scale imaginary part
    vdMul(n,r,temp_re,temp_re); // scale real part
    vdUnpackI(n,temp_re,(double*)z + 0, 2); // fill in result.re
    vdUnpackI(n,temp_im,(double*)z + 1, 2); // fill in result.im
}
```

Appendix F: oneMKL Functionality

This appendix provides an overview of the Intel® oneAPI Math Kernel Library (oneMKL) functionality on the different devices.

BLAS Functionality

Fortran

Functionality	CPU	OpenMP Offload Intel GPU
Level 1 BLAS (standard)	All	All
Level 2 BLAS (standard)	All	All
Level 3 BLAS (standard)	All	All
BLAS Extensions and Specializations	{AXPY,GEMM,TRSM}_BATCH (group and strided)	{AXPY,GEMM,TRSM}_BATCH (strided)
	GEMMT, AXPBY, GEMM3M	GEMMT
	Integer GEMM (s8u8)	N/A
	JIT GEMM API	N/A
	PACK GEMM API	N/A
	COMPACT GEMM API	N/A

Transposition Functionality

Functionality	CPU	OpenMP Offload Intel GPU
In-place dense matrix transpose	Yes	No
Out-of-place dense matrix transpose	Yes	No
In-place dense matrix add	Yes	No
Out-of-place dense matrix copy	Yes	No

LAPACK Functionality

NOTE All of the DPC++ LAPACK computational routines have a corresponding `*_scratchpad_size` function for calculating the required amount of scratchpad space.

LU Factorization Routines

Functionality	CPU	OpenMP Offload Intel GPU
getrf	Yes	Yes
getrs	Yes	Yes
getri	Yes	Yes

Cholesky Factorization Routines

Functionality	CPU	OpenMP Offload Intel GPU
potrf	Yes	Yes
potrs	Yes	Yes
potri	Yes	Yes

Orthogonal Factorization Routines

Functionality	CPU	OpenMP Offload Intel GPU
geqrf	Yes	Yes
{or,un}gqr	Yes	Yes
{or,un}mqr	Yes	Yes
gerqf	Yes	No
{or,un}mrq	Yes	No

Other Linear Equation Routines

Functionality	CPU	OpenMP Offload Intel GPU
trtrs	Yes	Yes
{sy,he}trf	Yes	No

Symmetric Eigenvalue Routines

Functionality	CPU	OpenMP Offload Intel GPU
{sy,he}ev	Yes	Yes
{sy,he}evd	Yes	Yes
{sy,he}evx	Yes	Yes
{sy,he}trd	Yes	Yes
{or,un}gtr	Yes	No
{or,un}mtr	Yes	No
steqr	Yes	Yes

Generalized Symmetric Eigenvalue Routines

Functionality	CPU	OpenMP Offload Intel GPU
{sy,he}gvd	Yes	Yes
{sy,he}gvx	Yes	Yes

Singular Value Routines

Functionality	CPU	OpenMP Offload Intel GPU
gesvd	Yes	Yes
gebrd	Yes	Yes
{or,un}gbr	Yes	No

Batched LAPACK Routines

Functionality	CPU	OpenMP Offload Intel GPU (ILP64 Interface)
getrf_batch	Strided	Strided
getrfnp_batch	Strided	Strided
getrs_batch	Strided	Strided
getrsnp_batch	Strided	Strided
getri_batch	No	No

Functionality	CPU	OpenMP Offload Intel GPU (ILP64 Interface)
potrf_batch	No	No
potrs_batch	No	No
geqrf_batch	No	No
{or,un}gqr_batch	No	No

Other LAPACK Routines

CPU	OpenMP Offload Intel GPU
Yes	No

DFT Functionality

DFTI Interfaces

Functionality	CPU	OpenMP Offload Intel GPU
Complex-to-Complex FFT transformations	Yes, 1D through 7D	Yes, 1D through 3D
Real-to-Complex FFT transformations	Yes, 1D through 7D	Yes, 1D through 3D

FFTW3 Interfaces

Functionality	CPU	OpenMP Offload Intel GPU
Complex-to-Complex FFT transformations	Yes, 1D through 7D	Yes, 1D through 3D
Real-to-Complex FFT transformations	Yes, 1D through 7D	No

FFTW2 Interfaces

Functionality	CPU	OpenMP Offload Intel GPU
Complex-to-Complex FFT transformations	Yes, 1D through 7D	No
Real-to-Complex FFT transformations	Yes, 1D through 7D	No

Sparse BLAS Functionality

In the following table for functionality, sm = sparse matrix, dm = dense matrix, sv = sparse vector, dv = dense vector, sc = scalar.

In the following table for operations, dense vectors = x, y, sparse vectors = w,v, dense matrices = X,Y, sparse matrices = A, B, C, and scalars = alpha, beta, d.

Level 1

Functionality	Operations	CPU	OpenMP Offload Intel GPU
Sparse Vector - Dense Vector addition (AXPY)	y <- alpha * w + y	Yes	No
Sparse Vector - Sparse Vector Dot product (SPDOT) (sv.sv -> sc)	d <- dot(w,v)	N/A	N/A
	dot(w,v) = sum(w_i* v_i)	No	No

Functionality	Operations	CPU	OpenMP Offload Intel GPU
	dot(w,v) = sum(conj(w_i) * v_i)	No	No
Sparse Vector - Dense Vector Dot product (SPDOT) (sv.dv -> sc)	d <- dot(w,x)	N/A	N/A
	dot(w,v) = sum(w_i* v_i)	Yes	No
	dot(w,v) = sum(conj(w_i) * v_i)	Yes	No
Dense Vector - Sparse Vector Conversion (sv <-> dv)	—	N/A	N/A
	x = scatter(w)	Yes	No
	w = gather(x,windx)	Yes	No

In the following table for functionality, sm = sparse matrix, dm = dense matrix, sv = sparse vector, dv = dense vector, sc = scalar.

In the following table for operations, dense vectors = x, y, sparse vectors = w,v, dense matrices = X,Y, sparse matrices = A, B, C, and scalars = alpha, beta, d.

Level 2

Functionality	Operations	CPU	OpenMP Offload Intel GPU
General Matrix-Vector multiplication (GEMV) (sm*dv->dv)	y <- beta*y + alpha * op(A)*x	N/A	N/A
	op(A) = A	Yes	No
	op(A) = A^T	Yes	No
	op(A) = A^H	Yes	No
Symmetric Matrix-Vector multiplication (SYMV) (sm*dv->dv)	y <- beta*y + alpha * op(A)*x	N/A	N/A
	op(A) = A	Yes	No
	op(A) = A^T	No	No
	op(A) = A^H	Yes	No
Triangular Matrix-Vector multiplication (TRMV) (sm*dv->dv)	y <- beta*y + alpha * op(A)*x	N/A	N/A
	op(A) = A	Yes	No
	op(A) = A^T	Yes	No
	op(A) = A^H	Yes	No
General Matrix-Vector mult with dot product (GEMVDOT) (sm*dv -> dv, dv.dv->sc)	y <- beta*y + alpha * op(A)*x, d = dot(x,y)	N/A	N/A
	op(A) = A	Yes	No
	op(A) = A^T	Yes	No
	op(A) = A^H	Yes	No
Triangular Solve (TRSV) (inv(sm)*dv -> dv)	solve for y, op(A)*y = alpha*x	N/A	N/A
	op(A) = A	Yes	No
	op(A) = A^T	Yes	No
	op(A) = A^H	Yes	No

In the following table for functionality, sm = sparse matrix, dm = dense matrix, sv = sparse vector, dv = dense vector, sc = scalar.

In the following table for operations, dense vectors = x, y, sparse vectors = w,v, dense matrices = X,Y, sparse matrices = A, B, C, and scalars = alpha, beta, d.

Level 3

Functionality	Operations	CPU	OpenMP Offload Intel GPU
General Sparse Matrix - Dense Matrix Multiplication (GEMM) (sm*dm->dm)	Y <- alpha*op(A)*op(X) + beta*Y	N/A	N/A
	op(A) = A, op(X) = X	Yes	No
	op(A) = A^T, op(X) = X	Yes	No
	op(A) = A^H, op(X) = X	Yes	No
	op(A) = A, op(X) = X^T	No	No
	op(A) = A^T, op(X) = X^T	No	No
	op(A) = A, op(X) = X^H	No	No
	op(A) = A^H	No	No
	op(A) = A^T, op(X) = X^H	No	No
	op(A) = A^H, op(X) = X^H	No	No
General Dense Matrix - Sparse Matrix Multiplication (GEMM) (dm*sm->dm)	Y <- alpha*op(X)*op(A) + beta*Y	N/A	N/A
	op(X) = X, op(A)=A	No	No
	op(X) = X^H, op(A)=A	No	No
	op(X) = X^H, op(A)=A	No	No
	op(X) = X, op(A)=A^H	No	No
	op(X) = X^H, op(A)=A^H	No	No
	op(X) = X^H, op(A)=A^H	No	No
	op(X) = X, op(A)=A^H	No	No
	op(X) = X^H, op(A)=A^H	No	No
	op(X) = X^H, op(A)=A^H	No	No
General Sparse Matrix - Sparse Matrix Multiplication (GEMM) (sm*sm->sm)	C <- alpha*op(A)*op(B) + beta*C	N/A	N/A
	op(A)=A, op(B)=B	Yes	No
	op(A)=A^T, op(B)=B	Yes	No
	op(A)=A^H, op(B)=B	Yes	No
	op(A)=A, op(B)=B^T	Yes	No
	op(A)=A^T, op(B)=B^T	Yes	No
	op(A)=A^H, op(B)=B^T	Yes	No
	op(A)=A, op(B)=B^H	Yes	No

Functionality	Operations	CPU	OpenMP Offload Intel GPU
	op(A)=A^T, op(B)=B^H	Yes	No
	op(A)=A^H, op(B)=B^H	Yes	No
General Sparse Matrix - Sparse Matrix Multiplication (GEMM) (sm*sm->dm)	Y <- alpha*op(A)*op(B) + beta*Y	N/A	N/A
	op(A)=A, op(B)=B	Yes	No
	op(A)=A^T, op(B)=B	Yes	No
	op(A)=A^H, op(B)=B	Yes	No
	op(A)=A, op(B)=B^T	No	No
	op(A)=A^T, op(B)=B^T	No	No
	op(A)=A^H, op(B)=B^T	No	No
	op(A)=A, op(B)=B^H	No	No
	op(A)=A^T, op(B)=B^H	No	No
	op(A)=A^H, op(B)=B^H	No	No
Symmetric Rank-K update (SYRK) (sm*sm->sm)	C <- op(A)*op(A)^H	N/A	N/A
	op(A)=A	Yes	No
	op(A)=A^T	Yes	No
	op(A)=A^H	Yes	No
Symmetric Rank-K update (SYRK) (sm*sm->dm)	Y <- op(A)*op(A)^H	N/A	N/A
	op(A)=A	Yes	No
	op(A)=A^T	Yes	No
	op(A)=A^H	Yes	No
Symmetric Triple Product (SYPR) (op(sm)*sm*sm -> sm)	C <- op(A)*B*op(A)^H	N/A	N/A
	op(A)=A	Yes	No
	op(A)=A^T	Yes	No
	op(A)=A^H	Yes	No
Triangular Solve (TRSM) (inv(sm)*dm -> dm)	solve for Y, op(A)*Y = alpha*X	N/A	N/A
	op(A)=A	Yes	No
	op(A)=A^T	Yes	No
	op(A)=A^H	Yes	No

In the following table for functionality, sm = sparse matrix, dm = dense matrix, sv = sparse vector, dv = dense vector, sc = scalar.

In the following table for operations, dense vectors = x, y, sparse vectors = w,v, dense matrices = X,Y, sparse matrices = A, B, C, and scalars = alpha, beta, d.

Other

Functionality	Operations	CPU	OpenMP Offload Intel GPU
Symmetric Gauss-Seidel Preconditioner (SYMGS) (update A*x=b, A=L+D+U)	x0 <- x*alpha; (L +D)*x1=b-U*x0; (U +D)*x=b-L*x1	Yes	No
Symmetric Gauss-Seidel Preconditioner with Matrix-Vector product (SYMGS_MV) (update A*x=b, A=L+D+U)	x0 <- x*alpha; (L +D)*x1=b-U*x0; (U +D)*x=b-L*x1; y=A*x	Yes	No
LU Smoother (LU_SMOOTHER) (update A*x=b, A=L+D+U, E~inv(D))	r=b-A*x; (L+D)*E*(U +D)*dx=r; y=x+dr	Yes	No
Sparse Matrix Add (ADD)	C <- alpha*op(A) + B	Yes	No
	op(A) = A^T	Yes	No
	op(A) = A^H	Yes	No

In the following table for operations, dense vectors = x, y, sparse vectors = w,v, dense matrices = X,Y, sparse matrices = A, B, C, and scalars = alpha, beta, d.

Helper Functions

Functionality	Operations	CPU	OpenMP Offload Intel GPU
Sort Indices of Matrix (ORDER)	N/A	Yes	No
Transpose of Sparse Matrix (TRANSPOSE)	A <- op(A) with op=trans or conjtrans	N/A	N/A
	transpose CSR/CSC matrix	Yes	No
	transpose BSR matrix	Yes	No
Sparse Matrix Format Converter (CONVERT)	N/A	Yes	No
Dense to Sparse Matrix Format Converter (CONVERT)	N/A	Yes	No
Copy Matrix Handle (COPY)	N/A	Yes	No
Create CSR Matrix Handle	N/A	Yes	No
Create CSC Matrix Handle	N/A	Yes	No
Create COO Matrix Handle	N/A	Yes	No
Create BSR Matrix Handle	N/A	Yes	No
Export CSR Matrix	Allows access to internal data in the CSR Matrix handle	Yes	No
Export CSC Matrix	Allows access to internal data in the CSC Matrix handle	Yes	No
Export COO Matrix	Allows access to internal data in the COO Matrix handle	Yes	No

Functionality	Operations	CPU	OpenMP Offload Intel GPU
Export BSR Matrix	Allows access to internal data in the BSR Matrix handle	Yes	No
Set Value in Matrix	N/A	Yes	No

Glossary

A^H	Denotes the conjugate transpose of a general matrix *A*. *See also* conjugate matrix.
A^T	Denotes the transpose of a general matrix *A*. *See also* transpose.

band matrix
: A general *m*-by-*n* matrix *A* such that $a_{ij} = 0$ for $|i - j| > l$, where $1 < l < \min(m, n)$. For example, any tridiagonal matrix is a band matrix.

band storage
: A special storage scheme for band matrices. A matrix is stored in a two-dimensional array: columns of the matrix are stored in the corresponding columns of the array, and *diagonals* of the matrix are stored in rows of the array.

BLAS
: Abbreviation for Basic Linear Algebra Subprograms. These subprograms implement vector, matrix-vector, and matrix-matrix operations.

BRNG
: Abbreviation for Basic Random Number Generator. Basic random number generators are pseudorandom number generators imitating i.i.d. random number sequences of uniform distribution. Distributions other than uniform are generated by applying different transformation techniques to the sequences of random numbers of uniform distribution.

BRNG registration
: Standardized mechanism that allows a user to include a user-designed BRNG into the VSL and use it along with the predefined VSL basic generators.

Bunch-Kaufman factorization
: Representation of a real symmetric or complex Hermitian matrix *A* in the form $A = PUDU^{H}P^{T}$ (or $A = PLDL^{H}P^{T}$) where *P* is a permutation matrix, *U* and *L* are upper and lower triangular matrices with unit diagonal, and *D* is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. *U* and *L* have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of *D*.

c
: When found as the first letter of routine names, `c` indicates the use of the single-precision complex data type.

CBLAS
: C interface to the BLAS. *See* BLAS.

CDF
: Cumulative Distribution Function. The function that determines probability distribution for univariate or multivariate random variable *X*. For univariate distribution the cumulative distribution function is the function of real argument *x*, which for every *x* takes a value equal to probability of the event $A: X \le x$. For multivariate distribution the cumulative distribution function is the function of a real vector $x = (x_1, x_2, \ldots, x_n)$, which, for every *x*, takes a value equal to probability of the event $A = (X_1 \le x_1 \ \& \ X_2 \le x_2, \ \& \ \ldots, \ \& \ X_n \le x_n)$.

Cholesky factorization
: Representation of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix *A* in the form $A = U^{H}U$ or $A = LL^{H}$, where *L* is a lower triangular matrix and *U* is an upper triangular matrix.

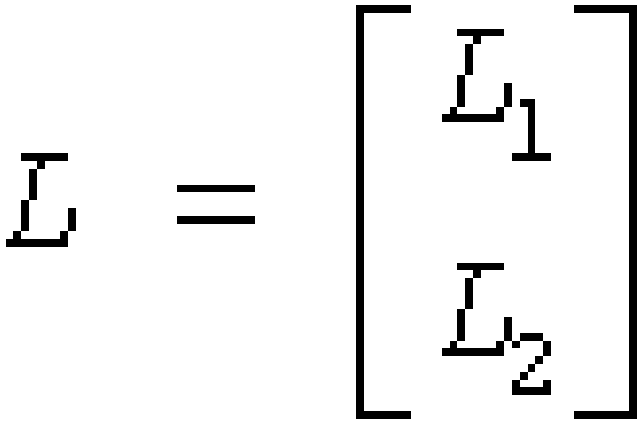
condition number
: The number $\kappa(A)$ defined for a given square matrix *A* as follows: $\kappa(A) = ||A|| \ ||A^{-1}||$.

conjugate matrix
: The matrix A^{H} defined for a given general matrix *A* as follows: $(A^{H})_{ij} = (a_{ji})^{*}$.

conjugate number
: The conjugate of a complex number $z = a + bi$ is $z^{*} = a - bi$.

d
: When found as the first letter of routine names, `d` indicates the use of the double-precision real data type.

dot product	The number denoted $x \cdot y$ and defined for given vectors *x* and *y* as follows: $x \cdot y = \Sigma_i x_i y_i$. Here x_i and y_i stand for the *i*-th elements of *x* and *y*, respectively.
double precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers *x* such that $2.23*10^{-308} < \| x \| < 1.79*10^{308}$. For this data type, the machine precision ε is approximately 10^{-15}, which means that double-precision numbers usually contain no more than 15 significant decimal digits. For more information, refer to *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture*.
eigenvalue	*See* eigenvalue problem.
eigenvalue problem	A problem of finding non-zero vectors *x* and numbers λ (for a given square matrix *A*) such that $Ax = \lambda x$. Here the numbers λ are called the eigenvalues of the matrix *A* and the vectors *x* are called the eigenvectors of the matrix *A*.
eigenvector	*See* eigenvalue problem.
elementary reflector(Householder matrix)	Matrix of a general form $H = I - \tau v v^T$, where *v* is a column vector and τ is a scalar. In LAPACK elementary reflectors are used, for example, to represent the matrix *Q* in the *QR* factorization (the matrix *Q* is represented as a product of elementary reflectors).
factorization	Representation of a matrix as a product of matrices. *See also* Bunch-Kaufman factorization, Cholesky factorization, *LU* factorization, *LQ* factorization, *QR* factorization, Schur factorization.
FFTs	Abbreviation for Fast Fourier Transforms. *See*"Fourier Transform Functions".
full storage	A storage scheme allowing you to store matrices of any kind. A matrix *A* is stored in a two-dimensional array *a*, with the matrix element a_{ij} stored in the array element $a(i,j)$.
Hermitian matrix	A square matrix *A* that is equal to its conjugate matrix A^H. The conjugate A^H is defined as follows: $(A^H)_{ij} = (a_{ji})^*$.
I	*See* identity matrix.
identity matrix	A square matrix I whose diagonal elements are 1, and off-diagonal elements are 0. For any matrix *A*, $AI = A$ and $IA = A$.
i.i.d.	Independent Identically Distributed.
in-place	Qualifier of an operation. A function that performs its operation in-place takes its input from an array and returns its output to the same array.
Intel® oneAPI Math Kernel Library (oneMKL)	Abbreviation for Intel® oneAPI Math Kernel Library.
inverse matrix	The matrix denoted as A^{-1} and defined for a given square matrix *A* as follows: $AA^{-1} = A^{-1}A = I$. A^{-1} does not exist for singular matrices *A*.
LQ factorization	Representation of an *m*-by-*n* matrix *A* as $A = LQ$ or $A = (L\ 0)Q$. Here *Q* is an *n*-by-*n* orthogonal (unitary) matrix. For $m \le n$, *L* is an *m*-by-*m* lower triangular matrix with real diagonal elements; for $m > n$,



where L_1 is an n-by-n lower triangular matrix, and L_2 is a rectangular matrix.

LU factorization
: Representation of a general m-by-n matrix A as $A = PLU$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).

machine precision
: The number ε determining the precision of the machine representation of real numbers. For Intel® architecture, the machine precision is approximately 10^{-7} for single-precision data, and approximately 10^{-15} for double-precision data. The precision also determines the number of significant decimal digits in the machine representation of real numbers. *See also* double precision and single precision.

MPI
: Message Passing Interface. This standard defines the user interface and functionality for a wide range of message-passing capabilities in parallel computing.

MPICH
: A freely available, portable implementation of MPI standard for message-passing libraries.

orthogonal matrix
: A real square matrix A whose transpose and inverse are equal, that is, $A^T = A^{-1}$, and therefore $AA^T = A^TA = I$. All eigenvalues of an orthogonal matrix have the absolute value 1.

packed storage
: A storage scheme allowing you to store symmetric, Hermitian, or triangular matrices more compactly. The upper or lower triangle of a matrix is packed by columns in a one-dimensional array.

PDF
: Probability Density Function. The function that determines probability distribution for univariate or multivariate continuous random variable X. The probability density function $f(x)$ is closely related with the cumulative distribution function $F(x)$.

  For univariate distribution the relation is

$$F(x) = \int_{-\infty}^{x} f(t)dt .$$

For multivariate distribution the relation is

$$F(x_1, x_2, \ldots, x_n) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \ldots \int_{-\infty}^{x_n} f(t_1, t_2, \ldots, t_n) dt_1 dt_2 \ldots dt_n .$$

positive-definite matrix
: A square matrix *A* such that $Ax \cdot x > 0$ for any non-zero vector *x*. Here · denotes the dot product.

pseudorandom number generator
: A completely deterministic algorithm that imitates truly random sequences.

QR factorization
: Representation of an *m*-by-*n* matrix *A* as $A = QR$, where *Q* is an *m*-by-*m* orthogonal (unitary) matrix, and *R* is *n*-by-*n* upper triangular with real diagonal elements (if $m \geq n$) or trapezoidal (if $m < n$) matrix.

random stream
: An abstract source of independent identically distributed random numbers of uniform distribution. In this manual a random stream points to a structure that uniquely defines a random number sequence generated by a basic generator associated with a given random stream.

RNG
: Abbreviation for Random Number Generator. In this manual the term "random number generators" stands for pseudorandom number generators, that is, generators based on completely deterministic algorithms imitating truly random sequences.

Rectangular Full Packed (RFP) storage
: A storage scheme combining the full and packed storage schemes for the upper or lower triangle of the matrix. This combination enables using half of the full storage as packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels as the full storage.

s
: When found as the first letter of routine names, `s` indicates the use of the single-precision real data type.

ScaLAPACK
: Stands for Scalable Linear Algebra PACKage.

Schur factorization
: Representation of a square matrix *A* in the form $A = ZTZ^H$. Here T is an upper quasi-triangular matrix (for complex *A*, triangular matrix) called the Schur form of *A*; the matrix *Z* is orthogonal (for complex *A*, unitary). Columns of *Z* are called Schur vectors.

single precision
: A floating-point data type. On Intel® processors, this data type allows you to store real numbers *x* such that $1.18*10^{-38} < |x| < 3.40*10^{38}$. For this data type, the machine precision (ε) is approximately 10^{-7}, which means that single-precision numbers usually contain no more than 7 significant decimal digits. For more information, refer to *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture*.

singular matrix	A matrix whose determinant is zero. If A is a singular matrix, the inverse A^{-1} does not exist, and the system of equations $Ax = b$ does not have a unique solution (that is, there exist no solutions or an infinite number of solutions).
singular value	The numbers defined for a given general matrix A as the eigenvalues of the matrix AA^H. *See also* SVD.
SMP	Abbreviation for Symmetric MultiProcessing. Intel® oneAPI Math Kernel Library (oneMKL) offers performance gains through parallelism provided by the SMP feature.
sparse BLAS	Routines performing basic vector operations on sparse vectors. Sparse BLAS routines take advantage of vectors' sparsity: they allow you to store only non-zero elements of vectors. *See* BLAS.
sparse vectors	Vectors in which most of the components are zeros.
storage scheme	The way of storing matrices. *See* full storage, packed storage, and band storage.
SVD	Abbreviation for Singular Value Decomposition. *See also* Singular value decomposition section in "LAPACK Auxiliary and Utility Routines".
symmetric matrix	A square matrix A such that $a_{ij} = a_{ji}$.
transpose	The transpose of a given matrix A is a matrix A^T such that $(A^T)_{ij} = a_{ji}$ (rows of A become columns of A^T, and columns of A become rows of A^T).
trapezoidal matrix	A matrix A such that $A = (A_1 A_2)$, where A_1 is an upper triangular matrix, A_2 is a rectangular matrix.
triangular matrix	A matrix A is called an upper (lower) triangular matrix if all its subdiagonal elements (superdiagonal elements) are zeros. Thus, for an upper triangular matrix $a_{ij} = 0$ when $i > j$; for a lower triangular matrix $a_{ij} = 0$ when $i < j$.
tridiagonal matrix	A matrix whose non-zero elements are in three diagonals only: the leading diagonal, the first subdiagonal, and the first super-diagonal.
unitary matrix	A complex square matrix A whose conjugate and inverse are equal, that is, that is, $A^H = A^{-1}$, and therefore $AA^H = A^H A = I$. All eigenvalues of a unitary matrix have the absolute value 1.
VML	Abbreviation for Vector Mathematical Library. *See*"Vector Mathematical Functions".
VSL	Abbreviation for Vector Statistical Library. *See*"Statistical Functions".
z	When found as the first letter of routine names, `z` indicates the use of the double-precision complex data type.

Notices and Disclaimers

Intel technologies may require enabled hardware, software or service activation.
